

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

THE NEW AMERICAN CYCLOPÆDIA.

SPIRITUALISM

SPIRITUALISM, a term formerly used to designate the doctrines and religious life of a class of mystics who professed to be under the sensible guidance of the Divine Spirit, and who were distinguished by a habit of spiritualizing the Sacred Scriptures. Jacob Böhme, Mme. Guyon, Miguel de Molinos, and Mme. de Bourignon, though not all ostensibly of the same communion, are representatives of the somewhat numerous class of religionists, particularly of the 17th century, to whose teachings and practice the appellation of spiritualism has been applied. Latterly, however, especially in the United States, the word has been employed exclusively to designate the belief in and practice of open intercourse with the spiritual world. This alleged intercourse has attained an extraordinary development in recent times, and especially since about the year 1848. Although it was not until that period that the so called spiritual manifestations assumed a form and conspicuousness which forced them into universal notice, it is asserted that many startling instances of them, as precursors and prophets of the more signal wonders, had been in the course of development during many years previous; and that, in fact, the spiritualism of the day is the growth of a century. We are referred to the alleged fact that 100 years ago Emanuel Swedenborg was in full and open communication with the spiritual world, and in daily converse with spirits and angels, with all the familiarity with which man converses with man. There is also a tradition that while Swedenborg was on his deathbed, he was asked by a friend whether in that solemn hour he still adhered to the statements and doctrines set forth in his books; when he answered emphatically in the affirmative, adding that in about 80 years from that time events would occur that would greatly tend to bring his teachings into general notice. It is noted by spiritualists as a singular coincidence that the 80 years from that time (1772) expired in 1852, at which time the alleged spiritual phenomena, corroborating in many respects what Swedenborg had taught concerning spirits and the spiritual world, were exciting universal attention. In his book on

"Divine Love and Wisdom" (paragraph 257) Swedenborg avers that a man in whom the spiritual degree of the mind is open may come into angelic wisdom "by laying asleep the sensations of the body, and by influx from above at the same time into the spirituals of his mind."—Clairvoyance appears to have played an important part in the introduction of modern spiritualism, and a historical sketch of the latter, to be complete, must include some notice of the former. Jung-Stilling, in his various writings on pneumatology early in the present century, appears to have been the first to notice that clairvoyants, during their more exalted states of *ecstasis*, professed, with what seemed to him satisfactory evidence, to be in converse with invisible intelligences. The same claims to open intercourse with the spiritual world, with many phenomenal evidences which he regarded as establishing their truth, were afterward noted by Dr. Justinus Kerner, and detailed at large in his biography of one of his patients, Frederica Hauffe, more familiarly known as the seeress of Prevorst, and who is said to have been in a magnetic state for most of the time during the last 7 years of her life, describing the persons and repeating the language of what she represented to be spirits, and being often accompanied with mysterious rapping sounds. Many similar instances of alleged intercourse with the invisible world through clairvoyance subsequently occurred, not only in Germany and other parts of Europe, but in the United States; but none of these phenomena were of so remarkable a character as those presented in the case of Andrew Jackson Davis. (See DAVIS, ANDREW JACKSON.) Thrown into an abnormal state of mind and body by the process of magnetism, this young man, while professing to be in immediate converse with the spiritual world, dictated a large 8vo. volume which was published under the title of "The Principles of Nature, her Divine Revelations, and a Voice to Mankind." In a portion of this book that was dictated in the autumn of 1846 (pp. 675-'6) the entranced author distinctly predicted that the communication with the spiritual world would ere long assume "the

form of a living demonstration." The same prediction is said to have been frequently repeated by the young clairvoyant in his interviews with his visitors. Another event is spoken of as possessing some significance in connection with this history. In the spring of 1848, the societies of Shakers at New Lebanon and Watervliet, N. Y., and several other communities of that fraternity, almost simultaneously became the subjects of strange psychological experiences, during which certain of the members would lose all personal consciousness, while influences purporting to be the spirits of persons of different nations, and who had lived in the world in different ages, took possession of their bodies, and spoke through their vocal organs. Shakers who personally witnessed these phenomena describe them as being very impressive, and a constant burden of their communications was: "Treasure these things up in your hearts; say nothing of them, for the present, to the world's people, but the time is not far distant when these same wonders which you now behold shall be witnessed extensively in the world." These manifestations continued for a year or more, when they suddenly ceased, the alleged spirits bidding the "brethren" farewell, with a promise to come again before many years, when their manifestations should be addressed not merely to a select few, but to the world in general.—The commencement of the "spirit-rapping" phenomenon was as follows: Some time in the year 1847 the attention of Mr. Michael Weekman, who resided in the little village of Hydesville in the township of Arcadia, Wayne co., N. Y., was called to certain rapping sounds upon the door of his house, which he was unable by the most diligent efforts to trace to any visible cause. Mr. Weekman soon afterward vacated the house, and the family of Mr. John D. Fox moved into it. In the latter part of March, 1848, this family was startled by mysterious rappings that were heard nightly upon the floor of one of the bedrooms, and sometimes in other parts of the house. They endeavored to trace the sounds to their cause, but failed. On the night of March 31, having been broken of their rest for several nights previous, they retired to bed earlier than usual, hoping to be permitted to sleep without disturbance. The sounds, however, were resumed, and, occurring near the bed occupied by two of the daughters, the youngest girl, then about 10 years old, attempted to imitate them by the snapping of her fingers. Whenever she would snap her fingers, the raps would immediately respond by the same number of sounds. One of the girls then said: "Now do as I do; count 1, 2, 3, 4, 5, 6," at the same time striking her hands together. The same number of raps responded, and at similar intervals. The mother of the girls then said: "Count 10;" and 10 distinct raps were heard; "Count 15," and that number of sounds followed. She then said: "Tell us the age of Cathy [the youngest daughter] by rapping one for each year," and the

number of years was rapped correctly. Then, in like manner, the age of each of the other children was by request indicated by this invisible agent. Startled and somewhat alarmed at these manifestations of intelligence, Mrs. Fox asked if it was a human being that was making that noise, and if it was to manifest it by making the same noise. There was no sound. She then said: "If you are a spirit, make two distinct sounds." Two raps were accordingly heard. The members of the family by this time had all left their beds, and the house was again thoroughly searched, as it had been before, but without discovering any thing that could explain the mystery; and after a few more questions, and responses by raps, the neighbors were called in to assist in further efforts to trace the phenomenon to its cause; but these persons were no more successful than the family had been, and they confessed themselves thoroughly confounded. For several subsequent days the village was in a turmoil of excitement, and multitudes visited the house, heard the raps, and interrogated the apparent intelligence which controlled them, but without obtaining any clue to the discovery of the agent, further than its own persistent declaration that it was a spirit. About 8 weeks after these occurrences, David, a son of Mr. and Mrs. Fox, went alone into the cellar where the raps were then being heard, and said: "If you are the spirit of a human being, who once lived on the earth, can you rap to the letters that will spell your name? and if so, rap now 8 times." Three raps were promptly given, and David proceeded to call the alphabet, writing down the letters as they were indicated, and the result was the name "Charles B. Rosma," a name quite unknown to the family, and which they were afterward unable to trace. The statement was in like manner obtained from the invisible intelligence, that he was the spirit of a peddler who had been murdered in that house some years previous. At first, we are told, the raps occurred in the house even when all the members of the family were absent, but subsequently they occurred only in the presence of the two younger daughters, Oatharine and Margaretta. Soon after these occurrences the family removed to Rochester, at which place the manifestations still accompanied them; and here it was discovered, by the rappings at the letters of the alphabet in the manner before described, that different spirits were apparently using this channel of communication, and that in short almost any one, on coming into the presence of the two girls, could get a communication from what purported to be the spirits of his departed friends, the same often being accompanied by tests which satisfied the interrogator as to the spirit's identity. A new phenomenon was also observed in the frequent movement of tables and other ponderable bodies without appreciable agency, in the presence of these two young girls. These manifestations, growing more and more remarkable, attracted

numerous visitors, some from long distances, and the phenomenon began, as it were, to propagate itself, and to be witnessed in other families in Rochester and vicinity, while, as coincident therewith, susceptible persons would sometimes fall into apparent trances, and become clairvoyant, and reaffirm these raps and physical movements to be the productions of spirits. In Nov. 1849, at the request of the alleged spirits, a public meeting was called in Corinthian hall, Rochester, for the purpose of submitting these phenomena to the investigation of a committee to be appointed by the audience, with a view to the publication of a report concerning their nature and claims, whatever the decision respecting these might be. The Misses Fox appeared upon the stage, the phenomena were freely manifested and were subjected to many tests, and a committee appointed for their investigation, after having continued their experiments there and elsewhere for several days, reported that they were unable to trace them to any mundane agency. From that time, and especially from the time the Fox girls arrived in New York city in the following month of May, the alleged spiritual manifestations became the subject of extensive newspaper and conversational discussion; their facts were published far and wide; "mediums," through whom they were said to occur, sprang up in different parts of the country, and were multiplied by hundreds and almost by thousands; and for several years spiritualism constituted one of the most prominent themes of public discussion. Among the mediums of the alleged spiritual manifestations there have been representatives from all classes and conditions of mankind, male and female, high and low, rich and poor, learned and unlearned; and even little children in their swaddling clothes are said to have been, in some few instances, mediums for the raps. The alleged mediums have been classified as rapping mediums; mediums for tipping and turning tables by a slight touch of the finger; mediums for the movement of ponderable bodies without contact; mediums for the production of phosphorescent lights in a dark room; mediums for playing on musical instruments in a manner beyond their ordinary abilities; mediums for involuntary writing; impressional speaking, seeing, hearing, personating, and healing mediums; mediums in whose presence are produced drawings, and pictures in colors, and writings, and also in many instances tangible and visible living human forms; and mediums for the development of other mediums. By the raps and tipping of tables, and by the control of the medium's organs to write and speak, the spirits are supposed to express their own peculiar intelligence in a degree of perfection proportioned to the development and passivity of the medium; and it is averred that persons while under the spiritual afflatus have often spoken in foreign tongues which they had never learned; and writings in languages to them unknown

have, in a few instances, been produced in their presence, as we are told, by invisible hands. Mediums for the movement of ponderable bodies without hands, are said to be sometimes also mediums for the preternatural movement of their own bodies; and intelligent and respectable persons testify that they have seen the medium Henry Gordon float in air several feet above the floor, for several minutes, without the slightest physical contact or support, he being at the time deeply entranced. Individuals long deceased, it is said, have often been personated by mediums so that their surviving friends would instantly recognize them, and their earthly history has been accurately detailed, though the mediums may never have known nor heard of them. Persons report that the spirits of their departed friends have been seen and correctly described, and their words repeated, though to all but the medium they were invisible and inaudible; and obstinate diseases, on which the skill of the physician has been exhausted in vain, are said to have been quickly cured simply by the imposition of the hands of the medium while under spirit influence. Spiritualists admit that many impositions have been practised under the name of spiritual manifestations, but they aver that in most instances cheats could not have been palmed off even if designed, and that in other cases there could be no possible motive for deception, as the investigations were carried on in private families, while the mediums were their own sons and daughters. The "Spiritual Register" for 1859 estimates the number of actual spiritualists in America at 1,500,000; those who have more or less faith in the doctrine, but do not openly espouse it, 4,000,000; public advocates, 1,000; mediums, public and private, 40,000; places for public meetings, 1,000; books and pamphlets, 500; periodicals, 80. Spiritualists, however, are not associated under any regular organization, but have their representatives among all sects and parties of religionists and non-religionists, and these estimates of their numbers can be considered as only approximately correct.—Spiritualism numbers among its avowed converts in America many persons well known in the walks of science, philosophy, literature, and statesmanship. While it has its converts from every religious denomination, no small proportion of its advocates are from the ranks of those who previously doubted or totally disbelieved the immortality of the soul, and who affirm that they carry their sceptical tendencies into the investigation of this subject. On matters of speculative theology, there seems to be among them the widest latitude of opinion, though a majority of them perhaps are in their speculations inclined to what may be termed a sublimated naturalism. They tell us that it is not the object of the spirits to teach theological dogmas as by any authority superior to that of man, but rather, by the mental and physical phenomena incidentally presented in the course of their manifestations, to

furnish those elements of reasoning from which each one may work out his own conclusions; while we are told that the main object of their manifestations is to furnish actual demonstration of the immortality of the soul and of some of the conditions and laws of the *post mortem* existence.—Spiritualism has also made considerable progress in Europe, especially in England and France. In England, it is stated, many of the nobility as well as of the intelligent middle classes are believers in it, and hold communications with their departed friends through mediums in their own families. Several books and pamphlets have been published on the subject in that country, and a semi-monthly periodical is issued in London devoted to its facts and philosophy. In France its believers are still more numerous. Several able journals devoted to the subject are published in Paris, and read throughout France, Switzerland, and Belgium. Germany, Spain, Italy, Russia, and in short nearly every nation of Europe, appears to have its devotees of spiritualism, in greater or smaller numbers. Travellers in the north of Africa tell us that it has made considerable progress in the Barbary states; and reports from China represent it as having very distinctly appeared at several localities within that empire, and especially at the city of Shanghai, about the time of its first advent in America.—For specimens of the better kind of spirit communications, considered as literary productions, see "Spiritualism," by the Hon. John W. Edmonds and G. T. Dexter, M.D. (2 vols. 8vo., New York, 1864-5); "The Healing of the Nations," by Charles Linton, with introduction and appendix by N. P. Tallmadge, late U. S. senator and governor of Wisconsin (8vo., New York, 1855); "Scenes in the Spirit World, or Life in the Spheres," by Hudson Tuttle, medium (12mo., New York, 1855). Among books produced in the ordinary manner, the following may be consulted: "Experimental Investigations of the Spirit Manifestations," by Prof. Robert Hare (8vo., New York, 1856); "A Discussion of the Facts and Philosophy of Ancient and Modern Spiritualism," by S. B. Brittan and B. W. Richmond, M.D.; "Modern Spiritualism, its Facts and Fanaticisms," &c., by E. W. Capron (8vo., Boston, 1855). With the exception of these and a few other books, the best portion of the literature of spiritualism is to be found in the various periodical publications devoted to that subject.

SPITZBERGEN, a group of 4 principal and several smaller islands in the Arctic ocean, the northernmost land yet discovered, between lat. 76° 30' and 80° 30' N. and long. 9° and 22° E., and about midway between Greenland on the W. and Nova Zembla on the E.; area, about 22,000 sq. m. The large islands are Spitzbergen, North-East Land, South-East Land, and Charles. On the E. of Spitzbergen proper is a peninsula called New Friesland or East Spitzbergen. The island is very mountainous, some of the peaks rising to the height of 3,000 or 4,000 feet above the level of the sea. On

Charles island are 5 summits ranging from 4,000 to 4,500 feet high. The N. shores of Spitzbergen and North-East Land are more level, and here and on several of the smaller islands some soil is found, in which a few very diminutive plants spring up and mature in a month or 6 weeks of the short summer. Immense glaciers abound, and the islands are almost covered with perpetual snow. The mean temperature of the 3 warmest months is 34.5°. For 4 months of the year the sun does not rise, but the long night is relieved by a faint twilight, and the occasional brilliant light of the aurora borealis; the moon and stars also shine here with great brightness. The islands are frequented by great multitudes of sea fowl, as well as by polar bears, foxes, and reindeer. Marble and coal of a good quality are found. The neighboring seas abound with whales, seals, and walruses, which are taken in large numbers by the vessels that visit this inhospitable region; and Russian whalers have lived for years on the islands.—These islands are supposed to have been first discovered by Wiloughby in 1553; but their discovery is generally dated from the visit of Barentz, the Dutch navigator, in 1596, in his search for a N. E. passage to the Pacific, who named the principal island Spitzbergen (pointed mountains) from its numerous sharp peaks. Their sovereignty is claimed by Russia. A Swedish scientific expedition under Prof. Torell explored Spitzbergen in the summer of 1861, whose report is expected to form an important addition to the previous knowledge of that region.

SPLEEN (Gr. σπλήν), the largest of the vascular or ductless glands, whose probable functional office is subsidiary to the process of sanguification. It is situated in the left hypochondriac region, below the diaphragm, above the descending colon, between the cartilages of the false ribs and the cardiac extremity of the stomach, to which it is united by short vessels. It is in health from 3½ to 4½ inches long and 2½ thick, of an elongated flattened form, and about 7 oz. in weight; on the inner surface is a longitudinal groove in which are situated the blood vessels, posteriorly resting on the vertebral column; below it is in relation with the left kidney and capsule, and with the pancreas behind. It is soft, spongy, and dusky red; the external surface is covered with the peritoneum; beneath this is a coat of white fibrous tissue with some elastic fibres, from the inner surface of which extends through the entire organ a network of fibrous bands and threads, the trabecular tissue. The splenic artery comes from the celiac axis, the trunks not anastomosing, but subdividing like the branches of a tree, to which the Malpighian corpuscles are attached as fruits on short peduncles, ending generally in capillaries with very thin walls, passing in every direction through the organ and into the interior of the corpuscles; but in man, according to Mr. Gray, the capillaries frequently disappear, and the blood passes from

arteries to veins through *lacunae* or mere channels in the pulp tissue. The veins are branched like the arteries, have no valves, and the principal stem is one of the trunks of the vena portæ; the nerves form the splenic plexus, and proceed from the solar plexus; the lymphatics are few and superficial. The parenchyma consists of a homogeneous mass of colorless nucleated corpuscles and cells imbedded in a granular plasma, in various stages of rapid development and change; this is in the greatest quantity toward the end of the digestive process, when a large amount of fresh alimentary material is introduced into the circulation. The splenic corpuscles, or Malpighian bodies of the spleen, are whitish spherical bodies, varying in diameter from $\frac{1}{4}$ to $\frac{1}{2}$ of a line, largest and most numerous in healthy and well fed individuals and animals. There are colored cells in the spleen pulp, chiefly red blood corpuscles in various stages of degeneration, and a few pigment cells. It is proportionately the largest and most active in early and vigorous manhood; it is found in all classes of vertebrates, and of various shapes and sizes. The great amount of blood sent to the spleen, its minute distribution, and the contents of the glandular vesicles, show that cell growth proceeds rapidly in its substance; their products, however, are returned in an altered state to the blood, passing through the liver before entering the vena cava. It is probably a storehouse of albuminous nutritive material for the formative operations, which may be drawn upon as the system requires it, and with the absorbent glands probably assists in supplying the germs of the blood corpuscles. It is also generally believed to serve as an organ for the relief of the portal circulation, preventing undue accumulation of blood in the liver by the ease with which its vessels are distended. Obstruction of the circulation in the liver affects the spleen directly; when the alimentary canal is distended with food, were it not for the spleen the portal system would be gorged with blood; the general internal venous congestion which results from the cold stage of intermittent fever, it is well known, causes a permanent enlargement of the spleen. Its presence is not essential to life, at least in the adult; it has often been removed in animals, and in a few instances in man, without apparent ill consequences, its functions probably being performed by the other ductless or even the lymphatic glands. (See GLAND.) Almost every one has experienced a sharp pain or stitch under the ribs of the left side, after violent or long continued running and active exercise; this is caused by distention of the spleen by the blood obstructed in its passage through the liver; a similar pain is felt in the cold stage of fever and ague. It is sometimes greatly enlarged, as in the last mentioned disease and in typhoid fever, and it is engorged and softened in scurvy; in its chronic diseases, the face is apt to assume a dull ashy white color, seen also in

the eyes; it is subject to inflammation, generally from external injury, with pain, tenderness on pressure, and fever, requiring antiphlogistic treatment. The spleen was by the ancients supposed to be the source of black bile, which predisposed to and produced the melancholy temperament; and the terms "spleen" and "splenetic" are to this day employed to describe the ill-natured, fretful, and desponding state of mind commonly called "the blues;" it is hardly necessary to say that there is no connection between the spleen and the above temperament.

SPOHR, LUDWIG, a German composer, born in Brunswick, April 5, 1784, died there, Oct. 22, 1859. In early youth he devoted much attention to the study of the violin, his skill in performing on which, when practically tested at the congress of Vienna in 1814, was declared superior to that of any of his rivals. Subsequently he gave concerts for several years in various parts of Europe, and in 1822 established himself in Cassel as chapelmaster of the elector, in whose service he remained until near the close of his life. He produced a great number of orchestral symphonies, concertos, quartets, and other instrumental works, and cantatas, songs, ballads, and other vocal pieces, which are popular throughout Germany; but his reputation rests chiefly on his operas, "The Mountain Spirit," "The Alchemist," "The Crusaders," "Jesonda," "Faust," "Zemira and Azor," and "Pietro of Abano;" and on his oratorios, "The Last Judgment," "The Crucifixion," and "The Fall of Babylon," which are among the finest works of their class produced since the time of Handel. His symphony entitled "The Consecration of Tones" is also a great favorite in the concert room. Forty years before his death he discontinued performing on the violin, but left to violin players an admirable treatise on the subject, entitled "The Violin School." During the latter years of his life he composed little.

SPOLETO, formerly a delegation of the Papal States, now belonging to the kingdom of Italy, bordering on the Neapolitan territory; area, 1,180 sq. m.; pop. in 1853, 184,939. It is drained by the rivers Tronto, Tiber, Nera, Corno, and Velino. The valley of Spoleto is very fertile, and produces large quantities of maize, wine, olives, melons, and silk. Under the new organization Spoleto is a district of reduced size in the province of Umbria; pop. 70,011.—SPOLETO (anc. *Spolietum* or *Spoleturnum*), the capital, is situated on the side of a mountain overlooking the Tessino, about 75 m. N. from Rome; pop. about 7,000. It is defended by a strong castle, which is separated from the city by a very deep and narrow ravine crossed by a single bridge of great height. The city has a fine cathedral of marble, in the style of the early renaissance. Among its numerous ruins are those of an ancient theatre, of a temple of Concord, and a palace of Theodorico. There is also an old aqueduct attributed to the

Romans, and a triumphal arch called the "gate of Hannibal." The town has considerable trade in grain, wine, raisins, leather, and horses. Under the Romans Spoletium was a flourishing town of the province of Umbria. Hannibal was repulsed under its walls. After the fall of the western empire it fell into the power of the Goths, was taken from them by Narses, subsequently became the capital of a Lombard duchy, and in the 18th century was annexed to the Papal dominions. It was sacked by Frederic Barbarossa, and again destroyed by the Perugians in 1824. Napoleon I. made it the capital of the department of Trasimène. It has suffered much from earthquakes.

SPONDEE (Gr. σπονδή, a libation), a poetical foot of 2 long syllables. Verses exclusively spondaic have a slow movement, and consequent solemnity; such were sung by the Greeks on sacrificial occasions, and when a libation was offered, and hence the name. The spondee is used in any part of the English heroic line, but with the best effect in the first and last places.

SPONGE, the familiar name of the family of *spongiada* or *porifera*, a division of animals of the so called class *protozoa*. It has long been a disputed point whether sponges are animals or vegetables; in the "Principles of Zoology," by Agassiz and Gould (1848), they are said to belong to the vegetable kingdom; the most recent authorities, as Johnston and Bowerbank, decide in favor of their animal nature. Whatever may be the decision of this question, the common sponge (*spongia*, Linn.) may be taken as the type. These consist of a soft gelatinous mass, porous and elastic, supported on a fibro-corneous skeleton which anastomoses in all directions, and without silicious or calcareous spicula; they have no organs nor vessels, are capable of absorbing great quantities of fluid which is given out again on pressure, insensible to all kinds of irritation, and incapable of contraction or locomotion. The apparently homogeneous jelly which fills the pores of the living sponge and covers its surface, is seen under the microscope to be filled with numerous transparent spherical granules. There is a gradual passage from the soft sponges of commerce to those of stiff and compact texture, with the fibres loaded with silicious spicula, crumbling easily when dry, and useless in the arts; others are rather of a felted character, usually grayish white, and loaded with variously shaped spicula of carbonate of lime. Sponges vary much in form, and are fixed by a kind of root at the base, or incrust other bodies, growing mostly in groups; most are marine, but *spongilla* (Lam.) grows in fresh water; they often possess brilliant colors. Rounded orifices of large size, or *oscula*, are scattered over the surface of most sponges, which lead into sinuous canals permeating the substance in every direction; water is continually absorbed by the pores of the sponge, penetrating and filling every part, and, having supplied air and food, is driven out through the oscula; the currents

are kept up principally by the action of minute vibratile cilia, assisted, according to Dutrochet, by the act of endosmosis. Sponges are propagated sometimes by ciliated gemmules, yellowish and oval, arising from the organic mucus, and carried out of the substance by the currents; they are mostly formed in the spring, and, after swimming freely about for some time, become fixed and grow. They also produce internal, unciliated, oviform bodies, resembling winter ova, which, when thrown out, swell, burst, and give issue to the locomotive germs within; they are said also to grow by division, or growth of detached portions of the parent body; they are believed to be nourished by minute algæ drawn within their pores. Some live in shallow, others in very deep water; scarce and small in cold latitudes, they increase in size and number toward the tropics, being most abundant in the Australian seas. The sponges of commerce are procured chiefly in the Mediterranean and the Bahama islands; they are obtained mostly by diving, to which persons are trained from childhood in the Greek islands; the adhesion is generally firm to the bottom, and the growth slow; the lime is removed by soaking in dilute muriatic acid, and they are then bleached and beaten for market. To bleach sponges, the finest and softest are selected, washed several times in water, and immersed in very dilute hydrochloric acid to dissolve out the calcareous matters; having been again washed, they are placed in another bath of dilute hydrochloric acid to which 6 per cent. of hyposulphite of soda dissolved in a little warm water has been added; the sponge is left in this bath 24 hours, or until it is bleached as white as snow. Smyrna is the chief place for the export of fine sponges. The coarse sponges used for horses and carriages, &c., are obtained chiefly from the Bahamas; when taken from the water they have a sickish, disagreeable odor, which soon becomes putrefactive and disgusting, like decomposing animal rather than vegetable matter; they are first buried in dry sand, and when decomposition has ceased are exposed in wire cages to the action of the tide for purification. According to Dr. Bowerbank, there are 24 genera of sponges on the shores of Great Britain. While *spongia* is the type of the corneous sponges, *thethys* (Ouv.) and *Grantia* (Flem.) are types of the silicious and calcareous sponges respectively. (See PROTOZOA.)

SPONTANEOUS COMBUSTION. See COMBUSTION, SPONTANEOUS.

SPONTINI, GAETANO, an Italian composer, born in Jesi, in the Papal States, Nov. 17, 1778, died in Majolati, near Jesi, Jan. 14, 1851. He studied under Padre Martini at Bologna, and at 18 became a pupil of the conservatory La Pietà at Naples. At 17 he composed his first opera, *I puntigli delle donne*, which met with a decided success; and 9 years later he

repaired to Paris, where were produced at the French opera his 8 most celebrated works, *La Vestale* (1807), *Fernand Cortès* (1809), and *Olympie* (1819). The first of these enjoyed the greatest reputation, and among the French Spontini was in his prime ranked as the equal of Rossini. Subsequently he was for a long time director of the opera at Berlin; but in the latter part of his life, passed partly in Italy and partly in Paris, he composed little.

SPOONBILL, the common name of the wading birds of the family *plataleida*, characterized by a much depressed bill, very broad, and dilated at the end in the shape of a rounded spoon. In the genus *platalea* (Linn.) the bill is long, straight, thin, slightly bent downward at the tip, the mandibles in close opposition and the edges not lamellar; nostrils basal and in the lateral groove; wings long, 21 quill the longest; tail short; legs longer than in the typical waders, tibia bare for nearly one half; tarsi not much longer than middle toe, covered with small hexagonal scales; toes webbed at the base, the outer longer than the inner, the middle not pectinated, and the hind one only partly resting on the ground; claws short and obtuse. There are about a half dozen species, found in all quarters of the globe, migrating to warm climates at the approach of winter; they frequent marshy inlets of the sea, and the borders of lakes and rivers, wading about in search of fish fry, worms, frogs, and aquatic insects; they can swim, and even dive, if necessary for escape; the nest is made either on trees or among rushes in swampy places, and composed of coarse sticks; the eggs are 2 to 4, whitish. The roseate spoonbill (*P. ajaja*, Linn.) is about 30 inches long, and 4½ feet in alar extent; the bill is 7 inches, and covered with a soft skin; the head is of moderate size, bare, the skin yellowish green; the neck long and slender, and the body compact and muscular. The prevailing color is rosy red, paler in front, and nearly white on the neck; lesser wing coverts, upper and lower tail coverts, and lower part of throat, bright carmine; tail feathers ochrey yellow; the young have the head feathered, the carmine tint wanting, and the tail rosy. It is found in the southern Atlantic and gulf states, and is so abundant in the breeding season at Indian river, Florida, that one person has been known to kill 60 in a day; it does not go above North Carolina, nor far from the sea; being very sensitive to cold, it is most abundant in the gulf states. They are essentially nocturnal, though they often feed by day when the tide suits; they are fond of the company of herons; they fly with the neck and legs extended, and rise rapidly to a great height; they alight easily on trees, and can walk on the large branches. The breeding time in the Florida keys begins in February, the young being out of the nest by April 1; the nest is usually in the top of a mangrove, coarsely made; the eggs are commonly 8, elongated, 2½ by 1½ inches, white, sprinkled all over with bright rufous spots, forming a ring near the large end; they breed and are commonly seen in flocks. The flesh is oily and poor eating; the beautiful feathers of the wing are made into fans in Florida, those from a single bird being worth at St. Augustine from \$1 to \$1.50. The European spoonbill (*P. leucorodia*, Linn.) is about the same size, of a white color, with reddish yellow patch on breast, pale yellow naked space around eyes and throat, and a yellowish white, long occipital crest; it is rare in England, but common in Holland and the southern portions of the continent and all over Africa. This curious genus has affinities with the cormorants and pelicans in the dilatable and bare gular membrane, with the curlews and herons in the alimentary canal, and with the sandpipers in the shape of the sternum; the trachea divides before entering the chest.—The shoveller duck (*spatula clypeata*, Boie) is also called spoonbill.

SPORADES (Gr., the scattered), the lesser islands of the Grecian archipelago surrounding the group of the Cyclades, divided into the northern, western, and eastern Sporades. The northern group includes the islands of Skiatho (anc. Sciathus), Skopelo (Scopelos), Skyro (Seyros), and Kilidromi (Halonesus); these lie off the N. E. coast of Negropont or Euboea, and belong to the kingdom of Greece. The western group, which also belongs to Greece, lies off the E. coast of Argolis, and includes Hydra (Hydra), Spezzia (Tiparenes), Poros (Sphæria), Ægina, and Koluri (Salamis). The eastern group belongs to Turkey, and lies off the S. W. coast of Anatolia; it includes Psara or Ipsara (Psyra), Scio (Chios), Samos, Nicaria (Icarus or Icaria), Patmos, Lero (Leros), Kalymna (Calymna), Stanko (Oos), Stampalia (Astypalæa), Anaphe, Skarpanto (Carpathus), and Kaso (Cassus). The Sporades of the ancients included only the eastern group, and this with the exception of the northernmost islands.

SPOTSWOOD, JOHN, a Scottish prelate, born in Edinburghshire in 1565, died in London, Nov. 26, 1689. He was graduated at the university of Glasgow at the age of 16, and at 20 was appointed to succeed his father in Calder kirk. At first strenuous in his opposition to episcopacy, even drawing up, or at least revising, according to Calderwood, in 1597, the defence for refusing to subscribe the bond demanded of the clergy by the king, it was not long before he began to side with the court party, and to favor a moderate episcopacy. In 1608 he was one of 5 clergymen selected by James I. to accompany him to London for his coronation, and while there was appointed to succeed Beaton as archbishop of Glasgow. He used henceforward his best exertions for the establishment of episcopacy in Scotland, and, though not given to violent measures, incurred much odium among the great body of the Scottish people. In 1609 he was appointed an extraordinary lord of session, but until 1610

was obliged to remain subject to the ordinary church courts. In 1610 he and two other Scottish bishops received episcopal ordination at the hands of English bishops, and soon after he was appointed head of one of the courts of high commission for trying offences against the church. He became primate of all Scotland in 1615, and the two courts of high commission were consolidated under his presidency. Under instructions from James I., though it is alleged contrary to his own wishes, he introduced the forms, services, appurtenances, and substantially the liturgy of the English church. In 1688 he placed the crown on the head of Charles I. as king of Scotland. He was appointed in 1685 lord high chancellor of Scotland. In consequence of the indignation aroused by the imposition of a book of canons and a new liturgy on the people, by order of the king, Spotswood in 1687 retired to Newcastle, and finally to London. He wrote a "History of the Church of Scotland, from the Year 208 to the Close of the Reign of James VI." (fol., London, 1655), and one or two smaller works.

SPOTTED FEVER (*typhus potchialis*, *typhus syncopalis*, or *typhus gravior*), an epidemic fever which prevailed in New England, New York, and Pennsylvania from 1807 to 1815. Medical writers now generally consider it as a form of malignant typhus, taking on, as epidemics of typhus are apt to do, certain peculiar characteristics, and possibly modified somewhat by the treatment adopted by some of the leading physicians. It is said to have appeared first in Medfield, Mass., in March, 1806, and a year later in the Connecticut valley and along the Hoosic and Green mountain ranges; it disappeared usually during the summer, but recurred for several years, with annually increasing violence, from January to April. It was most prevalent and fatal in 1812 and 1813. Its last appearance was at Berwick, Me., in 1815. The name spotted fever is inappropriate, if intended to indicate a fever distinct from the severe or malignant typhus, for the presence of both a red rash and of purple spots in that disease is one of its most marked symptoms; but the specific differences between this epidemic and ordinary typhus were said to be the time of year when it was most prevalent, spring instead of autumn; its avoidance of large towns, prevailing rather in thinly settled districts; its attacking more generally healthy and robust adults, rather than the weak, the young, or aged, and those of broken constitutions; and its stubborn resistance to the ordinary modes of treatment. It was very fatal, especially in the scattered population of villages, in which many heads of families were taken. In the latter part of its course it was very generally combined with local inflammations, particularly of the lungs or throat, but the symptoms of prostration which led to the name "sinking typhus," often applied to it, were even more strongly marked than in its earlier history.—The treatment of this epi-

demic led to a radical and bitter division in the medical profession. One party used stimulants very freely, avoiding bloodletting, and using from the commencement cinchona, brandy, opium, the tinctures of cinnamon, peppermint, lavender, &c., and these not so much with reference to the quantities given as the effects produced. Cathartics and emetics were used by this class of practitioners sparingly if at all, and cold water and other diluents sternly prohibited. In the use of this treatment they asserted that they were more successful than their opponents, and though the recoveries which took place were slow, they deemed them sure. The physicians who discarded this mode of treatment argued that the disease was at first a congestion, and that bleeding, either general or local, was necessary to relieve this, and if practised would be followed by less prostration and a more speedy recovery. This view gained prevalence after the appearance of the local inflammations in connection with the fever. The antiphlogistic physicians, as they were called, generally preferred local bleeding by leeches or cups to general; they administered calomel and mild cathartics and emetics, and after a time sustained the strength by the use of vegetable and mineral tonics. The mortality under either mode of treatment was very great, and neither had much cause to boast over the other. For many years subsequently the community as well as the physicians, especially in New England, were divided into two hostile parties, the stimulants and the antiphlogistics; and the controversy has hardly yet completely ceased.—The most noteworthy works on the epidemic were Miner and Tully's "Essays on Fevers and other Subjects" (1828); Miner, "Typhus Syncopalis" (1835); North and Strong on "Spotted Fever;" report of a committee of the Massachusetts medical society in its "Transactions," vol. ii.; Gallup on the "Epidemics of Vermont;" and Hale on the "Spotted Fever in Gardiner."

SPOTTSYLVANIA, an E. co. of Va., bounded N. E. by the Rappahannock and S. E. by the North Anna river, and drained by the Mattaponi; area, 400 sq. m.; pop. in 1860, 16,076, of whom 7,786 were slaves. The surface is hilly and the soil fertile. Granite and freestone are abundant. The productions in 1850 were 102,958 bushels of wheat, 265,753 of Indian corn, 47,487 of oats, 1,279 tons of hay, and 52,056 lbs. of butter. There were 8 newspaper offices, 20 churches, and 761 pupils attending schools. The Richmond and Fredericksburg railroad and the Rappahannock canal intersect the county. The value of real estate in 1856 was \$3,661,265, showing an increase of 28 per cent. since 1850. Capital, Spottsylvania Court House.

SPRAGUE, CHARLES, an American poet, born in Boston, Oct. 25, 1791. At the age of 18 he entered a mercantile house as clerk, and subsequently was taken into partnership by his

employers. In 1820 he became teller in the State bank; and in 1825, on the establishment of the Globe bank, he was appointed its cashier, an office which he still holds. In 1821 he became known as a poet by being the successful competitor for the prize offered for the best prologue at the opening of the Park theatre in New York. Similar successes were won by him in 1822, at the opening of the new Philadelphia theatre; in 1828, at the opening of the Salem theatre; in the same year, at the opening of another theatre in Philadelphia; and in 1830 at the opening of the Portsmouth theatre. In 1833 he obtained the prize offered for the best ode to be recited at the exhibition at the Boston theatre of a pageant in honor of Shakespeare; and in 1830 he pronounced an ode at the centennial celebration of the settlement of Boston. In 1829 he delivered a poem on "On-riosity," in the heroic measure, before the Phi Beta Kappa society in Cambridge, considered his best production. On the 4th of July, 1825, he pronounced the usual commemorative discourse before the citizens of Boston; and in 1837 he gave an address on intemperance. A new and revised edition of Mr. Sprague's writings was published in Boston in 1850.

SPRAGUE, WILLIAM BUEL, D.D., an American clergyman and author, born in Andover, Conn., Oct. 16, 1795. He was graduated at Yale college in 1815, and for nearly a year thereafter was a private tutor in the family of Major Lawrence Lewis, a nephew of Gen. Washington, who resided on a part of the original Mount Vernon plantation. He afterward studied for 3 years in the theological seminary at Princeton; and in Aug. 1819, he was ordained pastor of the Presbyterian church at West Springfield, Mass., as a colleague of the Rev. Joseph Lathrop, D.D. Here he continued 10 years, and on Aug. 26, 1829, was installed pastor of the second Presbyterian church in Albany, where he still remains. He visited Europe in 1828, and again in 1836. The degree of D.D. was conferred upon him by Columbia college in 1828, and by Harvard college in 1848. Dr. Sprague published in 1822 a volume of "Letters to a Daughter," which, being issued anonymously, was soon after published in Great Britain, and then republished in America as an English book. His subsequent works are: "Letters from Europe" (12mo., 1825); "Lectures to Young People" (1825); "Lectures on Revivals of Religion" (8vo., 1832); "Hints on Christian Intercourse" (1834); "Lectures illustrating the Contrast between true Christianity and various other Systems" (1837); "Memoir of Edward D. Griffin, D.D.," as an introduction to the volumes of sermons of that distinguished divine (1839); "Life of Timothy Dwight, D.D., President of Yale College," in Sparks's "American Biography" (1845); "Aids to Early Religion" (1847); "Words to a Young Man's Conscience" (1848); "Letters to Young Men, founded on the History of Joseph" (1854); "Visits to European Celebrities" (1855); and

"Annals of the American Pulpit," a collection of biographies of leading clergymen of all the denominations, which has reached 7 vols. 8vo. (1857-'61), and 2 more remain to be published. Of the books above named, nearly all have passed through several editions. He has written introductory essays to many works, contributed much to periodicals, and published also about 140 occasional sermons, addresses, &c.

SPRAT, a small fish of the herring family, and genus *harengula* (Val.). There are teeth on the jaws, tongue, palate, and pterygoid bones, but none on the vomer; the branchiostegal rays are 6 or 7. There are about 10 species, of which the most common is the English sprat (*H. sprattus*, Val.), called garvie in Scotland; it is 5 or 6 inches long, with the body proportionally deeper than in the herring, and the edge of the abdomen strongly serrated; the scales are large, round, and deciduous; the upper part of head and back dark blue, with green reflections, passing into silvery white on the gill covers, sides, and abdomen; dorsal and caudal dusky, other fins white. It is found on the coasts of Great Britain and Sweden, and in the English channel and North sea; it ascends the rivers in large shoals in November, after the herrings have disappeared. Though smaller and not commercially so important as the herring, it furnishes in the winter an abundant, cheap, and wholesome food, and is generally eaten fresh. The fishery is prosecuted by drift or stationary nets, and with most success in dark and foggy nights; it employs about 500 boats, which capture many thousand tons in some seasons; the excess is sold at 10 to 12 cents a bushel for manure, the farmers using about 40 bushels to an acre of land. The *blanquette* of the French coasts (*H. latulus*, Val.) is 3½ to 4 inches long, of a brilliant silvery white, tinged with greenish on the back; the flesh is dry, but sweet; they live a long time out of water. Several species in the West Indian seas are called sardines.

SPRAT, THOMAS, an English prelate and author, born in Tallaton, Devonshire, in 1686, died at Bromley, Kent, May 30, 1718. He was educated at Wadham college, Oxford, and after the restoration entered holy orders, and became chaplain first to the duke of Buckingham, and afterward to Charles II. He was one of the original fellows of the royal society. In 1688 he was made prebendary of Westminster, in 1690 canon of Windsor, in 1688 dean of Westminster, and in 1684 bishop of Rochester. He was clerk of the closet to James II., in 1685 was made dean of the chapel royal, and in 1686 one of the commissioners for ecclesiastical affairs. On the abdication of James, Sprat was one of those who, in the convention held on that occasion, proposed the appointment of a regent. An unsuccessful attempt was made in 1692 to implicate the bishop in a pretended plot to restore King James. He published "The Plague of Athens" and "The Death of Oliver Cromwell," poems (1659); "The His-

history of the Royal Society" (1677); "The History of the Rye House Plot" (1685); and a volume of sermons; and he edited Cowley's "Poems," with a life (1679).

SPRENGEL, KURT, a German physician and botanist, born at Boldekow, Pomerania, Aug. 8, 1766, died March 15, 1833. In 1784 he began at Halle the study of theology and medicine, but relinquished the former study, and took his medical degree in 1787. In 1789 he was appointed extraordinary professor of medicine in Halle, in 1795 ordinary professor in the same department, and in 1797 professor of botany, in which position he passed the remainder of his life. Sprengel's first work, *Anleitung zur Botanik für Frauenzimmer*, was published when he was but 14 years old; and his subsequent medical and botanical works procured for him honorary diplomas from upward of 70 learned societies, and invitations to fill various important professorships.

SPRENGER, ALOYS, a German orientalist, born at Nassereut, Tyrol, Sept. 8, 1813. After having studied medicine, natural sciences, and oriental languages at the university of Vienna, he went in 1836 to London, where he assisted the earl of Munster in his work on the "Military Science of the Mohammedan Nations." On the recommendation of Munster before his death, he received an appointment in the East India service, and in 1845 became president of the college of Delhi. In 1850 he was appointed examiner at the college of Fort William, interpreter of the government, and secretary of the Asiatic society of Bengal. He has published several editions of oriental writers, several works in the Urdu dialect, and a "Life of Mohammed" (vol. i., Allahabad, 1851). In 1859 the academy of inscriptions at Paris divided between Sprenger, Noeldeke, and Amari a prize for the best history of the Koran. He has engaged upon a new biography of Mohammed, in the German language, to be completed in 4 volumes, the first of which appeared in 1861.

SPRING, a current of water flowing out of the ground. Springs are produced from the water that falls upon the earth, and percolates through the soil, gathering in little rills, the "fountain heads of lakes and rivers underground." These find their way to the surface at lower levels, often at great distances from the localities that received the supplies from the atmosphere, and exhibit in their flow and the qualities of their waters a variety of interesting phenomena, some of which have already been considered in the articles *ARTESIAN WELLS*, *GEYSERS*, and *MINERAL WATERS*. From the times of earliest history, springs or wells of water have been objects of special regard. The wells in the vicinity of eastern towns and cities, and in the pasture lands, were resorted to by the women to draw water for domestic uses and for watering their flocks. The same custom there prevailed when Isaac met Rebekah at the well of Haran, and again when, 2,000 years afterward, it is alluded to

in the account of the woman of Samaria. Everywhere springs are suggestive of fertility, and even where they abound some among them are resorted to for the peculiar purity and refreshing coolness of their waters. Those of the same vicinity, supplied through different strata and from different sources, vary materially in their qualities. Some, forced up through beds of clean sand, are filtered of all impurities, though their source may be in dense swamps filled with decaying vegetable matters. Some, flowing to the surface through strata of limestone, though clear and apparently pure, contain so much calcareous matter in solution, that the water is characterized by that quality termed hardness; while others but a few yards distant, coming out through sandstone rocks, are eminently soft and pure. The phenomenon of hot and cold springs in close proximity has often been noticed since the time of Homer, who ascribed the source of the Scamander to two neighboring fountains of this character. A singular phenomenon relating to springs, observed by Prof. Brocklesby of Hartford, Conn., is their rising a little while before rain. Upon the summit of a high hill in the W. part of Rutland, Vt., is a spring which is almost always thus affected, sometimes two days before the rain appears; and another of similar character is said to exist in Concord, Mass. Prof. Brocklesby supposes the phenomenon is due to a diminished atmospheric pressure, which would also be indicated by a fall of the barometer. For the height of the spring at any time is determined by the relative force exerted by the atmosphere to keep the water down, and by the hydrostatic pressure to lift it up; and the channels and sources of supply of some springs may be so formed that the effect of diminished atmospheric pressure may thus be very sensibly indicated. The discharge of springs is often so uniform through periods of drought as well as of rain, that it is evident they must be connected with reservoirs beneath the surface too extensive to be affected by ordinary irregularities of supply; and there may well be such reservoirs of water when those of rock oil, as described in the article *PETROLEUM*, are sufficient to maintain continual supplies of this fluid for thousands of years. Such springs, called perennial, gush forth sometimes in large currents as well as in little rivulets, and rivers thus originate from the continuation of great subterranean currents. Instances of this kind are most common in limestone regions. It is this rock in which the great caves of the earth are usually found, and a common feature in these is a river large enough sometimes to be navigated by boats. In the Nicotack cave, Dade co., Ga., near the Tennessee river, there is said to be a waterfall 8 miles underground. As the rivers leave the caverns, and flow over the surface, they occasionally fall into other chasms and disappear, coming out again in great springs, it may be several miles off. Sometimes it happens that

the readiest outlet is in the bed of the ocean, and the fresh water is violently forced by its greater head up through the salt water, so that it may be collected at the surface almost or entirely unmixed. A spring of this kind in Boston harbor, now covered by Long wharf, supplies the shipping with water; another in the gulf of Spezia, a branch of the gulf of Genoa, rises in a powerful jet; and on the S. coast of Cuba, some distance from the shore, the fresh water springs burst upward with such violence that boats cannot safely approach the spot. Intermitting springs are those which flow for a certain period and then cease for a time, and so on alternately flowing and disappearing without regard to the supplies of rain. This is probably owing to the water collecting in a natural reservoir at an upper level, the outlet of which is a close channel through the rock curved upward so as to act like a siphon. When the water fills the reservoir and rises above the arch of the siphon, the flow commences, and continues until the discharge has carried the water down to the level of the shorter limb of the siphon; it then stops until the water has regained its former height. The younger Pliny in a letter to Licinius describes a spring of this character near the Larian lake, the modern lake of Como, which ebbs and flows regularly 3 times a day. A more celebrated one is the ancient pool of Siloam, which was observed by Dr. Robinson as still rising and falling at intervals in the manner described by Jerome and subsequent writers. From the inhabitants of the vicinity he learned that the flowing occurs at irregular intervals; sometimes 2 or 3 times a day, and sometimes, in summer, once in 2 or 3 days. The Geysers are intermitting hot springs; but the changes in their flow are due to other causes, as probably the sudden conversion of the waters into steam by coming in contact with beds of highly heated rock or lava, or the accumulation of large quantities of steam in the upper part of cavities until it can drive out the water beneath through the channels leading from the bottom to the surface. Hot springs are common in volcanic countries, in regions of extinct volcanoes, as that of Auvergne in central France, and in districts where the rock formations are traversed and displaced by long and deep lines of faults, as in central Virginia. In these localities the waters must penetrate far down to highly heated beds of rock, possibly ancient lava beds not yet cooled; or the depth may be so great that their high temperature may be owing to the general increase of heat observed in descending into the interior. (See CENTRAL HEAT.) Heated, and at the same time under great pressure, the waters possess powerful solvent properties, and thus they become charged with salts and gases by which the mineral springs are characterized. As the waters cool or evaporate, some portion of the solid matters held in solution is set free and deposited around the springs. Thus are produced

great beds of travertine, such as are observed in Tuscany and other parts of Italy—a spongy deposit of calcareous matter, which incrusts all substances it comes in contact with, and rapidly forms one class of petrifications. The thermal springs of Hierapolis in Asia Minor were particularly celebrated in ancient times; and it was stated of the transforming power of the waters, that if these were led about the vineyards and gardens the channels became long fences, each a single stone. At the present time there is to be seen a powerful hot spring at the place, and a cliff of calcareous rock formed from its deposits. The Geysers furnish examples of silicious deposits similarly produced. Cold springs as well as hot are often charged with ferruginous matters, derived from the decomposition of pyritous iron contained in the rocks over which the waters have flowed. The great ochreous deposits result from such springs, and the accumulations sometimes amount to important beds of iron ore, as described under BOG ORE. Springs charged with different mineral substances which give to them special importance are further noticed in the account of these minerals under their own names, as BORACIC ACID, GAS, PETROLEUM, and SALT.

SPRING, in astronomy, one of the 4 seasons of the year, commencing for the northern hemisphere at the time of the vernal equinox, or on March 21, and ending at the time of the summer solstice, or June 21. In the United States the spring is regarded as including the 3 months March, April, and May. (See SEASONS.)

SPRING, in mechanics, an elastic body, variously constructed and of different materials according to the purpose for which it is designed. The applications of springs are very numerous and for many totally different objects. Many are used, as in carriages, to relieve the jar caused by hard bodies coming suddenly in contact with each other; others as a moving power, acting through the tendency of a coiled metallic spring to unwind itself (see CLOCKS AND WATCHES), or by sudden release from a state of tension to communicate motion, as the bow to the arrow, the gun spring to the cock, the spring pole to the drill, and in many more such instances; others are employed as regulators to control the movements of wheel work, as seen in the hair springs of watches. All of the above act on the principle of resisting compression; others, by the amount of extension produced in a spring coiled around a central axis, are used as measurers of weight. (See BALANCE.)—In organic bodies springs are also a common feature, and serve some of the purposes for which they are introduced in mechanical structures. The cartilages in the joints are springs that prevent the ends of the bones from jarring upon each other. It is by the sudden release of a springy membrane in the structure of the flea, that this little animal is enabled to project itself instantaneously 200 times the height

of its own body; and in the vegetable kingdom springs are provided, sometimes round the outside and sometimes round the inside of the seed vessels, which finally burst these suddenly open, and scatter the seeds for the next crop.—Carriage springs contribute not merely to the comfort of the rider, but they lessen the force of draught by easing the load over the obstacles, and very materially increase the durability of the carriage itself. One of the early forms of these springs, introduced in the 17th century, consisted of two broad leather straps extending from an elevated framework on one axle to a similar frame on the other; upon these the body of the carriage was securely fastened. The antique 4-wheeled state carriages of Europe are mostly constructed on this plan; and a good evidence of its efficiency is the fact that many of the best stage coaches of the present time are thus supported. The principle was also in common use not long since in 2-wheeled gigs or chaises, and is still in the West Indian *volante*, points of support behind being provided by two long slender arms, connected by a cross bar at their extremities, to which bar the straps are secured. Swung upon the straps, which admit a limited lateral motion, with the advantage of the elasticity of the arms behind and of the shafts in front, the spring of these carriages is most perfect. An improvement was early introduced by making the frames that supported the straps elastic, by means of bands of steel curved over in the shape of the letter C, over the top of which the straps, secured at the bottom, were passed. The strength of these springs may be increased to any desired extent, by introducing several thicknesses of steel plates in the lower portion of the spring. Sometimes the framework which supports the C springs rests itself upon the form of elliptic springs known as under springs. Steel springs of various forms are now generally in use for carriages, being light and occupying little room. Those known as elliptic are steel plates or thin bars, so shaped that when two are put together they present an elliptical figure, and being secured together at the ends a spring is produced as pressure is brought to bear upon them to flatten the ellipse. They are bolted below upon the axle and above to the frame of the carriage by their central part, and are strengthened by additional thicknesses of steel in this portion. Very strong springs, for the heaviest wagons and railroad cars, are made of straight pieces of steel plates of gradually increasing lengths piled one upon another and fastened directly to the axle, or else over and across each end of it to the frame which rests upon the axles at these points. The frame of the carriage is secured to the ends of the longest and uppermost plate by eye bolts passing through these ends, which are turned over for their reception.—The varieties of steel springs for carriages are too numerous to be particularly named. Locomotives and railroad carriages demanded springs of unusual strength

and efficiency, and to act as near as possible with equal effect under heavy and light loads. These also have been devised of different forms and materials. Air, being the most elastic of all bodies, makes an excellent spring, the weight resting upon inverted hollow cylinders, set upon pistons fitting air-tight. In practice it has been found exceedingly difficult to prevent the escape of the air around the piston; and the following improvement has been devised for this purpose. The inverted cylinder, or rough cup, is provided with a very strong but flexible diaphragm or cover of several thicknesses of India rubber, stout canvas, and leather, covered on the inside with sugar house molasses. This rests upon a rounded head of wood, and is filled out with compressed air forced in by a small air pump, the pressure amounting it may be to 150 lbs. to the square inch. To prevent the air from passing through the pores of the cast iron pump, this is lined with tin. India rubber car springs are very extensively used. They are made of disks of any thickness, piled upon each other to any desired height, and contained in a cylindrical case, in the top of which fits a piston resting on the pile. It is obvious that between the frame to which the pistons are attached and the weight other springs may be introduced. Instead of India rubber disks others of steel are also used, saucer-shaped, and arranged in pairs upon each other, the pair consisting of two disks set face to face. The disks are made more durable and efficient by corrugating the metal. Another form is of flat disks of steel, less than $\frac{1}{8}$ of an inch thick, set between disks of cast iron of the same diameter, and made alternately with convex and concave surfaces. The tendency of the pressure applied to such a pile is to change the flat steel face into a slightly dishing form, which is resisted by the elasticity of the steel. Single disks operate when the load is light; the occasional introduction of two together in the pile provides for the same action with an increased load, and of three or more for still greater weights. Thus the same pile is very ingeniously made to furnish springs of different degrees of stiffness, which are brought into action only as the load upon them requires. A pile 6 inches high and of 5 inches diameter of outside case admits a motion of $1\frac{1}{2}$ inches before it is fully compressed. Springs thus designed for sustaining heavy bodies may be also applied to prevent their horizontal concussion, as of cars upon railroads, and also to relieve them from the sudden jerk which without springs they would receive in starting.—How it is that steel when tempered receives the high degree of elasticity that renders this metal so useful for springs is not understood. By grinding and polishing the property may be lost, and by hardening and tempering it is restored. It thus seems probable that the elasticity resides in the thin blue oxidized surface. The removal of the blue tint from a pendulum

spring by its immersion in weak acid was found by Mr. Dent to impair its elasticity, causing the chronometer to lose nearly a minute each hour; and a second and equal immersion scarcely caused any further loss. In stating this to the British association, he added that such springs get stronger in a minute degree during the first 2 or 3 years they are in use, from some atmospheric change; when they are coated with gold by the electrolyte process no such change is observable. Watch springs, as described by Holtzapffel, are hammered out of round steel wire, of suitable diameter, until they fill the gauge for width, which also insures equality of thickness. When the holes are punched in their ends and they are filed smooth on the edge, they are bound with wire in a loose open coil, and heated over a charcoal fire upon a perforated revolving plate. They are then hardened by dipping them in oil, and the oil is blazed off. The next process is grinding and polishing with emery and oil between lead blocks, which destroys the elasticity. A subsequent hammering on a very bright anvil restores this, "putting the nature into the spring." The coloring of orange or deep blue, which some consider merely ornamental, is imparted by moving the spring back and forth 2 or 3 inches at a time over a flat plate of iron or wood under which a little spirit lamp is kept burning. The spring is finally coiled by attaching it when cold to a small axis and causing this to revolve by means of its winch handle. Chronometer balance springs, of screw form, are shaped and tempered by winding them into the square thread of a screw of the right diameter and pitch. The two ends being fastened to the screw, the whole is carefully enveloped in platinum foil and tightly bound with wire. It is then heated in a piece of gun barrel closed at one end and plunged into oil, which hardens the spring almost without discoloring it. The outer covering is now taken off, and the spring is let down to the blue before it is released. The hair springs of common watches are frequently left soft; but the best are hardened in the coil upon the plain cylinder, and are then carried into the spiral form between the edge of a blunt knife and the thumb, as in curling up a narrow ribbon or paper. These springs are so delicate that it takes 3,200 of them to weigh an ounce; the soft ones are valued at 2s. 6d. each, and the hardened and tempered ones at 10s. 6d. Thus an ounce of metal, worth originally less than 2d., is made in the one case worth £400, in the other £1,600.

SPRING BALANCE. See **BALANCE.**

SPRING, SAMUEL, D.D., an American clergyman, born at Northbridge, Mass., Feb. 27, 1746, died in Newburyport, March 4, 1819. He was graduated at Princeton college in 1771, and in 1775, having been licensed to preach, became a chaplain in the continental army, and accompanied the expedition under Col. Arnold to Canada. At the close of 1776 he

left the army, and in 1777 was ordained pastor of a church in Newburyport, in which relation he continued till his death. He was a man of great influence and weight of character, and, as the leading minister of the Hopkinsian party, was active in promoting the union of the two parties in the Congregational church, effected by the establishment of the Andover theological seminary, and also in the organization of the American board of commissioners for foreign missions. He published about 25 miscellaneous discourses, and one or two small controversial works.—**GARDINER, D.D., LL.D.,** an American clergyman, son of the preceding, born at Newburyport, Mass., in Feb. 1786. He was graduated at Yale college in 1805, and after studying law a short time went to the island of Bermuda as a teacher, and remained there nearly two years, at the same time pursuing the study of law. After his return he was admitted to the bar, and practised more than a year, when he resolved to devote himself to the ministry. He studied about 8 months at the Andover seminary, and was ordained as pastor of the Brick church (Presbyterian) in New York, Aug. 10, 1810, in which office he still continues (1862). He has been elected successively president of Hamilton and Dartmouth colleges, but in both cases declined. Beside a large number of sermons and addresses in pamphlet form, and numerous contributions to periodicals, he has published "Essays on the Distinguishing Traits of Christian Character" (8vo., 1813); "Memoirs of the Rev. Samuel J. Mills" (8vo., 1820); "Fragments from the Study of a Pastor" (12mo., 1838); "Obligations of the World to the Bible" (12mo., 1844); "The Attraction of the Cross" (8vo., 1845); "The Bible not of Man" (12mo., 1847); "Discourses to Seamen" (12mo., 1847); "The Power of the Pulpit" (12mo., 1848); "Memoirs of Hannah L. Murray" (8vo., 1849); "The Mercy Seat" (8vo., 1849); "First Things" (2 vols. 8vo., 1851); "The Glory of Christ" (2 vols. 8vo., 1852); "Contrast between Good and Bad Men" (2 vols. 8vo., 1855); "Brick Church Memorial" (8vo., 1861).

SPRINGFIELD, a city and the shire town of Hampden co., Mass., situated on the E. bank of the Connecticut river, 98 m. W. by S. from Boston, and 138 m. N. N. E. from New York, in lat. 42° 6' 10" N., long. 72° 35' 12" W.; pop. in 1860, 15,199. The town is drained by Mill river, which furnishes water power for manufacturing establishments. The E. portion of the town, where the U. S. armory is situated, is considerably elevated, while the W. part is level. The city is well built, and has wide streets which are lined with trees. The city hall is a noble building in the Romanesque style, and, beside the city offices and library, has a large public hall which will accommodate comfortably an audience of over 2,500 persons. There are 12 churches in the city, viz.: 1 African, 1 Baptist, 4 Congregational, 1 Episcopal, 1 Roman Catholic, 1 Second Advent, 1 Swedenbor-

gian, 1 Unitarian, and 1 Universalist. The city library, formed in 1859, has rooms in the city hall, and numbers 8,000 volumes; there is a valuable scientific and historical museum in connection with it, and both are rapidly increasing. The schools of the city include 1 high, 17 grammar, 15 primary, and 6 mixed schools. There is one newspaper, issuing daily, weekly, and tri-weekly editions, and having a larger circulation than any other newspaper in New England out of Boston. The city has 5 banks, with an aggregate capital of \$1,200,000; 8 savings banks, with \$1,881,745.68 on deposit; 4 fire insurance companies, with an aggregate capital of \$650,000; and a mutual life insurance company, with \$400,000 capital. Hampden park, opened in 1857 for national horse shows, on the bank of the Connecticut, contains 60 acres, with a costly dike to protect it from the spring freshets. The Springfield cemetery contains about 40 acres, with a great variety of shade trees and fountains. Springfield is the focal point of 8 lines of railroad, which meet in one immense station house, each having extensive connections; these are the western railroad, to Albany, connecting at Worcester with the Boston and Worcester; the New Haven, Hartford, and Springfield; and the Connecticut river railroad.—The manufactures are important. The great national armory is now the only manufactory of small arms owned and worked by the United States government. The process of manufacturing the rifle musket, the principal arm now made, and which requires for its completion more than 500 distinct operations, is described in the article *GUN*, vol. viii. p. 572. In addition to the ample water power, a steam engine of 70 horse power has recently been introduced. Over 1,500 men are employed, the work is kept up night and day, and the production is nearly 12,000 complete guns per month, and is to be increased by additions of men and machinery till 200,000 stand of arms are produced annually. The workmen are all paid by the piece. The germ of the armory existed during the revolution, but it was not formally established till 1794. From that time till 1841 it was under civil superintendence, and the work was not satisfactory. In 1841 Major (now Brigadier-General) J. W. Ripley was appointed superintendent. In 1854 a change was again made to a civil superintendency, but Major Ripley's system was maintained. During the year 1861 a military superintendent, Major Dyer, was again appointed, and the vast increase of production consequent upon the war has been made without any deterioration in the quality of the arm. The weapon now made is of the model of 1855, and varies little from the Enfield musket. Maynard's primer has been discarded, and the nipple for percussion caps restored. The weight of the rifle musket is 9½ lbs. When not required for immediate use, the guns are stored in the great arsenal, 200 feet long by 70 wide and 8 stories high, which is capable of containing 100,000 stand of arms on

each floor. The armory grounds, which are extensive, are enclosed with an iron fence and beautifully laid out with trees, shrubbery, and flowers. New buildings, required by the exigencies of the time, and for which an appropriation of \$500,000 has been made, are soon to be erected. The manufacture of firearms is also carried on by several private firms. There is a large machine factory, making steam engines and boilers, steam saw mills, cotton presses, and coining and gun-making machinery; 2 extensive foundries for casting car and locomotive wheels, and various light and heavy work; a car manufactory, building baggage, freight, and passenger railroad cars to order, and also artillery carriages for the government; a gas company, furnishing the city; 2 sash, blind, and door manufactories; a steam saw and lumber dressing mill; an India rubber manufacturing company, making suspender and other elastic goods; a candy manufactory, a paint and chemical company, a woollen mill, several flouring mills, and two gold chain manufactories.—Springfield was made a city in 1852. It is divided into 8 wards, and is governed by a mayor elected annually, 8 aldermen, and 16 common councilmen. The fire department embraces 6 engine companies, 2 of which belong to the U. S. armory, but do duty wherever required.—Springfield was first settled in 1635 by emigrants from Roxbury, who on May 14 drew up and signed an agreement for self-government. The place was first named Agawam, the Indian name of a river of West Springfield, which with several adjacent towns was then included in its boundaries. In 1637 a church was formed, and in 1638 the settlers chose William Pynchon magistrate, and in April of the same year named the settlement Springfield (from the name of his residence in England) in compliment to him. Mr. Pynchon, who was an enterprising merchant as well as a theologian and author, returned to England in 1652; but his son John remained, and in 1662 erected the famous "Pynchon house," the first brick house in the Connecticut valley, and long a serviceable fortress against the assaults of the Indians. This venerable structure stood till 1831, and is represented on the city seal. In 1675, during King Philip's war, the Indians burned the settlement, destroying about 80 houses and 25 barns. In Jan. 1787, the armory, which then contained a considerable quantity of arms, was attacked by Daniel Shays and his party, during Shays's rebellion; but they were dispersed at the firing of the first cannon by the state troops. The growth of the town was slow till the opening of the western railroad in 1838, since which it has increased rapidly.

SPRINGFIELD, a city and the capital of Clarke co., Ohio, situated near the junction of Lagonda creek with Mad river, 43 m. W. from Columbus, and 84 m. N. from Cincinnati; pop. in 1860, 7,202. It is in the heart of one of the richest and most populous agricultural regions in the Union, and is well laid out and hand-

somely built. The public buildings are substantial structures, and there are many elegant private residences. It has great water power for manufacturing purposes, and there are numerous large flouring mills in and around the city. There are iron foundries, machine shops, 2 linseed oil mills, a woollen factory, a paper mill, and numerous other factories. Limestone is largely quarried and burned, producing lime of excellent quality. A number of important railroads centre here, viz.: the Springfield and Columbus; the Sandusky, Dayton, and Cincinnati; the Springfield and Delaware; the Little Miami; and the Columbus and Xenia. There are 1 daily, 1 tri-weekly, and 2 weekly newspapers, 3 banks, 16 churches, and 2 flourishing female seminaries. Wittenberg college (Lutheran) is situated here. A large trade is carried on in wheat, flour, Indian corn, and other produce, and many cattle and swine are exported by railroad to eastern markets.

SPRINGFIELD, a city and the capital of Illinois, and seat of justice of Sangamon co., 186 m. S. W. from Chicago, and 97 m. N. N. E. from St. Louis; pop. in 1860, 9,600. It is situated on a beautiful prairie, 4 m. S. of Sangamon river. Its streets are broad, intersect each other at right angles, and are tastefully adorned with shade trees. From the beauty of the place and its surroundings, it is termed the "Flower City." The state house is one of the finest buildings of the kind in the country, and the other public buildings are handsome and substantial structures. There are 5 newspapers, 4 banking houses, several steam flouring mills, foundries and machine shops, 12 or 14 churches, and 4 public and several private schools. It is the seat of the Illinois state university. It is on the line of the St. Louis, Alton, and Chicago, and the Toledo, Wabash, and Great Western railroads, and is the point of shipment for immense quantities of produce and great numbers of cattle and swine. The value of real and personal property in 1857 was \$4,451,907. Springfield was made the state capital in 1836, and was incorporated as a city in 1840.

SPRINGFIELD, the capital of Greene co., Mo., on the line of the S. W. branch of the Pacific railroad, 260 m. S. W. from St. Louis, and 180 S. S. W. from Jefferson City; pop. about 1,500. Its situation is high and healthy, and prior to the commencement of the war of secession it was the most important and flourishing town in S. W. Missouri. It has a city charter. During the war Springfield and its vicinity have been the scene of several important movements. Brig. Gen. Lyon, commanding a division of the federal forces, arrived at Springfield, Aug. 5, 1861. On the 8th a skirmish occurred at Dug creek; and on the 10th a battle was fought at David's and Wilson's creeks, the first 9 and the second 15 miles from Springfield, in which Gen. Lyon, with 8 divisions, commanded by Gen. Sigel, Major Sturgis, and himself, attacked the confederate force in greatly superior numbers under Gens. McCulloch and

Price; and after 6 hours' severe fighting, the federal troops remained in possession of the camp, but with the loss of Gen. Lyon and 228 killed, 721 wounded, and 291 taken prisoners on the federal side, and a still heavier loss on the side of the confederates. After the battle Gen. Sigel, taking the chief command, was obliged to fall back on Springfield and the next day to Rolla, to await reinforcements. Gen. Rains, of the confederate army, occupied Springfield with 4 regiments of cavalry on the evening of the 11th. On Oct. 25 Major Charles Zăgonyi, commander of Gen. Fremont's body guard, with 160 mounted troops of that guard, in advance of the main federal army, attacked the confederate force at Springfield and captured the town, while held by about 2,000 troops; his loss was 50 killed, wounded, and missing; the confederate loss was 60 killed. On Nov. 8, Maj. Gen. Hunter, appointed to supersede Fremont in command of the federal forces in the department of the West, arrived with his staff at Springfield, and on the 9th abandoned it with his army and returned north-eastward. On the 27th it was again occupied by the confederate forces, but again abandoned by them on the advance of the U. S. army under Gen. Curtis in Feb. 1862, by which they were driven into Arkansas and defeated at Sugar creek and Pea Ridge, Benton co., March 6, 7, and 8.

SPRUCE. See FIR.

SPURGEON, CHARLES HADDON, an English preacher, born at Kelvedon, Essex, June 19, 1834. His father and grandfather were preachers in the Independent denomination. At the age of 16 he commenced teaching as an usher at Newmarket, and subsequently at Cambridge. Not long after going to Cambridge he connected himself with a "Lay Preachers' Association" there, and went out almost every evening to some one of the villages adjacent, to conduct religious meetings. Soon he commenced preaching, and before he was 18 became pastor of a small Baptist congregation at Waterbeach, one of these villages. In 1854 he was called to the New Park street Baptist chapel in Southwark, London; and his preaching soon drew such crowds that the congregation removed first to Exeter hall, and then to Surrey music hall, the largest public room in London. In 1861 a new chapel of great size was completed for his congregation. Mr. Spurgeon for several years preached an average of nearly a sermon a day, and has beside visited the continent several times, corresponded regularly with an American newspaper, written several books, and superintended the education of a number of young men for the ministry. His sermons have nearly from the first been printed weekly, and 6 volumes have been published collectively.

SPURZHEIM, JOHN GASPAR, M.D., a Prussian philosopher, and one of the founders of phrenology, born at Longwisch, Prussia, Dec. 31, 1776, died in Boston, Mass., Nov. 10, 1832. He was educated at the university of Treves, and studied divinity and philosophy. When

Treves was invaded by the French army, Spurzheim with the other students fled to Vienna, where he became acquainted with Dr. Gall, and soon after was employed as his assistant, making dissections for him. From 1805 to 1808 Spurzheim and Gall visited the principal cities of Europe, lecturing and demonstrating their views by dissections of the brain. In 1808 they presented a joint memoir to the French institute on the anatomy of the brain, explaining their discoveries; and the committee to whom it was referred reported on the whole favorably. The two phrenologists then commenced the preparation of their great work on the "Anatomy and Physiology of the Nervous System in general, and of the Brain in particular," of which Spurzheim contributed to the first two volumes. In 1818 they separated, and thenceforward prosecuted their labors independently of each other. Spurzheim, after taking his medical degree at Vienna, went to England, and delivered his first course of lectures in London, and about the same time published "Physiognomy in connection with Phrenology," and "Observations on Insanity." These works were violently attacked by Dr. John Gordon in the "Edinburgh Review," and Dr. Spurzheim at once visited Edinburgh, and in the presence of more than 500 medical students, the pupils of Dr. Gordon, demonstrated the fibrous character of the brain, which the latter had denied. He went to Paris in 1817, and lectured for several years, publishing also works on phrenology, insanity, and education. His lectures being prohibited in 1825, he went again to England, in 1831 returned to Paris, and in the summer of 1832 visited the United States. Having delivered several lectures in Boston, he was seized with a fatal fever from over exertion about 2 months after his arrival. Dr. Spurzheim's principal works, beside those already mentioned, are: "Anatomy of the Brain" (8vo., London and Boston, 1831-'2); "Phrenology, or Doctrine of the Mind" (8vo., London and New York); "Sketch of the Natural Laws of Man" (London and Boston).

SPY, as defined by Bouvier, "one who goes into a place for the purpose of ascertaining the best way of doing an injury there. The term is mostly applied to an enemy who comes into the camp for the purpose of ascertaining its situation in order to make an attack upon it." The punishment inflicted on a detected spy is death. In all time it has been an acknowledged right of nations at war with each other to avail themselves of the service of spies or secret emissaries in carrying on their hostile operations. Before entering Canaan the Hebrew lawgiver twice sent spies to examine the land and the condition of the people. Grotius and Vattel lay down numerous principles in regard to their employment. It is admitted by all writers on international law that there is something revolting to the mind of an honorable man in performing the service of a spy, and therefore a commander has not a right to

compel one of his soldiers or officers to undertake it. He may urge him to it by pecuniary or other motives, but if he still refuses he may not compel him. The spy, in his assumed character, is justified in obtaining what information he can concerning the condition and purposes of the enemy, but it is wrong for him to resort to assassination or poisoning. "He may weaken the enemy," says Vattel, "by all possible means which do not affect the common safety of human society." Writers on international law also hold that a commander is justifiable in tempting or soliciting, by bribes or otherwise, an enemy's subjects to betray him, or act as spies, though they admit that such a course is hardly compatible with strict rectitude. They insist, however, that it is perfectly right to accept the offers of a traitor. The commander does not seduce him, and it is right that he should take advantage of his crime, though he may detest him for committing it.—In the history of the border wars in the western states and territories of North America, this word is frequently used to denote a species of scouts or rangers, usually backwoodsmen or hunters, who marched in the advance or on the flanks of an army, to act as guides, and to watch, as the name implies, the motions of the enemy—especially to seek and detect the ambuscades of the Indians. They were not spies in the odious military sense of that term. The service was honorable, and was equivalent to that of light troops in regular armies. This use of the word is peculiar to American history.

SQUADRON, in military science, a body of cavalry comprising 2 companies or troops, and averaging from 150 to 200 men. A detachment of ships of war employed on a particular expedition is also called a squadron.

SQUARE (Lat. *quadratum*), in geometry, a figure formed of 4 equal sides meeting each other at right angles. The term appears to have been originally applied to the corners of figures alone, and in the oldest English work on geometry (Recorde's "Ground of Arts"), the word quadrate (four-sided) is added to it when it is used to designate a square figure. It is common, even at the present time, to find it used in a similar sense, as when applied to the tool called the carpenter's T square, a rule of two limbs united at a right angle, and used for drawing right angles. The word is applied also to angles, though not to right angles, in calling a triangular file 8-square.—Square measure presents the superficial areas of surfaces in square units, as inches, feet, miles, &c.—In arithmetic, the square is a number consisting of another number multiplied by itself; and this use of the word evidently has reference to the geometrical figure, the area of which is equal to the number of units forming one of its sides multiplied by itself. The number thus multiplied is called the square root, and the method of discovering it in algebraic and arithmetical formulas is known as the extraction of the square root.

SQUASH. See GOWN.

SQUASH BUG, a well known hemipterous insect, the *corvus tristis* (De Geer). It is about $\frac{1}{2}$ of an inch long, with a triangular head; the general color is ochre yellow, rendered dusky above by numerous black dots; the sharp edges of the abdomen project beyond the closed wing covers; on the back of the head, behind the eyes, are 2 glassy raised eyelets. They appear by the last of June or beginning of July, when the squash vines have put out a few leaves, pair, and soon begin to lay their eggs; they conceal themselves by day, and in the evening fasten their eggs in little patches on the under side of the leaves by a gummy substance; the eggs are soon hatched, and the young, pale ashy and with large antennæ, at first live together in swarms; they resemble the adults except in the absence or rudimentary condition of the wings and their covers. They are hatched in successive broods during summer, pass through their last change, and attain their full size in September and October, when they leave the plants and conceal themselves in crevices, passing the winter and spring in a torpid state. The loss of sap from the punctures of these insects causes the leaves to become brown, dry, and wrinkled, when they are deserted for fresh ones. When irritated, and particularly when crushed, they give out a strong, nauseous odor. It is best to destroy them when few in number and before they have laid their eggs, or to crush the latter before the vines have begun to spread. Whatever promotes the vigorous growth of the plants renders them less liable to suffer from these bugs. The *C. marginatus* (Fabr.) of Europe is of an obscure brown, of similar habits, and emits a strong odor of apples.

SQUID, a cephalopodous mollusk, of the *debranchiate* order, tribe *decapoda*, family *teuthidæ*, and genus *loligo* (Lam.). The body is elongated, tapering behind, with a pair of terminal fins; branchiæ 2; arms 8, with 2 rows of pedunculated suckers, and 2 tentacles; the internal shell, or *gladius*, is reduced to a horny quill-shaped plate, with 2 lateral expansions; the ink bag is well developed, and its secretion jet black. They are good swimmers, all marine, and never leave the water; they can creep head down on the cephalic disk; the ova are enclosed in long, gelatinous, cylindrical sheaths, called sea grapes, and may be nearly 40,000 in number; the sight is good, and the movements rapid; they are used as food by man, as on the coasts of Greece. They are sometimes called calamaries, from the internal pen-like bone and ink bag, and the general cylindrical form like an ancient escriptoire. The common squid of the New England coast, the *L. illecebrosa* (Le-seur), is from 6 to 12 inches long; the colors vary rapidly, with the will of the animal, from yellowish white to bluish, violet, brown, red, and orange, in spots or general tint. They swim rapidly backward by dilating and contracting the sac-like body, and forward by the terminal

fin; they devour numbers of small fish and crustaceans, and in turn are eaten by larger fishes, and used as bait by cod fishers. Descriptions and figures of this and other American species may be found in the "Journal of the Academy of Sciences of Philadelphia" (vol. ii. p. 86, 1821). In the old world, squids are found from Norway to New Zealand; the *L. vulgaris* (Lam.), common about the shores of Great Britain, and used in Cornwall as a bait for cod, attains a length of 1 to 1 $\frac{1}{2}$ feet. The flying squids (*omastrephes*, D'Orb.), and the hook squid (*onychoteuthis* and *enoptoteuthis*, D'Orb.), have been alluded to under MOLLUSCA.

SQUIER, EPHRAIM GEORGE, an American author and archæologist, born in Bethlehem, Albany co., N. Y., June 17, 1821. Having for some time taught school and studied engineering, he went to Albany in 1840 and became connected with the press, and in 1841-'2 was assistant editor of the "New York State Mechanic," a politico-scientific journal, and identified with the movements of the mechanics for a reform in the system of state prison labor. In 1843 he became editor of the "Hartford (Conn.) Daily Journal," supporting the election of Henry Clay to the presidency, and in 1844 removed to Chillicothe, Ohio, to assume the editorship of the "Scioto Gazette." While filling this position and serving one term as clerk of the lower branch of the Ohio legislature, he made an extensive survey, in conjunction with E. H. Davis, M.D., of the ancient monuments of the Mississippi valley, and prepared a work on the subject which was published in 1848 as the first volume (4to.) of the "Smithsonian Contributions to Knowledge." In the autumn of 1848 he made an exploration of the aboriginal monuments of the state of New York, which was published by the Smithsonian institution in 1849, and also at Buffalo, N. Y., in 1852 (8vo.). In March, 1849, he was appointed by President Taylor chargé d'affaires to Guatemala, with extraordinary powers to the other Central American states. His despatches, subsequently published by order of congress in 2 volumes, related not only to political matters, but to the geography, topography, climate, and resources of the country, and particularly to the projected interoceanic canal. On the death of Gen. Taylor he returned to New York, and in 1851 visited Europe, residing there a year, receiving the medal of the geographical society of France, and being made a member of the royal society of literature, fellow of the societies of antiquaries of England, France, and Denmark, &c. Returning to the United States in 1853, he conceived the plan of an interoceanic railway through the republic of Honduras, made with a corps of engineers a preliminary survey of the route, negotiated the requisite concessions from the government of Honduras, and organized at New York a company for carrying forward the work. He subsequently visited Europe, where he secured the coöperation of many English and French capi-

talists, and special guaranties for the road from the English and French governments. As an incident in these negotiations, he drew up the treaty between Great Britain and Honduras for the retrocession of the Bay islands, the principles of which, adopted by the former, opened the way for the adjustment of all her disputes with the Central American states. The final survey of the proposed railway was also conducted under his direction. Beside those above mentioned, Mr. Squier has published the following works, most of which have been translated into German, French, or Spanish: "Nicaragua, its People, Scenery, Ancient Monuments, and proposed Inter-oceanic Canal" (2 vols. 8vo., New York and London, 1852); "The Serpent Symbol, or Worship of the Reciprocal Principles of Nature in America" (8vo., New York, 1852); "Notes on Central America," &c. (1854); "Waikna, or Adventures on the Mosquito Shore," under the *nom de plume* of Samuel A. Bard (12mo., 1855); "Question Anglo-Américaine," &c. (8vo., Paris, 1856); "The States of Central America," &c. (8vo., New York, 1857); "Report of the Survey of the Honduras Inter-oceanic Railway" (4to., London, 1859); "Translation, with Notes, of the Letter of Don Diego de Palacio (1571) to the Crown of Spain on the Provinces of Guatemala, San Salvador, &c." (New York, 1860); "Monograph of Authors who have written on the Aboriginal Languages of Central America" (1861); and "Tropical Fibres and their Economic Extraction" (1861). He has also contributed numerous articles to this cyclopædia and the "Encyclopædia Britannica," to the "Transactions" of the American ethnological society and of numerous scientific societies of Europe, and to many American and European periodicals and public journals.

SQUILL, the bulb of plants of the genus *scilla* or *squilla*, of which the *S. maritima*, or sea onion, furnishes the medicine called squill. The plant is perennial, and grows on the coast of the Mediterranean. The bulb is pear-shaped, from 8 to 6 inches in diameter, and consists of fleshy scales, closely laid over each other, and covered by thin, dry, external scales, which are sometimes red and sometimes white. The juice is viscid and very acrid, but its acrimony partially disappears, without loss of medicinal power, when the bulb is dried. For this purpose it is cut into thin slices, and exposed to artificial or solar heat. It is exported in oblong pieces of a white or dull yellowish white color, possessing a feeble odor, and bitter, nauseous, and acrid taste. Analyzed by Tilloy of Dijon, it was found to contain a very acrid and poisonous resinoid substance; a very bitter principle, previously recognized by Vogel and called *scillitin*; a fatty matter; citrate of lime; and mucilage and sugar. About $\frac{1}{4}$ of a grain of the first named substance was found sufficient to kill a dog.—Squill yields its medicinal properties to water, alcohol, and vinegar, and is also used in substance in the form of pill. Its

effects are expectorant, diuretic, and, in large doses, emetic and purgative. It is used in combination with tartar emetic or ipecacuanha to stimulate the vessels of the lungs; and in dropsical diseases it is much employed to increase the secretory action of the kidneys.

SQUILL (*equilla*, Fabr.), a genus of crustaceans of the division *stomatopoda*, so called from having the feet placed around the mouth. The body is elongated and generally slender, the head distinct from the thorax, the carapace leaving uncovered $\frac{1}{4}$ of the thoracic rings, and the abdomen terminating in a wide caudal fin of several plates adapted for swimming. The antennæ of the 1st segment of the body are long, ending in 8 many-jointed filaments, cannot be bent under the head, and are inserted below the eyes near the median line; the antennæ of the 2d segment are shorter, more external, having at the base a large ciliated plate, and terminate in a single many-jointed filament; the eyes are at the end of movable appendages. The mouth is toward the posterior 3d of the carapace, and has an upper and under lip, a pair of mandibles, and 2 pairs of jaw feet arranged around it; the 8d pair of feet are prehensile, strong, bent back on themselves, serrated and spined, and used very much like the 1st pair of feet in the scuthsayer (*mantis*); the next 8 pairs are directed forward, applied against the buccal apparatus, and inserted close together, with a wide, rounded, ciliated plate at the end; the last 3 thoracic limbs are slender, with styliform process and ciliated, the segments to which they are attached resembling those of the abdomen. Most of the rings of the body are complete, very nearly equal, and movable on each other; the carapace is nearly quadrilateral, longitudinally divided by 2 more or less distinct grooves; the 1st 5 abdominal rings have large false feet, to the posterior part of the base of which are attached the respiratory organs in the shape of floating, ramified, and fringed gills, which are kept constantly in motion. The heart has the form of a long vessel, a little dilated anteriorly, extending almost the length of the abdomen and thorax, sending off lateral branches to each ring; the venous sinuses in which the blood is collected before going to the gills are very large; the stomach advances far into the head. There are many species, all marine, most abundant in the tropics, but some coming as far N. as the English channel; they are usually met with far from shore and in deep water; they swim rapidly, striking the water with their powerful tail; they are voracious and carnivorous. The best known species is the *S. mantis* (Fabr.), 6 or 7 inches long, of a pale yellowish gray color, found in the Mediterranean; the carapace is widened and elongated posteriorly, with the anterior angles spiny; the prehensile feet have 6 teeth; the abdomen has 8 longitudinal rows of crests above; the caudal plates are spiny.

SQUINTING (Lat. *strabismus*), a deformity resulting from a want of parallelism between

the visual axes of the eyes. Except in cases where it is caused by paralysis, spasmodic or hydropical affections, or irritation of the brain, it is not a disease, and is accompanied with no pain or lack of visual power. Ophthalmic surgeons notice 3 degrees of squinting: 1, where there is but a slight convergence or divergence from the normal axis, such as is ordinarily called a "cast of the eye;" 2, where the inclination is strongly marked, but less than half the cornea is thrown under the eyelid or within the orbit, which is the most frequent variety; 3, where the cornea is nearly or quite thrown under the eyelid or within the orbit, common among those who are born blind, but rare in the case of those who can see. The surgeons also distinguish it according to the departure from the normal axis, such as convergent, where the pupil is drawn toward the nose; divergent, where it is drawn toward the outer corner of the eye; ascendent, where it is drawn upward; and descendent, where it is drawn downward. Of these, the convergent form is by far the most frequent, and next in order the divergent and ascendent. The descendent is the rarest of all. Squinting may also be double or single as one or both eyes are affected; it may be congenital, i. e., existing from birth, or accidental, occurring from accident or improper treatment of the eye; the former is rare. It may be also continuous, or rarely intermittent. The cause of ordinary strabismus or squinting is the lack of equal power in the muscles which move the eye. (See EYE.)—The treatment prior to 1839 consisted in attempting by various methods to strengthen the weaker muscles, bandaging the normal eye, and compelling the constant use of the other; or by the use of goggles, spectacles, &c., in which all except the centre was opaque. In 1838 Stromeyer described the operation of dividing one of the *recti* muscles, but without having tried it on the living subject. In 1839 Dieffenbach, an eminent surgeon of Berlin, performed it successfully, and was followed by many English and French surgeons. The operation has now become very common, though the best surgeons admit that there are 3 classes of cases in which it should not be performed, viz.: those in which the position of the eye is fixed, those which result from the paralysis of the antagonist muscle, and those occurring in infants before dentition. The operation is not difficult nor particularly dangerous, and in about $\frac{1}{4}$ of the cases proves partially or entirely successful. There are two methods of performing it, the ordinary or that of Dieffenbach, where the conjunctiva is divided and the muscle to be severed is laid bare, and the subconjunctival method, where the conjunctiva is only punctured by the instrument which divides the muscle beneath it. The former is generally preferred. The operation was introduced in the United States in 1840 by Dr. Detnold.

SQUIRE. See **ESQUIRE**.

SQUIRREL, the popular name of the rodents of the family *sciuridae*, which is very numerous

in species, and widely spread over the world, except in Australia. These well known, active, and familiar animals are characterized by a broad head, the frontal bone being dilated into a post-orbital process; the muzzle wide, from the development of the frontal and nasal bones; eyes large and prominent, ears moderate, and whiskers long; the hind feet 5-toed, the fore feet 4-toed, with a wart-like thumb, all the fingers and toes with compressed and curved claws; the fur is generally soft, especially in the northern species, and the tail is long, hairy, expanded laterally in the arboreal genera, and shorter and bushy in the terrestrial, and in both carried gracefully over the back; the upper lip is cleft, the cæcum large, clavicles perfect, enabling them to use the fore limbs to convey food to the mouth, and the tibia and fibula distinct; some have a membrane extended between the fore and hind limbs, as has been noticed under **FLYING SQUIRREL**. The incisors are $\frac{1}{2}$, smooth in front, brown or orange, the lower compressed and sharp; molars $\frac{1}{2}$ - $\frac{1}{2}$, rooted, tuberculate, with projecting transverse striæ enamelled continuously, the anterior upper one the smallest and sometimes deciduous. The food is chiefly vegetable, though some American species are known to suck eggs and destroy young birds. The family is very abundant in North America, nearly $\frac{1}{4}$ of all the species being found here; the prairie dogs and prairie squirrels are peculiar to this continent, as well as most of the flying squirrels. (See **FLYING SQUIRREL**, **PRAIRIE DOG**, and **PRAIRIE SQUIRREL**.)—The genus *sciurus* (Linn.) is the type of those of the family which live in trees; the species of the United States are hard to determine from the tendency to variation in color (red, gray, and black being the predominating tints), and the diminution in size in the southern states. Mr. Baird states it as a general rule that, when a squirrel has the fur of the throat or belly annulated, it is a variety of some species which normally has the under parts uniformly white or reddish to the roots, or the latter plumbeous. The bones of the red-bellied squirrels are generally red, and of the white-bellied white. The largest of the North American species is the fox squirrel of the southern states (*S. vulpinus*, Gmel.), about 2 $\frac{1}{2}$ feet long, of which the tail is 15 inches; the head is rather slender and pointed, and the tail rather cylindrical; the upper molars are permanently 4. The color varies from a gray above and white below, through various shades of rusty, to uniform shining black; the fur is coarse and harsh, and the ears short; the ears and nose are white in all its varieties. It is found from North Carolina through the S. Atlantic and gulf states to Brazos river in Texas. The gray variety is the *S. capistratus* (Bosc), and the black the *S. niger* (Linn.) and the black squirrel of Oatesby. It prefers elevated and open pine ridges where there are occasional oak, hickory, and nut trees; the nest for

the winter and breeding seasons is made in a hollow tree, and in summer in the forks between the branches. The young are born in March and April, being fed by the parents for 4 or 5 weeks. The food consists of acorns, nuts, fruit of the pine cones, green corn in the summer, buds and roots in spring, and whatever it can get in the winter, as it does not appear to lay up any winter stores, or to resort to any hoards previously buried in the ground. When alarmed, it makes for a hollow tree; it is a swift runner, defends itself boldly, and is very tenacious of life; it is generally seen toward the middle of the day; it is easily domesticated, but is less active in the cage than the smaller species; its flesh is frequently eaten. The cat squirrel (*S. cinerea*, Linn.), the fox squirrel of the middle states, is 25 or 26 inches long, of which the tail is about 14; the head is very broad, the muzzle short and cat-like, the body thick and heavy, and the tail large and flattened; the color varies from light gray tinged with rusty above and white below to grizzly above and black below; it is never pure black; the ears are low and broad, and never white; the hair is less coarse and stiff than in the preceding species. It is found chiefly in the middle states, rarely in southern New England; it is rather a slow climber, and of inactive habits; it becomes very fat in autumn, when its flesh is excellent, bringing in the New York market 8 times the price of that of the common gray squirrel. The species called fox squirrel in the western and southwestern states (*S. ludovicianus*, Harlan) has a very full and broad tail; it is rusty gray above and ferruginous below. The common gray squirrel (*S. carolinensis*, Gmel. and *S. migratorius*, Aud. and Bach.) is about 22 inches long, of which the tail is 12; the upper molars are permanently 5. The general color is gray above and white below, with a yellowish brown wash on the back and sides; the region behind the ears has usually a white woolly tuft; there is a black variety, the *S. niger* of Godman. The ears are very high, narrow, and acute, the tail flattened, feet large, claws strong, thumb a rudimentary callosity; the palms naked, and soles mostly so in summer; whiskers longer than the head. It is found extensively over the United States, being much the smallest at the south; this difference in size and some modifications of the habits, according to climate and locality, have led authors to make two species, with the names given above, which Mr. Baird unites in one. It is a very active animal and an excellent climber, in the south preferring the low cypress swamps; it is often met with late in the evening and on moonlight nights, when it falls a victim to owls, foxes, wild cats, &c., as well as to hawks and snakes by day; the young are 4 to 6, born in May or June. They are easily domesticated, and gentle in confinement, and are often kept as pets in wheel cages; they do not lay up any great amount of winter stores,

being partially torpid at this season and requiring but little food; they are very fond of nuts, and of green corn and young wheat, on which last account wars of extermination are often waged against them, whole villages turning out on an appointed day to hunt them, killing great numbers. At irregular periods they sometimes collect in large troops in the north-west, migrating eastward, crossing rivers and mountains, and committing great destruction in the fields in their course. Of late years many of this species have been domesticated in the public parks of northern cities; though pets of children and loungers, they drive away the birds by destroying their eggs and young. The California gray squirrel (*S. fessor*, Peale) is as large as the fox squirrel, but more slender; it is grizzled bluish gray and black above and white below; tail black, white on the exterior and finely grizzled below; back of ears chestnut. It represents on the west coast the gray squirrel of the east. It runs very swiftly on the ground, not readily taking to trees when pursued; like the other squirrels, it has a kind of bark; the food consists principally of nuts, which it sticks in holes of pine trees bored by woodpeckers, resembling pegs placed in the wood. The red or Hudson's bay squirrel (*S. Hudsonius*, Pall.) has a stout body 7 or 8 inches long, and the tail rather less, narrow and flat; ears moderate, broad, tufted at the tip. The color above and on the sides is a mixed black and grayish rusty, with a broad wash of bright ferruginous down the back and the upper surface of the tail; dull white below; tail rusty on the margin, within which is a narrow black band; there is often a black line on the flanks, separating the colors of the sides and belly; the soles are hairy or naked according to the season. It is found from high northern latitudes to the Mississippi, and throughout the northern and middle Atlantic states in elevated regions. It is active, graceful, fearless of man, cleanly, and industrious in laying up a winter supply of food; it sometimes makes its nest in outbuildings; it is very lively all winter, eating its supply of nuts, and the seeds of pines and firs; in cold climates it burrows in the ground at the foot of some large coniferous tree. It is called chickaree from its loud chattering note; its flesh is tender and well flavored; it is less gentle and easily tamed than the gray squirrel. The common European squirrel (*S. vulgaris*, Linn.), much resembling the last, is about 14 inches long, of which the tail is about $\frac{1}{2}$; the color is reddish, chestnut brown on the back, white below, becoming gray in winter in the north, and yielding then the much prized fur called minever; the ears are tufted, and the hair on the tail is directed to the two sides. It is found throughout Europe and N. Asia; it feeds in summer on buds and shoots, especially the young cones of the pine, and in winter on a supply of nuts which it gathers in autumn and hides in some hollow tree. It is an excellent climber, and makes a nest of moss, leaves, and fibres very

neatly interwoven, in a hole or fork of a tree, and well concealed; a pair live together, frequenting the same tree for many years; the young are born in June, and remain with their parents till the following spring; they remain torpid in the very coldest days. The largest of the squirrels is the Malabar squirrel (*S. maximus*, Schreb.), 83 inches long, as large as a cat; it is black above, the sides and top of head chestnut, and lower parts pale yellow; it lives in palm trees, feeding on the milk and meat of the cocoanut.—The ground squirrels (*tamias*, Illig.) have cheek pouches extending to the occiput and opening internally; the tail is shorter than the body, the feet large with well developed claws adapted for digging, and the anterior basal plate of the zygoma perforated by a nearly circular foramen; the permanent upper molars are 4, the tail is not bushy, and there are 3 to 5 longitudinal stripes on the back. They burrow in the ground near the roots of trees, and their nest is well supplied with winter food; they form a connecting link between the squirrels proper and the spermophiles or prairie squirrels. The common American ground, striped, or cheeping squirrel, chipmunk, or hicksee, has the body 5 to 6 inches long, and the tail about 4½; on the back and sides are 5 longitudinal black stripes, not extending over the rump, the outer 2 on each side separated only by a white line; rump pale chestnut, and the upper parts generally finely grizzled yellowish gray and brown; lids and under parts white, and a downy white spot behind the ears; it is the *T. striatus* (Linn.). It varies but little, and is found from Canada and Lake Superior to Virginia and Missouri. It is lively, playful, and busy, and may be said to occupy among mammals the place of the wren among birds; it is very commonly seen running along the fences and walls in New England, cheeping like a young chicken, the cheek pouches distended with nuts or seeds, occasionally stopping and standing upright, watching against enemies, and disappearing in some hole at the least alarm. The young are born in May, 4 or 5 at a birth. They are hardly injurious to the farmer, not disturbing the grain before it is ripe, and only gleaning after the harvest; they feed chiefly on nuts, wheat, buckwheat, Indian corn, cherry stones, and grass seeds, with which their winter burrows are plentifully supplied. They are easily captured in traps, but are not readily tamed, and are rarely seen in cages; their worst enemy is the weasel, which pursues them into their burrows. The Missouri striped squirrel (*T. quadrivittatus*, Wagn.) is smaller, with the intervals between the stripes all grayish white; beneath it is dirty grayish white, and the general color is more ferruginous; it most resembles the *T. Pallasi* (Baird) of N. Asia and Siberia.

SQUIRREL CORN. See DIOENTRA.

SQUIRREL, FLYING. See FLYING SQUIRREL.

STAAL, MARGUERITE JEANNE COORDIER DE LUXAY, baroness de, a French writer, born in

Paris in 1698, died June 15, 1750. She was educated by charity at a convent in Rouen; in 1710 she became chambermaid to the duchess de Maine at Sceaux, but soon attracted attention by her superior knowledge and abilities, having among her friends Fontenelle, Marivaux, Montesquieu, and Mme. du Deffand. Being an active agent in the conspiracy of Cellamare, she was arrested, and was for two years confined in the Bastille; she then resumed her situation at Sceaux, and afterward married an old Swiss officer, the baron de Staal, who was appointed commander of a company in the duke of Maine's guards, with the rank of major-general. She left personal *Mémoires*, and letters that are still sought for on account of their terseness and wit. The former have been frequently reprinted separately or in historical collections; the latter are found in her *Œuvres complètes* (2 vols. 8vo., Paris, 1891).

STABAT MATER, the first words of a celebrated Latin hymn of the church, generally sung on the festival of the seven sorrows of the Virgin, and during Holy Week. It was probably composed by Jacobus de Benedictis, commonly called Jacopone, a Franciscan friar, who flourished in the latter half of the 13th century; but the words have received several changes. It has been set to music by many of the most eminent composers, including Palestrina, Pergolesi, Astorga, Haydn, Neukomm, and Rossini. The composition of Pergolesi (for two voices with an accompaniment), commenced upon his deathbed and finished by another hand, is the most celebrated, although that of Rossini is the most popular in the concert room.

STADIUM (Gr. *stadion*), originally a Grecian course for foot races at the places where games were celebrated, and sometimes in the gymnasia of cities where there were no games. The most celebrated stadia were those at Olympia, Delphi, Thebes, Epidaurus, and the Panathenaic at Athens. The stadium was an oblong area terminated at one end by a straight line, and at the other by a semicircle, with ranges of seats rising above one another in steps around the circumference. The length of the stadium at Olympia was 600 Grecian feet, equal to 606 feet 9 inches English; and from continual reference to it as a comparison, this length became used throughout Greece as the standard of measurement for itinerary distances, and was subsequently adopted by the Romans, chiefly for nautical and astronomical measurement. From discrepancies in the distances recorded by Greek writers, it has been thought that different stadia were referred to; but such discrepancies probably arose from the distances in question being computed, and not measured. Thus, a certain number of stadia were allowed for a day's journey; one man would make the same journey in less time than another, and would record the distance as so many stadia less in proportion to this difference.

STADTHOLDER (Dutch, *stadhouder*, a city or state holder or keeper, a governor; Ger.

Stadthaller), the title given by certain of the United Provinces of the Netherlands to William of Orange, who thereupon became the chief magistrate or president of those provinces and commander-in-chief of their forces. In 1587 Maurice, his 2d son, was appointed stadtholder of the United Provinces, and the dignity continued in the house of Orange, with occasional intermissions during which the states-general governed without a stadtholder, until 1747, when William IV., of a collateral branch of the Orange family, was declared hereditary stadtholder. After the restoration of the Orange family in 1814, the title was exchanged for that of king, which is also hereditary.

STAËL-HOLSTEIN, ANNE MARIE LOUISE GERMAINE (NECKER), baroness de, a French authoress, born in Paris, April 22, 1766, died there, July 14, 1817. She was the only child of Necker, the wealthy Swiss banker and minister of finance to Louis XVI. Her early education, under the direction of her mother, was severe and systematic, and almost from infancy she was thrown into the society of the many distinguished persons who frequented the *salon* of Mme. Necker, whence she acquired the art of brilliant and thoughtful conversation, for which she was always remarkable. At the age of 20 she was married, through her mother's management, to the baron de Staël-Holstein, the Swedish minister to the French court—an alliance which, while it gave her rank and position in society, had little in the wishes or sympathies of the parties to recommend it. In 1788 appeared her first work of importance, *Lettres sur les ouvrages et le caractère de J. J. Rousseau*, which, notwithstanding an unreasonable admiration for her subject, contains a masterly exposition of some of the sophisms of the *Nouvelle Héloïse*. With the outbreak of the French revolution her imagination kindled at the prospect of political and social reform which seemed about to dawn upon the country. But gradually, as popular violence and fanaticism gained a place in the public councils, she employed her pen boldly in denunciation of the factious course of parties, and in defence of the royal family and others, whom she now considered the oppressed instead of the oppressors. Compelled during the reign of terror to leave Paris, she resided first at her father's estate of Coppet, Switzerland, and afterward at Richmond, England, in society with Talleyrand, the count de Narbonne, and other distinguished emigrants, some of whose lives she had saved at the commencement of that period. She returned after the establishment of the directory, and until the usurpation of supreme power by Napoleon made her saloons the rallying point of those who favored a compromise between monarchy and the principles of 1789, and looked with distrust upon the designs of Bonaparte. The latter, having attempted in vain to secure her support, finally ordered her to leave Paris, and not to remain within 40 leagues of the city.

Passionately fond of the social attractions of the capital, and of the literary and fashionable celebrity which she there enjoyed, she obeyed with extreme reluctance the command of the first consul, and retired to Coppet, where she prepared for the press her novel *Delphine* (1802). She then travelled to Italy, her impressions of which country are recorded in *Corinne* (Paris, 1807), a work defective in plot and dramatic interest, but full of eloquent remarks on scenery, manners, and art, and unsurpassed as a poetical description of a poetical country. It has been repeatedly translated into every European language, and is still the work on which her literary reputation mainly rests. A subsequent residence in Germany, where she was intimate with Goethe, the Schlegels, and other eminent men, afforded the materials for her *De l'Allemagne*, which was in 1810 seized in Paris by the police, after 10,000 copies had been printed, notwithstanding it had passed the test of the French censorship. The emperor's hostility probably prompted this arbitrary act, although the authoress was informed by the minister, Savary, in answer to her remonstrance, that the publication had been stopped because "the work was not French." Being closely watched at her residence in Coppet after this, she succeeded in 1812 in making her escape to England, whither she was obliged to proceed by a tedious overland journey through Germany, Russia, and Sweden, the seaports being closely watched by the French. *De l'Allemagne* appeared in London in 1818. After the abdication of Napoleon she returned to Paris, and resumed her old position as a literary celebrity and a leader of public opinion. She passed through the Hundred Days unmolested by Napoleon, but after the second restoration retired to Switzerland, and seemed to have lost her interest in active politics. She travelled again to Italy in the hope of restoring her health, and, returning to Paris, busied herself with preparing for the press her last work, *Considérations sur la révolution Française*, published posthumously by her son in 1819 (8 vols. 8vo.). It is written with commendable temperance and impartiality, and is remarkable for graphic portraits of public men of the revolutionary period. Her friend Benjamin Constant observed that if she had painted individuals more frequently and more in detail, her work might have ranked lower as a literary composition, but would have gained in interest. She also wrote *De l'influence des passions* (1796); *De la littérature considérée dans ses rapports avec les institutions sociales* (1800); *Réflexions sur le suicide*; *Essai sur les flotions*; *Vie politique de Necker*; *Dix années d'exil*, an autobiographical narrative; and a variety of minor productions, some of which appeared posthumously. She was buried in the family tomb at Coppet, which bears the inscription: *Hic tandem quiescit, quæ nunquam quievit*. The baron de Staël-Holstein had died in 1802; and by the dispositions of her will it appeared

that for several years previous to her death she had been secretly espoused to a young officer, M. de Rocca, by whom she had a son, the concealment of the marriage being due to her reluctance to part with a name so long identified with her literary fame. She left two children by her first husband, the baron Auguste de Staël, and Albertine, duchess de Broglie, both eminent for virtues and piety. The former edited the complete works of his mother in 18 vols. (Paris, 1820-'21), and a memoir of her was published by Mme. Necker de Saussure (8vo., Paris, 1821). In 1862 was published her inedited correspondence with the grand duchess Louisa of Saxe-Weimar, from 1800 to 1817 (8vo., London).

STAFF, in military science, a corps of officers attached to a commander for the purpose of assisting him in carrying his designs into execution. The staff of an army may be distinguished under 3 heads: 1, the general staff, consisting of adjutants general and assistant adjutants general, aides-de-camp, inspectors general and assistant inspectors general, &c., whose duties, apart from the communication of the orders of the general-in-chief, embrace the whole range of the service, whence their title of general staff officers; 2, the staff corps, whose duties are confined to distinct branches of the service, as the engineers, topographical engineers, ordnance, quartermasters', subsistence, medical, and pay departments; 3, the regimental staff, which includes regimental officers and certain non-commissioned officers, whose duties assimilate to those of adjutants general, quartermasters, and commissaries. The employment of a military staff, as a regular branch of the service, dates from the reign of Louis XIV.; but in European armies it cannot be said to have constituted a permanent corps until upward of a century later. The wars of the French revolution and of Napoleon were conducted by the French army without such a corps, the officers employed on the staff being detailed from the various arms of the service for that purpose, and returning afterward to their own regiments. The French have now however a special school for the instruction of staff officers, who form a permanent corps, and the same may be said of the principal military establishments of Europe. A permanent general staff is however discountenanced by some military authorities, who favor a system which admits of supernumerary general and regimental officers selected temporarily for staff duties by commanders of troops. Such a system has always prevailed in the army of the United States. "The leading qualifications," says Napoleon, "which should distinguish an officer selected for the head of the staff are: to know the country thoroughly; to be able to conduct a reconnaissance with skill; to superintend the transmission of orders properly; to lay down the most complicated movements intelligibly, but in few words and with simplicity."

STAFFA, a small uninhabited island of Scotland, one of the inner Hebrides, Argyleshire, 6 to 8 m. W. from Mull. It is of irregular elliptical form, about $1\frac{1}{2}$ m. in circumference. Its surface is an uneven plateau, elevated from 50 to 144 feet above the sea, the upper rock being composed of a shapeless basaltic mass, with occasional small columns, resting upon a columnar basalt, hard, grayish black, compact, and of perfectly regular forms, which has for its foundation a conglomerate trap or tufa. This columnar basalt, strongly resembling architectural designs, is indented with numerous caves, of which the most remarkable is that known as Fingal's cave. It opens with a noble gateway, of an absolute height from the rocky floor to the top of the entablature of 117 feet 6 inches, and from the surface of the water at mean tide to the top of the arch inside of 66 feet, and nearly 54 feet in breadth. The sea at all times flows into the cave, and has at the entrance a mean depth of 18 feet, but at the inner terminus shoals to 9 feet. The action of the waves has broken a number of the columns at the entrance. Sir Joseph Banks measured the depth of the cave from the entrance to the terminus, and found it 371 feet 6 inches, but it is now reckoned as only 227 feet. For the whole distance the sides of the cave are supported by massive columns of basalt, usually pentagonal or hexagonal, but sometimes with 7 or 9 sides, and very rarely triangular or rhomboidal, 2, 3, or 4 feet in diameter; from the roof depend, for the whole length of the cave, clusters of columns, whitened with calcareous stalactites and sparkling with innumerable crystals. The whole cave is lighted from without, so that the farthest extremity is plainly distinguished, and the air is said to be dry and wholesome. The basaltic columns, which form the façade of the entire island, are found in all positions, erect, oblique, horizontal, and curved or bent. The other principal caves are the Boat cave, the Cormorant cave, so called from the number of these birds which visit it, and the Clam Shell cave, which derives its name from the peculiar form in which the basaltic columns are inclined, giving it the appearance of a shell of the genus *pecten*; it is 80 feet high, 16 to 18 feet broad, and 180 feet long.

STAFFORD, an E. co. of Virginia, bordering on the Potomac, bounded S. W. by the Rappahannock, and drained by Aquia and other creeks; area, 835 sq. m.; pop. in 1860, 8,555, of whom 3,314 were slaves. The surface is hilly, and the soil along the Potomac is moderately fertile. The productions in 1860 were 178,651 bushels of Indian corn, 58,928 of wheat, 38,750 of oats, and 2,018 tons of hay. There were 2 cotton factories, 5 grist mills, 2 saw mills, 12 churches, and 245 pupils attending public schools. Gold has been discovered, and granite and freestone of an excellent quality are found. The Richmond and Fredericksburg railroad intersects the county. The value of real estate in 1866 was \$1,695,768, showing an

increase of 82 per cent. since 1850. Capital, Stafford Court House.

STAFFORD, HENRY, duke of Buckingham. See BUCKINGHAM, DUKES OF.

STAFFORD, WILLIAM HOWARD, viscount, an English statesman, born Nov. 30, 1612, executed on Tower hill, Dec. 29, 1680. He was the 2d son of Thomas, 20th earl of Arundel, the well known collector of the Arundelian marbles; and upon the death without issue of his brother-in-law Henry, 4th Baron Stafford, he succeeded in having the dignity conferred upon himself in right of his wife, who was at the same time created Baroness Stafford. In Nov. 1640, a few months later, he was created Viscount Stafford. He was brought up in the Roman Catholic faith, and adhered during the civil wars to the royal cause; but after the restoration, conceiving that he had not been rewarded according to his deserts, he was frequently found in opposition to the court, although he appears never to have played an important part as a legislator. He was, however, of sufficient prominence to be singled out by Titus Oates, the contriver of the "popish plot," as one of his chief victims. On Oct. 23, 1678, Oates deposed before the house of commons that upon the subversion of the kingdom by the Jesuits, Lord Stafford was to have the appointment of paymaster of the army; and on the 30th the accused nobleman was committed to the tower, with other Catholic peers against whom similar charges had been preferred. After lying two years in prison, he was brought to trial on a charge of high treason before his peers on Nov. 30, 1680, his 69th birthday. During a trial of 7 days he defended himself with an ability for which no one had given him credit; pointing out with such skill the weakness of Oates's evidence, that Evelyn, who was present, thought "such a man's testimony should not be taken against the life of a dog." But, as Dugdale and Tuberville, the other witnesses for the government, swore positively that Stafford had incited them to assassinate the king, a verdict of guilty was pronounced by a vote of 55 to 31. He was executed 8 weeks afterward; and such was the revolution in popular feeling which set in subsequent to his conviction, that, although he had been assailed by invective on the day of his trial, when he protested his innocence on the scaffold the spectators cried: "We believe you, my lord. God bless you, my lord." His eldest son was created earl of Stafford, which title expired with the 4th earl in 1762; and in 1825 (the attainder of Lord Stafford having been reversed in the previous year) his descendant Sir George William Jerningham succeeded to the barony of Stafford.

STAFFORDSHIRE, an inland and nearly central county of England, bounded by the counties of Chester, Derby, Leicester, Warwick, Worcester, and Salop; area, 1,250 sq. m.; pop. in 1861, 746,584. The principal towns are Stafford, the capital, Lichfield, Wal-

sall, Wolverhampton, Dudley, Tamworth, Burton-upon-Trent, Uttoxeter, Cheadle, Hanley, Burslem, and Newcastle-under-Lyme. The chief river is the Trent, which traverses the county in a N. W. direction, and has several considerable tributaries. Much of the surface consists of moorlands, elevated in some places 1,000 feet above the level of the sea, running in ridges separated by valleys sloping toward the Trent; the land in the valley of the Trent is good. Staffordshire is an important manufacturing county, and coal, iron, copper, and lead mines are worked extensively. The leading manufactures are iron, hardware, and earthenware, of which last it is the chief seat in England, and which gives name to a division of the county called the Potteries. There is perhaps no article of ironmongery or hardware which is not produced in Staffordshire. The pottery works established by Josiah Wedgwood, and still carried on by his descendants, are in this county. The ale breweries of Burton-on-Trent are very extensive and celebrated. Staffordshire is connected with the surrounding counties by a perfect network of roads, canals, and railways. There are some remains of Roman antiquities. The county sends 4 members to parliament, beside 18 for the boroughs.

STAG, the common name of the red deer of Europe (*ceruus elaphus*, Linn.) and its congeners. It is about 4 feet high at the shoulders, and of a general reddish brown color, tinged with grayish in the winter; on the rump is a pale spot extending a little above the tail; there is a blackish dorsal line, and on each side often a row of pale fulvous spots; the hair is brittle, and in old animals forms a kind of mane on the neck; the tail is moderate, the tear bag well developed, suborbital pit large, and the hoofs narrow, triangular, and compressed. The antlers are large and rounded, with an anterior basal and a median anterior snag, and the apex divided into 2 or more branches according to age; they are peculiar to the males, shed in the spring, and reproduced, sometimes to a weight of 24 lbs., by August. (For family characters see DEER.) It is a strong, swift, and vigilant animal, with a very acute sense of smell; it was formerly found in herds in the forests of the mountainous regions of temperate Europe, but is now rare except in the least inhabited parts, like the highlands of Scotland, where stag hunting is still a favorite sport with the privileged few. This in old times constituted the noble art of *veneris*, as distinguished from the more plebeian chase of the fallow deer and other species which resort to the plains more than the woods. Gestation continues 8 months; the young or calf is dropped in May, and is yellowish with white spots; the male is called a stag or hart, and the female a hind, the terms buck, doe, and fawn belonging properly to the fallow deer (*dama vulgaris*, Gesn.); the venison is coarser than that of the fallow deer. It has been found

fossil, with bones of the elephant and other pachyderms, in the Kirkdale cavern, the peat bogs of Ireland, and similar recent formations. It is represented in North America by the larger *wapiti* (*C. Canadensis*, Erzl.). (See WAPITI.) Other stags in the old world are the Barbary (*C. Barbatus*, Benn.), of N. Africa, of a dark brown color with back of haunches and obscure spots white; and the Nepal (*C. Wallichii*, Ouv.), brown, with a large white spot on the rump. Others are found in India and Japan.

STAG BEETLE, the common name of the family *Lucanidae*, of the lamellicorn pentamerous coleoptera, of which the type is the genus *Lucanus* (Linn.). Many of the species are of considerable size, and have received their name from the large and powerful mandibles with which the males are furnished. The stag beetle of Europe (*L. cervus*, Linn.) is 2 inches long, exclusive of the mandibles, and is the largest and most formidable of the British beetles; the color is black, with brown elytra; the head is wider than the body; the mandibles corneous, arched, with 8 large and several smaller teeth, and used as instruments of offence; antennae bent, pectinated, and 10-jointed, tibiae dentated along outer edge, and the tarsi ending in 2 hooks. They live in the trunks of trees by day, flying abroad at night, often into houses, where their sharp and stag-like horns cause no little alarm; the females are smaller, with narrower head and much shorter mandibles. They are also called horn beetles and flying bulls. According to De Geer, they feed principally on the sweet juice spread over the leaves of the oak and exuding on the bark, which they obtain by means of the brushes of the under jaws; they are said to seize caterpillars and soft-bodied insects, and to suck their juices; they are very strong, and can pinch the finger pretty hard, but do not use their mandibles in this way unless provoked, and their punctures are not poisonous; they live only a short time in the perfect state, perishing soon after laying their eggs in the crevices of bark near the roots of trees. The larvae are large and fleshy grubs with very thick body, arched, 13-ringed, and having a brown scaly head armed with 2 strong jaws with which they gnaw wood, reducing it to a coarse powder, and often doing much damage by boring into the trunks and roots of oaks and beeches; there are 6 scaly feet, attached to the first 3 rings; they are said to be 6 years in coming to their growth, and by some are regarded as the *coccus* of the Romans, a worm-like grub, according to Pliny, obtained from the oak and considered delicious food, but not coveted by modern epicures. The largest of the New England species is the *L. capreolus* (Linn.), usually called horn bug; it is about 1½ inches long, without the mandibles, the latter being sickle-shaped and toothed; the color mahogany brown, smooth and polished. They appear in July and August. The larvae are 8 inches long when full grown, straw-colored,

with yellow head, brown jaws, and 9 stigmata; they live in the trunks and roots of apple trees, willows, and oaks, and are sometimes injurious.

STAGNELIUS, ERIK JOHAN, a Swedish poet, born in the island of Oland, Oct. 14, 1798, died April 8, 1828. He was the son of a parish priest, afterward made bishop of Calmar, and received his education at the universities of Lund and Upsal. In 1815 he became a clerk in the Swedish office for ecclesiastical affairs, which position he held until his death. He died prematurely from excessive drinking. His poetical writings, including many in manuscript, were edited in 1824 by his friend Hammar-sköld in 8 vols., and comprise epic or narrative poems, dramas, lyrics, ballads, and miscellaneous minor pieces. His reputation has greatly increased since his death, and he is now ranked among the Swedish classics. His entire works have been translated into German, and specimens of his poems are given in Howitt's "Scandinavian Literature."

STAHL, GEORGE ERNST, a German chemist and physiologist, born in Anspach, Oct. 21, 1660, died in Berlin, May 14, 1784. He studied medicine at Jena, and became a lecturer there in 1684, professor of medicine, anatomy, and chemistry at Halle in 1694, and royal physician at Berlin in 1716. Professing as a pietist a disdain for all learning, he was yet the author of two theories prominent in the history of science. In his *Theoria Medica Vera* (Halle, 1707; new ed. by Choulant, 3 vols., Leipzig, 1831-'8; translated into German by Ideler, 8 vols., Berlin, 1832-'3) he supposed the existence of an *anima* or immaterial principle resident in the body, creating its organization, and governing all its processes with reference to the final purpose of preserving life. Every corporeal movement, he said, is the product of a spiritual order. He invented also the phlogistic theory, which prevailed till the time of Lavoisier, in development and defence of which he published *Zymotechnia Fundamental* (1697), *Experimenta et Observationes Chemica* (1781), and numerous dissertations.

STAHL, JULIUS FRIEDRICH, a German statesman and author, born in Munich, Jan. 16, 1802, died at Brückenau, near Kissingen, Aug. 10, 1861. The name of his parents, who were Jews, was Schlesinger, but he adopted the name Stahl when in 1819 he was baptized into the Protestant church. He studied law, was appointed in 1827 *Privatdocent* in the faculty of law at Munich, in 1832 extraordinary professor at Erlangen, and in the same year ordinary professor at Würzburg. In 1840 he accepted a call to the university of Berlin. In 1848 he founded with Bethmann-Hollweg the German church diet, of which he was vice-president until 1859, when a disagreement between the evangelical (low church) and the high Lutheran parties, of which latter he was the leader, led him to resign. In 1854 the king appointed him syndic of the crown, and a life member of the *Herrenhaus* (house of lords).

He was also appointed in 1852 a member of the supreme ecclesiastical council of the Prussian state church, which position he retained until 1858, when he resigned. In politics he opposed with great vigor and talent the spread of democratic principles. His most important work is *Philosophie des Rechts* (2 vols., Heidelberg, 1830-'37), in which he develops his famous theory of a "Christian state," which, according to him, is to aid the church by the secular arm in extending the dominion of Christianity, and in realizing its mission upon earth. In his work *Die Kirchenverfassung*, &c. (Erlangen, 1840), he declared himself in favor of an episcopal form of church government. In 1855 he had a controversy with Chevalier Bunsen, which, on account of the talent displayed on both sides, attracted general attention in literary circles. His last great work was *Die Lutherische Kirche und die Union* (Berlin, 1859).

STAHR, ADOLF WILHELM THEODOR, a German author, born in Prenzlau, Oct. 22, 1805. He was educated at Halle, and taught there till in 1836 he was invited to Oldenburg as professor in the gymnasium. He was chiefly occupied with the history and criticism of Aristotelianism, and published works thereon. An Italian journey furnished the subjects of *Ein Jahr in Italien* (3 vols., Oldenburg, 1847-'50; 2d ed., 1853), and of a historical romance entitled *Die Republikaner in Neapel* (3 vols., Berlin, 1849), characterized by a German critic as a "poetical lava of rustic, martial, and revolutionary scenes." He has also written other æsthetic and historical works. He married the authoress Fanny Lewald in 1854, and settled in Berlin.

STAIR, LORD. See DALRYMPLE.

STALACTITE (Gr. *σταλαξ*, to drop, to drip), and STALAGMITE (Gr. *σταλαγμα*, dripping, dropping), concretions of limestone formed by the water that percolates through fissures in the roofs of caves, carrying carbonate of lime in solution, which is left behind as the water evaporates. The collections thus formed on the roof itself and extending downward from it like icicles are called stalactites; those produced by the drippings upon the floor, and which rise in the form of mounds toward the roof, are called stalagmites. It is often the case that the two meet and form pillars, and sometimes broad sheets when the dripping follows a fissure in the roof or seams of stratification. In parts of Weyer's cave in Virginia the stalactites may thus be seen in parallel rows starting along the lines that mark the divisions between the steeply inclined strata in the roof; and in certain places lines of sheets are produced which reach from the roof to the floor. Some of them are so thin as to be translucent, and when struck produce a ringing sound. The cave of Adelsberg in Carniola is famous for the variety of its stalactitic forms, and among them are some remarkable examples of this character. The stalactites are seen hanging in

thin, transparent white sheets like linen, and one in particular is called the "curtain" from the striking resemblance in its flexures to the folds of a loose pendent sheet. Most of the grotesque figures in caves that give to these their chief interest, and suggest innumerable strange resemblances, are due to the varying forms of the groups of stalactites. In one place the pillars stand like trees in a grove; in another they suggest long colonnades and verandahs adorned with Gothic tracery; again they hang over the edge of a precipitous wall, resembling falling waters arrested in their course and turned into stone; and with every advancing step they present new and strange varieties. They are white and translucent like alabaster when the limestone that supplies their material is pure and white; but if this contain impurities, these are also taken along and deposited with the carbonate of lime. Thus are produced the various colors frequently seen in stalactites, and the concentric veins around their central axis which are brought to view in exposing a cross section by fracture. The common shapes of small stalactites are more like those of icicles, but in the interior the former are usually hollow for a foot or more from the upper end. This results from the water before it falls first evaporating around the outer edge of the drop or collection of drops, and thus causing the deposit of a ring of stony matter. Down the outer side of this more water gathers, continually adding new rings below, the cavity gradually contracting and finally terminating in a point. The upper portion gains in size by the partial evaporation of the water that flows down it, and thus the bluntness of the cone is increased. In places where the wind sweeps through the caves the regularity of the deposit is disturbed.

STALLBAUM, JOHANN GOTTFRIED, a German scholar and educator, born at Zaasch, Sept. 25, 1798. He was educated under Beck and Hermann at Leipsic, where he has been a teacher since 1820, and extraordinary professor in the university since 1840. He has published a highly esteemed critical edition of Plato (12 vols., Leipsic, 1821-'5), has edited several of the dialogues separately, and is the author of the introductions and annotations to Plato in the *Bibliotheca Græca* (9 vols., Gotha, 1827 *et seq.*). He has also edited Ruddiman's *Institutiones Grammaticæ Latinæ* (2 vols., 1823), Eustathius (5 vols., Leipsic, 1825-'30), and Terence (6 vols., 1830-'31); and he has written several treatises on education.

STAMEN, an essential organ in the inflorescence of phænogamous plants. The stamen consists normally of the filament and the anther, and where the corolla is present the stamens are situated immediately within it. Morphologically the stamen is a modified leaf, the filament being the midrib or petiole and the anther the blade or lamina. The anther is a closed receptacle secreting within itself a multitude of globules or grains of dust known

as the pollen (see *POLLEN*), and which are employed in the fecundation of the ovary. The stamen is subject to many modifications, and is reducible in its simplest form to mere pollen masses, as occurs in certain natural orders.

STAMFORD, a township and village of Fairfield co., Conn., lying near the mouth of Mill river, 40 m. S. W. from New Haven, and 86 m. N. E. from New York; pop. in 1860, 7,185. The New York and New Haven railroad traverses the village and the S. part of the township. There is a canal 180 rods long, 80 feet wide, and 7 feet deep, from the village to the bay, between Greenwich and Shippan points. The township is drained by Mill and Mianus rivers. It has considerable coasting trade, and large manufactories of iron ware, wire, boots and shoes, dye stuffs, coal oil, carriages, woolen and clothing. It is a favorite residence, especially in summer, of merchants and others engaged in business in New York. The village has a bank, a savings bank, a weekly newspaper, and 7 churches.

STAMMERING, a term generally applied to all kinds of defective utterance; a more exact use of language would, however, restrict it to the organic or symptomatic defects, in distinction from stuttering, which is properly an idiopathic or functional difficulty. Both stammering and stuttering may nevertheless be treated under the common title. The causes which lead to stammering are usually, though not always, organic; harelip, cleft palate, elongation of the uvula, enlargement of the tonsils, a deficiency or unusual position of the teeth, tumors of the tongue or cavity of the mouth, and inflammation or ulceration of the parotid glands, are the most frequent of these causes. Where the defect results from functional disturbance, its principal causes are general debility, paralysis either local or general, tetanic or other spasms; a rheumatic or neuralgic affection of the muscles of the face, jaw, tongue, lips, &c., or of the vocal cords; a condition of intoxication; chorea; or in some cases a habitual imitation of stammering. Stuttering, on the contrary, is seldom or never organic. The stutterer is often in perfect health, and the vocal organs are not in any way diseased or deformed. His difficulty consists in the momentary inability to pronounce certain words or syllables. The stoppage of sound usually takes place at the first syllable, though occasionally at the second or third. Words beginning with *k*, *t*, *g*, *d*, *p*, *b*, or *m*, usually give the stutterer the most trouble, because they require the closing of the lips or the pressing of the tongue against the roof of the mouth for their enunciation, and an immediate re-opening for the vowel which follows; while he keeps the lips closed, and compresses the cavity of the mouth in the attempt to force out the sound. Most stutters can sing without difficulty, the action of the vocal organs being much less frequently interrupted in singing than in speaking. Stutters may be classed

under two heads, mental or psychical and physical. The first class are influenced favorably or unfavorably by whatever affects their mental state. Under the stimulus of pleasant or joyful emotions, they experience little difficulty in conversation; under depressing influences, their utterance is seriously disturbed. The physical stutterer is rendered worse by unpleasant weather, great fatigue, vicious indulgence, and the excessive use of tobacco or alcoholic drinks. Among the causes of stuttering may be named abnormal excitability of the nervous system, diffidence, fear, and other kindred mental emotions; affections of the brain and spinal cord; and the involuntary imitation of chorea and ecstasy. Whatever tends to lessen the control of the individual over his muscles and nervous system will of course increase stuttering; and whatever develops the power of the will over the body will lessen it. The number of bad stammerers is estimated by Colombat at 1 in 5,000; but the number who suffer in a greater or less degree from defective utterance is certainly not less than 1 in 500. Only about $\frac{1}{10}$ of these are females.—The proper treatment of either stuttering or stammering is indicated by the cause which induces it. In the case of the stammerer there should be a thorough investigation for an organic cause, which if possible should be removed. Hence, the clipping of the uvula, the removal of a portion of the tonsils, or the excision of a wedge-shaped piece from a tongue too large for the mouth, the use of electrical or other remedies for the cure of paralysis, the cauterization of ulcers in the mouth, the removal of irregular or the insertion of false teeth, and the administration of tonics for debility, have each resulted in the cure of cases of stammering; but no one of these will answer for all or perhaps a majority of cases. In stuttering also, the cause, when ascertained, will indicate to some extent the method of cure. Temperance and abstinence from indulgences which affect the nervous system are of course necessary. The muscles must be educated to uniform obedience to the will, and the will trained to steady and intelligent control over the muscles and nerves. A course of lessons in enunciation, by a capable teacher, will often effect a complete cure. In the case of the stupid or volatile, this training must be long continued, if it is to effect any permanent improvement. The various remedies which have been proposed, most of which have had a temporary but none a general and permanent success, would form an interesting chapter in the history of charlatanism. Dr. J. M. Warren of Boston lays down the rules that treatment for impediments of speech should be commenced between the ages of 8 and 12; and that "little permanent advantage will be gained, in the majority of cases, unless the treatment be resolutely persevered in for one or two years."

STAMP ACTS, laws for the raising of revenue by requiring the use of paper or parchment

bearing a government stamp for various legal and other purposes. Such laws were introduced into England, in the reign of William and Mary, from Holland, and from that time to the present have multiplied, until now all or nearly all legal or commercial instruments are embraced within their requirements, as well as many things which cannot be thus described; as newspapers, legacies (by means of stamped receipts), and admission to practice as a physician, advocate, barrister, or attorney. So notaries public, bankers, pawnbrokers, and others must pay for a yearly license, which is given them on stamped paper or parchment. The provisions of these acts have varied very much from time to time. When the government stood in especial need of money, they were extended more widely, and the revenue from them increased. At present these acts are milder than formerly; but it is scarcely possible at this day to pursue any business, or enter into transactions, in England, without paying a tax to the government through a stamp. It is impossible to give here even a selection of the principal matters requiring stamps, and still less to enumerate them, the list in the recent consolidated acts covering more than 100 pages. The lowest amount noticed is one penny for a receipt of money over £2, and the highest is £22,500 on letters of administration on £1,000,000 property. The rate per centum varies considerably, being as a rule highest on the larger sums, but seems to be, in general, from less than one quarter of one per cent. to one per cent. The stamps are impressions made upon paper by the proper officers of government. If the instrument be written on parchment, the impression is attached to it. In a great number of cases, the instruments in blank and already stamped are bought at the stamp offices. In others, the instrument when properly prepared is brought to the office and stamped. The impression always states the price of the stamp, and sometimes the character or purpose of the document. It is obvious that such impressions may be easily forged, and it is said that they have been to a considerable extent. To prevent it, this forgery was made a capital offence by the act of William and Mary, and remained so until about 80 years ago, when the punishment of death was changed to that of transportation. An escape from the requirements of the acts is easily and certainly prevented by the provision that no document which needs a stamp and is without one can be offered in evidence or has any legal force whatever. And while the courts, regarding the stamp acts as penal instruments, apply to them the common rule of a strict interpretation against the act, they seem nevertheless to oppose and prevent the admission or use of any instrument so constructed as to evade payment of the duty; and the acts generally impose a penalty upon any evasion of their provisions.—As it is the purpose of the acts to raise a revenue in this way, they have multiplied, perhaps unnecessa-

rially, the number of the documents required to give validity to a transaction; and questions of this kind are frequently before the courts. Thus, if the terms of a stamped agreement are varied, there must be a new stamp; and an affidavit used in one stage of a suit, if offered for use in a later stage, must be restamped. When the instrument may lawfully be stamped after it is executed, sufficient time is allowed; 21 days, for example, in an agreement not under seal. If a stamped instrument is lost, or withheld by an opposing party, an unstamped copy may be used in evidence. So a witness may use an unstamped receipt or other instrument to refresh his memory. If stamps are spoiled so that they cannot be used, they may be returned to the office, and will be paid for, in the absence of all fraud. While the acts, and the courts in their construction and application of them, aim at effectually preventing all fraud upon the revenue, they endeavor, so far as this is consistent with the safety of the revenue, to prevent fraud or injustice from the accidental and unintentional violation of the stamp acts. For this purpose many instruments erroneously believed to be properly stamped, or accidentally prevented from being so, may be subsequently stamped and thus acquire legal validity. Our readers will not forget that the endeavor of England to impose stamp duties upon her transatlantic colonies in 1765, was among the efficient causes of the revolution which resulted in their independence.—Stamp acts, or analogous enactments, are widely used on the continent of Europe. In some countries, as in France, stamps appear to be used as well for the authentication of legal documents as for the purpose of revenue; and it is said that an important part of the income of the city of Paris is derived from this source.—This indirect method of raising a revenue has been much and earnestly discussed, and there are, of course, conflicting opinions as to its propriety or utility. It seems however to be too firmly established to be shaken. They who favor it generally rest their approval on the following grounds. It is easily collected, at small cost. It cannot be evaded without great difficulty, and not to any great extent. By a careful discrimination it may be made to lay upon all business transactions an equal or proportional burden. This burden is borne by none but those who profit by the transactions upon which it rests; and while a poll tax must necessarily bear no proportion to the payer's means, and a property or income tax is always open to evasion or fraud to a great extent, and an excise on manufactured articles is very often cumbersome, expensive, and inconvenient, the impost levied by means of the stamp acts serves to produce a large revenue with a great impartiality, and a less cost and embarrassment than perhaps any other form of taxation now practised by civilized nations. The produce of stamp duties in Great Britain for 1860 was £8,265,257 14s. 4d.

STANDARD, the most considerable banner of an army, or the national banner when displayed in the field, on public occasions, or at sea to distinguish the ships of one nation from those of another. In common parlance the term is synonymous with banner, flag, ensign, or colors. For some time previous to the revolutionary war, and even after the declaration of independence, a variety of flags were displayed in the revolted colonies of British America, emblematic of the popular grievances and of the particular arm of service. Frequent mention is made of union flags in the newspapers of 1774, but, from the absence of any description of the devices employed, it has been supposed that they were the common ensigns of the commercial marine, in which were blended the crosses of St. George and St. Andrew in commemoration of the union of England and Scotland. In March, 1775, a union flag with a red field was hoisted upon the liberty pole in New York, with the inscription: "George Rex, and the Liberties of America." The Connecticut troops bore upon their standards and drums the arms of the colony, with the motto: *Qui transtulit sustinet*; and by act of the provincial congress the standard of each regiment was distinguished by its color, as "for the seventh, blue; for the eighth, orange," &c. The flag displayed by Gen. Putnam on Prospect hill near Boston, July 18, 1775, was red in token of defiance, and bore on one side the motto of Connecticut, and on the other the words: "An Appeal to Heaven," which were adopted by a resolution of the provincial congress of Massachusetts, April 29, 1776, as the motto to be borne on the flag of the cruisers of that colony—"a white flag with a green pine tree." The first American flag unfurled in South Carolina, "a blue ground with a white crescent in the dexter corner," was designed by Col. Moultrie at the request of the council of safety, and was carried at the taking of Fort Johnston, Sept. 13, 1775. By a letter of Col. Joseph Reed, Oct. 20, 1775, it appears that the flag of the floating batteries was similar to that of the Massachusetts cruisers. The standard of the first American fleet was hoisted at Philadelphia, Dec. 22, 1775, by Paul Jones with his own hands, as Commodore Ezekiel Hopkins embarked on board his flag ship, the *Alfred*; it represented a rattlesnake on a yellow field, with the motto, "Don't tread on me"—a device suggested probably by the head pieces of many of the newspapers in the revolutionary interest, in which a disjointed snake divided into 13 parts, with the motto, "Join or die," was employed to typify the necessity of union. When this result had been accomplished, the device was changed into a united snake or into a rattlesnake about to strike. A paper attributed to Dr. Franklin gives an elaborate explanation of the reasons for selecting this device, founded upon the character and habits of the rattlesnake. The fleet did not sail from the Delaware capes until Feb. 17, 1776, when it car-

ried the flag known as the "Great Union," which was first displayed by Washington upon the heights before Boston, upon assuming the command of the newly organized army of the colonies, Jan. 1, 1776, and which consisted of the crosses of St. George and St. Andrew on a blue ground in the upper corner, with a field composed of alternate horizontal stripes of red and white, to indicate the union of the colonies for the maintenance of their rights within the empire of Great Britain. The combination of these two colors was probably suggested by the red flag of the army and the white one of the navy, previously in use, and the form of stripes by the order of Washington that officers of different grades should wear stripes of different colors "to prevent mistakes," and to enable "both officers and men to make themselves acquainted with the persons of all officers in general command." The emblems of British union having become inappropriate after the declaration of independence, it was ordered by congress, June 14, 1777, "that the flag of the 13 United States be 13 stripes, alternate red and white; that the union be 13 stars, white in a blue field, representing a new constellation." It is not known precisely to whom is due the credit of suggesting the stars for the union. The idea is supposed to have emanated from John Adams, who was then chairman of the board of war; and it has also been urged with considerable plausibility that the stars and stripes of the national standard were borrowed from the coat of arms of the Washington family, the shield of which presents a white or silver field traversed by two red bars, with three spur rowels or stars in the upper portion. The resolution of June 14 was not made public until Sept. 3, 1777, and the stars and stripes first figured conspicuously at the surrender of Burgoyne in the succeeding month; in December of the same year they were carried to Europe by Paul Jones on his ship, the *Ranger*. The flag, having been instituted on the representative principle, to designate the states of the united republic, remained unaltered until 1794, when, on motion of Mr. Bradley, senator from Vermont, which state, with Kentucky, had recently been admitted into the Union, it was resolved that from and after May 1, 1794, "the flag of the United States be 15 stripes," and that "the union be 15 stars," &c. The act of 1794 contained no provisions for future alterations, and until 1816 none were made, notwithstanding that in the mean time the states of Tennessee, Ohio, Louisiana, Indiana, and Mississippi were added to the Union. On the admission of Indiana in 1816 a committee was appointed, on motion of Mr. Wendover of New York, "to inquire into the expediency of altering the flag," by whom the whole subject was carefully examined. The proposition to carry out the principles of Bradley's act of 1794, which contemplated the addition of a star and a stripe for each state admitted into the Union, was deemed objectionable on the ground that

nothing would be left to recall the past; and by a similar course of reasoning a return to the 13 stars and 13 stripes prescribed by the act of 1777 was considered equally impracticable, as the past would then only be recognized and the present ignored. The flag of 1794 was, if possible, more objectionable than either of these. The credit of establishing the device finally agreed upon, and which is intended to illustrate at once the origin of the republic and its progress in material prosperity, is due to Capt. Samuel C. Reid of New York, who gained distinction by his defence of the private armed brig General Armstrong against a greatly superior British force at Fayal in Sept. 1814; and his suggestions were embodied in the report of the committee submitted Jan. 2, 1817. This proposed to retain the 13 stripes, alternate red and white, in commemoration of the 13 colonies which took the field in the struggle for independence, and to make the number of the stars (white on a blue field), representing the Union, correspond with that of the states, with the provision that a new star should be added on the 4th of July next succeeding the admission of any new state. A bill embodying these provisions was also reported, but the subject having been laid over until the next congress owing to press of business, a new committee reported through Mr. Wendover a bill identical with the former, which on April 4, 1818, became a law. The flag thus established was first hoisted over the hall of representatives at Washington on the 18th of the same month at 2 P. M., although, in accordance with the act, its legal existence could not be recognized until the 4th of July ensuing; and down to the present time it has continued to be the national standard of the American Union. Resolutions were introduced in the 85th congress offering the thanks of the nation to Captain Reid "for having designed and formed the present flag of the United States," but were overlooked amid the exciting questions which subsequently occupied the attention of the national legislature.

STANDISH, MILES, the first military leader of the Plymouth settlers in New England, born in Lancashire, England, about 1584, died in Duxbury, Mass., Oct. 3, 1656. He came to Plymouth with the first company in 1620, previous to which he had served in the army in the Netherlands. He was a man of great courage, energy, and determination, with a fiery temper, and rendered important services to the early settlers. He commanded frequent expeditions against the savages that annoyed the settlements, and by the boldness and skill of his attacks inspired them with great awe of his military prowess. He visited England in 1625 as an agent for the colony, and after his return settled at Duxbury, and for the remainder of his life held the office of magistrate or assistant for that town.

STANFIELD, CLARKSON, an English painter, born in Sunderland about 1798. In early life

he followed the sea, acquiring thereby a knowledge of marine scenery. He was afterward distinguished as a theatrical scene painter, became an exhibitor in the galleries of the British institution and the society of British artists, and in 1832 he was elected an associate of the royal academy, and in 1835 an academician. His works comprise almost every kind of landscape, but as a painter of sea pieces he enjoys a unique reputation. Among his pictures of this class are views in and about the chief cities of the Italian coast, and the coasts of Normandy, Holland, and England. As an imaginative painter in the same department he has produced many striking works, including his "Wreck of a Dutch East Indiaman on the Coast of Holland;" "The Victory, bearing the Body of Nelson, towed into Gibraltar;" "The Abandoned," the sentiment of which Ruskin characterized as "very grand;" and "The Battle of Trafalgar." He has occasionally attempted with success a very different class of subjects, familiar examples of which are "The French Troops fording the Magra," "The Battle of Roveredo," "The Pyrénées," and "St. Sebastian during the Siege under the Duke of Wellington." He has been a prolific designer for illustrated works, and has published a series of lithographic copies of his sketches, "The Moselle, the Rhine, and the Meuse" (fol., 1838). He is perhaps the most popular of living English landscape painters.

STANFORD, JOHN, D.D., an American clergyman and philanthropist, born at Wandsworth, England, Oct. 20, 1754, died in New York, Jan. 14, 1834. He studied medicine for a time, but engaged in teaching at Hammer-smith, near London. He had been brought up in the church of England, but united with the Baptist church, and in 1786 emigrated to the United States, spent a few months at Norfolk, Va., and then opened an academy at New York. In 1787 he became pastor of the first Baptist church, Providence, R. I., and while there wrote a history of that church. In Nov. 1789, he returned to New York, and again became a teacher; and in 1791 he commenced a course of Sunday evening lectures. A Baptist church having been formed through his exertions in 1794, he served in connection with his other duties as its pastor for the next 6 or 7 years. He continued teaching till 1818, when he finally relinquished his school. In 1808 he preached for the first time in the almshouse, and in 1811 became the chaplain of that institution. His field of labors ultimately embraced the prisons, hospitals, and charitable asylums of the city. He also gave instruction to classes of theological students. Beside the "History of the First Baptist Church of Providence," already mentioned, Dr. Stanford was the author of numerous tracts and small religious works, and published a number of addresses and discourses, and a collection of essays entitled "The Aged Christian's Companion" (8vo., 1829), which has passed through several editions.

STANHOPE. I. JAMES, earl, a British statesman and soldier, born in 1673, died in London, Feb. 5, 1721. He was the son of Alexander Stanhope, a brother of the 2d earl of Chesterfield and a diplomatist of some distinction under William III. Entering the military service at an early age, he was in 1694 commissioned a captain in the foot guards. After serving with credit in the wars in Flanders which terminated with the peace of Ryswiek, he participated in the disastrous expeditions of 1702 and 1704 to the Spanish peninsula; and in 1705, being then a brigadier-general, he shared in the exploits of the earl of Peterborough's brilliant Spanish campaign. In 1707 he was made major-general, in 1708 commander-in-chief of the British forces in Spain, and in the latter year effected the reduction of Minorca and the capture of Port Mahon. After gaining further important successes in Spain, he was on Nov. 27, 1710, surprised by the duke of Vendôme at Brihuega, and forced with his army of 2,000 men to capitulate. Subsequent to his return to England he held no military command, but became a prominent whig member of parliament, to which he had been regularly returned since 1702. Having distinguished himself by his opposition to the commercial treaty with France and on other occasions, he was appointed by George I. on his accession one of his principal secretaries of state, Viscount Townshend being the other. The intrigues of the earl of Sunderland, by whom Stanhope, it has been asserted, was incited to betray his ministerial colleagues, led to the retirement of Townshend, Walpole, and others of the cabinet; and Stanhope was in April, 1717, made first lord of the treasury, and a few months afterward raised to the peerage as Baron Stanhope of Elvaston and Viscount Stanhope of Mahon. In the succeeding year he resumed his office of secretary, Sunderland becoming first lord of the treasury, and was created Earl Stanhope. On Feb. 4, 1721, while replying with much heat to an attack upon the ministry by the duke of Wharton, he burst a blood vessel, which caused his death on the succeeding day. **II. CHARLES**, 8d earl, grandson of the preceding, born in Aug. 1753, died in 1816. By his first wife, a daughter of the earl of Chatham, he had 8 daughters, the eldest of whom was the eccentric Lady Hester Stanhope. Succeeding to his family honors in 1786, he became noted for his radical democratic opinions on the prominent questions of the day, in discussing which he carried the principles of the whigs, with whom he voted, to a point deemed so perilous by that party that none dared follow him; and in the latter years of his life he used to be called "the minority of one." As a mechanical inventor he is well known by the printing press which bears his name, by his improvements in the construction of locks for canals, and by two ingenious calculating machines, one of which performed addition and subtraction, and the other multiplication and division. He also gave considerable atten-

tion to the subject of electricity, and in 1779 published his theory of what is called the return stroke. His political works consist of a refutation of Price's "Plan for a Sinking Fund," a reply to Burke's "Reflections on the French Revolution," and an "Essay on Juries." **III. PHILIP HENRY**, 5th earl, a British statesman and author, grandson of the preceding, born at Walmer, Kent, in 1805. He was graduated at Oxford in 1827, and in 1830, being then known by his courtesy title of Lord Mahon, entered parliament as member for Wotton Bassett, upon the disfranchisement of which borough he was returned for Hertford. Being unseated on petition, he was reelected in 1835, and continued to represent Hertford until 1852. He has been conservative in politics, and held office during brief periods in the cabinets of the duke of Wellington and Sir Robert Peel. As a legislator he is favorably known by the copyright act of 1842, which he introduced and carried, and he occupies an important place among modern English writers of history and biography. His first work was the "Life of Belisarius" (8vo., 1829), succeeded by a "History of the War of Succession in Spain" (8vo., 1832), and the "History of England from the Peace of Utrecht to the Peace of Versailles, 1713-'88" (7 vols., 1836-'54). His remaining works comprise "Spain under Charles II." (8vo., 1840); "Life of Louis, Prince of Condé" (18mo., 1845); "Historical Essays contributed to the Quarterly Review" (8vo., 1849); a "Life of Joan of Arc" (1853); and a "Life of William Pitt" (4 vols. 8vo., 1861 *et seq.*). He has edited "The Letters of Philip Dormer Stanhope, Earl of Chesterfield" (1845; 2d edition, 5 vols. 8vo., 1853), and, in conjunction with Mr. Cardwell, 2 vols. of the "Memoirs by the Right Hon. Sir Robert Peel, Bart." (1856-'7), to be followed by a selection from his correspondence. During the publication of his history of England he entered into a controversy with Mr. Jared Sparks on the accuracy and value of the latter's edition of the "Writings of George Washington." He subsequently exonerated Mr. Sparks from the charges of serious "omissions and additions" originally preferred against him, but continued to "differ widely from him on the privileges and duties pertaining to an editor." Lord Stanhope succeeded to his title in 1855, since which time he has taken a less active part in public life. In 1884 he received the degree of D.O.L. from the university of Oxford, and since 1846 he has been president of the society of antiquaries. He was appointed by the duke of Wellington his literary executor.

STANHOPE, LADY HESTER LUOY, an eccentric English woman, born in London, March 12, 1776, died at Joon, in the Lebanon, June 28, 1839. She was the eldest child of Charles, 8d Earl Stanhope, by Hester, daughter of the great earl of Chatham, and in girlhood was remarkable for precocity, and boldness and independence of character. Unlike her father, who was almost a democrat in principle, she

prided herself upon her aristocratic birth, and the superior mental and physical qualities which she supposed to be its concomitants; and it was probably in consequence of this antagonism between parent and child that at an early age she entered the family of her uncle William Pitt, with whom she lived until his death, acting as his private secretary and sharing in all his confidences. Pitt having recommended his niece to the care of the nation, she received a pension of £1,200, which proving inadequate to support her according to her former rank and style, she retired to solitude in Wales. In 1810, disgusted with the artificial character of European society, and influenced also by the impression that a great destiny awaited her in the East, she resolved to expatriate herself. After spending several years in travel, during which she visited Jerusalem, Baalbec, Damascus, and Palmyra, at which last place she is said to have been crowned by 50,000 Arabs queen of the East, she established herself in 1813 at the deserted convent of Mar Elias, beside the little village of Joon, and within 8 miles of Sidon. Her striking manners and conversation, her munificence and reputation for extraordinary wealth, produced a strong impression upon the neighboring tribes and their chiefs, who learned to admire and ultimately to fear her. The old convent, perched upon an isolated eminence among the wildest scenery of the Lebanon, was soon converted into a fortress garrisoned by a band of Albanians, and became a refuge to all the persecuted and distressed who sought her assistance. Possessing a passion for intrigue and considerable diplomatic talent, she exercised a despotism over the surrounding country, fomenting and allaying commotions at her pleasure. So powerful was the influence which she wielded, that Ibrahim Pasha, when about to invade Syria in 1832, was constrained to solicit her neutrality. After the siege of Acre in the same year, she is said to have sheltered several hundred refugees. Whether for the purpose of awing her followers or from inward conviction, she practised astrology and other secret arts, and promulgated some peculiar religious sentiments which she held to the last. That her mind was diseased on certain points is clear from the fact that she kept in a magnificent stable two mares, on which she fancied she was to ride into Jerusalem with the Messiah at his next coming, to inaugurate the millennium. She treated with extreme rudeness many of the travellers who visited her, particularly Englishmen, and had an especial enmity against consuls and commercial agents, who, she said, "were intended to regulate merchants, and not to interfere with or control nobility." The extravagant state which she maintained and her numerous benefactions gradually brought pecuniary embarrassments, and during the latter years of her life she was constantly harassed by debts. Nothing, however, could tempt her to return to England, and she was forced to resort to

various dishonorable shifts to elude her creditors, dying at last with no European near her, and surrounded by a crowd of native servants, who plundered the house almost before life had left her body. She was buried in the garden adjoining her residence by the British consul at Beyrout and Dr. W. M. Thomson, an American missionary, the latter of whom, for several years her neighbor, thus sums up her qualities: "On most subjects she was not merely sane, but sensible, well informed, and extremely shrewd. She possessed extraordinary powers of conversation, and was perfectly fascinating to all with whom she chose to make herself agreeable. She was however whimsical, imperious, tyrannical, and at times revengeful in a high degree. Bold as a lion, she wore the dress of an emeer, weapons, pipe, and all; nor did she fail to rule her Albanian guards and her servants with absolute authority. She kept spies in the principal cities, and at the residences of pashas and emeers, and knew every thing that was going forward in the country." Her "Memoirs as related by Herself" (3 vols. 8vo.), and "Travels" (3 vols. 8vo.) by Dr. Meryon, who had been for several years her physician, were published soon after her death.

STANHOPE, PHILIP DORMER. See CHESTERFIELD.

STANISLAS I. LESZCZYNSKI, king of Poland, and afterward duke of Lorraine and Bar, born in Lemberg, Galicia, April 20, 1677, died in Lunéville, Feb. 28, 1766. He was the son of Raphael Leszczynski, palatine of Posen and treasurer of Poland, and was appointed archbutler of the crown by Augustus II. When war broke out between Charles XII. of Sweden and that prince, he was in 1704 sent on a mission to the former by the diet at Warsaw, won the good graces of the conqueror, and through his influence was in the same year elected to the throne of Poland. This he held but a few years; his patron having been defeated at Pultowa in 1709, he was unable to resist his competitor Augustus II., left Poland in 1712, and took refuge in Pomerania, and then in Sweden. For the sake of peace he was willing to abdicate, and having gone for this purpose to Charles XII., then at Bender, was taken prisoner by the hospodar of Moldavia and delivered to the Turks; being released in 1714, he returned to Sweden, was appointed governor of Deux-Ponts by Charles XII., and remained there until that prince's death in 1719. Without protection and bereft of his patrimonial estates, he sought an asylum in France, and the regent Philip of Orleans granted him a pension and permission to reside at Wissembourg, Alsace, where he lived obscurely with his only daughter Marie Leszczynska. He had given up all ambitious aspirations, when he was suddenly apprised that the hand of his daughter was desired for Louis XV., to whom she was married Sept. 5, 1725. In 1733, on the death of Augustus II., he was recalled to

Poland by his adherents, who hoped that he would be supported by the French government; he however received only lukewarm assistance, while Russia strongly favored his competitor Augustus III.; he was obliged to retire to Dantzig, where he was besieged by a Russian army, and after a bold resistance of several months had a remarkable escape. In accordance with the preliminaries of the peace of Vienna in 1738, he resigned his pretensions to the throne of Poland, but was allowed to preserve his royal title; his confiscated estates were restored to him, and he received beside from Austria the duchies of Lorraine and Bar, which on his death were to be united to France. He died after 3 weeks' suffering, caused by his garments taking fire as he was reading. He has been deservedly styled *Le Bienfaisant*. He left several essays on philosophy, politics, and morals, which have been printed under the title of *Œuvres du philosophe bienfaisant* (4 vols. 8vo. and 4 vols. 12mo., 1765), a selection from which (*Œuvres choisies de Stanislas, roi de Pologne, duc de Lorraine et de Bar*) was published in 1825.

STANISLAS AUGUSTUS, king of Poland. See POLAND, vol. xiii. pp. 432-'8.

STANISLAUS, a central co. of California, bounded N. in part by the Stanislaus, and drained by the San Joaquin and Tuolumne rivers; area, nearly 900 sq. m.; pop. in 1860, 1245. The surface is generally hilly, and the soil well adapted for farming and grazing. The chief productions in 1858 were 18,500 bushels of wheat, 48,000 of barley, and 75,000 lbs. of wool. Gold and other minerals are found. Capital, La Grange.

STANLEY, a S. W. co. of North Carolina, bounded E. by the Yadkin and S. by Rocky river; area, 280 sq. m.; pop. in 1860, 7,801, of whom 1,169 were slaves. The surface is mountainous and the soil generally fertile. The productions in 1860 were 81,267 bushels of wheat, 203,281 of Indian corn, and 22,877 of oats. There were 2 tanneries, 6 grist mills, 21 churches, and 600 pupils attending public schools. Gold and silver in considerable quantities have been found. Capital, Albemarle.

STANLEY, EDWARD, an English divine and author, born in London, Jan. 1, 1779, died at Brahan castle, Ross-shire, Sept. 6, 1849. He was educated at St. John's college, Cambridge, and in 1805 presented to the living of Alderley, which he retained for the next 32 years. He gave much attention to the natural history of his neighborhood, and became a contributor on such topics to "Blackwood's Magazine" and other periodicals. His "Familiar History of Birds, their Nature, Habits, and Instincts" (2 vols., 1835), was published under the auspices of the society for promoting Christian knowledge. In 1837 he was offered by Lord Melbourne the bishopric of Norwich, which he accepted with some reluctance. His views were of so liberal a character, that he was accused of latitudinarianism. His "Addresses and Charges" were

published in 1851, with a memoir by his son Arthur Penrhyn Stanley. His remaining works comprise "Questions on the Bible," and a number of occasional sermons, pamphlets, &c. He was a fellow of the royal society, and president of the Linnean society.—ARTHUR PENRHYN, an English clergyman and author, son of the preceding, born in Alderley, Dec. 13, 1815. He was educated at Rugby under Dr. Arnold, and in 1838 was graduated at University college, Oxford, where he subsequently resided for several years as tutor. In 1851 he was appointed one of the canons of Canterbury, which office he still holds, and he was also one of the chaplains of Prince Albert. In 1856 he was elected regius professor of ecclesiastical history at Oxford. In 1849 he preached the funeral sermon of Dr. Arnold in the chapel of Rugby school, whose "Life and Correspondence" he published in 1844. He has also published "Sermons and Essays on the Apostolic Age" (Oxford, 1847); a "Lecture on the Study of Modern History" (1854); "Historical Memorials of Canterbury" (1855); "Sinai and Palestine in Connection with their History" (2d ed., 1857); "History of the Eastern Church" (1861); and several occasional sermons and lectures. He is a leader of the so called "Broad Church" party in England.

STANLEY, EDWARD HENRY SMITH, styled by courtesy Lord Stanley, an English statesman, born at Knowsley Park, July 21, 1826. He is the eldest son of the present earl of Derby, and was educated at Rugby under Dr. Arnold, and at Trinity college, Cambridge. Having contested unsuccessfully the representation of Lancaster in parliament, he made an extended tour in North America, visiting Canada, the United States, and the West India islands, and during his absence was, in Dec. 1848, elected for the borough of Lynn-Regis. During a subsequent visit to India he was appointed under secretary of state for foreign affairs in the first administration of his father (Feb. 27 to Dec. 28, 1852); and at the general election of 1852 he was again returned for Lynn-Regis, which he has continued to represent down to the present time. In the spring of 1853 he submitted to the house of commons a motion which contemplated a more complete reform of Indian affairs than the measures proposed by the Aberdeen-Russell administration, and which was a foreshadowing of the policy adopted in 1858. Although a conservative in politics, Lord Stanley showed such liberal views on many questions, particularly the abolition of church rates, and recommended himself to public approval so strongly by his efforts for the intellectual improvement of the lower classes through the establishment of mechanics' institutes and libraries and the promotion of popular education, that on the death of Sir William Molesworth in 1855 he was offered by Lord Palmerston the seals of the colonial office, which he declined. He however accepted the office in the second Derby cabinet,

formed in Feb. 1858, and in the succeeding May assumed the presidency of the board of control upon the resignation of the earl of Ellenborough, with the title of "her majesty's commissioner for the affairs of India." Upon the transfer of the government of India from the East India company to the imperial crown (Aug. 1858), he became the first secretary of the new department of India then created. Since the retirement of the Derby ministry in June, 1859, he has not held office.

STANLEY, THOMAS, an English author, born in 1625, died in London, April 12, 1678. He was educated at Pembroke hall, Oxford, and subsequently resided for several years in the Middle Temple. In 1649 he published a volume of "Poems and Translations," followed in 1655-'60 by his "History of Philosophy, containing the Lives, Opinions, Actions, and Discourses of the Philosophers of every Sect" (8 vols. fol.), by far his most important production. A Latin translation of it by Olearius was published at Leipsic in 1711. In 1668 appeared his edition of *Æschylus*, including the fragments and the Greek scholia, together with a commentary and a Latin version. A reprint of this edition, with the commentary enlarged and corrected, was published at Cambridge in 1809 by Dr. Butler (4 vols. 4to.). In 1814-'15 appeared an edition of his poems with a biographical memoir by Sir Egerton Brydges.

STANZA (Ital.), a certain number of lines regularly adjusted to each other, and forming one of the divisions of a poem. The stanza should properly terminate with a full point or pause, whence its name, which signifies a station or resting place; but in practice this rule is not always observed, even in such varieties as the Spenserian stanza, where the metre would seem especially to require a full pause.

STAR. See ASTRONOMY.

STAR CHAMBER, COURT OF THE (*curia camera stellata*, so called from the gilded stars on the ceiling of the old council chamber of the palace of Westminster, in which it sat), a tribunal famous in the political history of England, and of which mention is made as early as the reign of Edward III. It appears to have been then, and for upward of a century and a half afterward, identical with the ancient *concilium regis*, or king's ordinary council, which alone exercised jurisdiction, the *concilium secretum*, or privy council, being a deliberative body; and at the accession of Henry VII. its powers had become so greatly abridged by restraining statutes as to render it almost inoperative as a court of justice. The statute of 8 Henry VII. (1488) placed the jurisdiction of the council, or rather of a part of the council, on a permanent basis by establishing a court composed of three high officers of state (to whom a fourth was subsequently added), a bishop and temporal lord of the council, and two justices of the courts of Westminster, which took cognizance of riots, perjury, the misbehavior of sheriffs, and other offences against the administration of justice,

in examining which they invariably proceeded without the assistance of a jury. This tribunal, however, was distinct from the council itself, of which it may be considered a committee having delegated powers; nor did the act cited give the first legal authority to the criminal jurisdiction exercised by that body. It received an augmentation of its powers by act of 31 Henry VIII., "which," says Sir Thomas Smith, "was at that time marvellous necessary to do to repress the insolence of the noblemen and gentlemen of the north parts of England, who made their force their law;" and after an existence of nearly 60 years it was during the minority of Edward VI. merged in the general body of the council, which thenceforth, as in earlier times, constituted the real court of the star chamber. The latter continued under the Tudors and their successors, in spite of numerous restraining statutes, to exercise a jurisdiction, particularly in criminal matters, unauthorized by the act of Henry VII. erecting a new court, and which gradually rendered it one of the most odious instruments in overthrowing the liberties of the people. Every misdemeanor, and especially those of public importance for which the law, owing to the timidity and narrow-mindedness of its judicial interpreters, had provided no sufficient punishment, seems to have come within the scope of its inquiry. Among these were corruption, breach of trust, and malfeasance in public affairs, attempts to commit felony, or breach of proclamations; and to such an extent was its authority stretched under the Stuarts, that, according to Clarendon, "any disrespect to any acts of state, or to the persons of statesmen, was in no time more penal, and the foundations of right never more in danger to be destroyed." The mode of process was generally by information filed at the suit of the attorney-general, or, in certain cases, of a private relator, and in other respects resembled that familiar to the court of chancery. Although the court was held incompetent to pronounce sentence of death, fines, imprisonment, the pillory, whipping, branding, and various species of maiming were freely resorted to; and "the greater certainty of conviction," says Hallam, "and the greater severity of the punishment, rendered it incomparably more formidable than the ordinary benches of justice." According to the same authority, "the object of drawing so large a number of criminal cases into the star chamber seems to have been twofold: first, to inure men's minds to an authority more immediately connected with the crown than the ordinary courts of law, and less tied down to any rules of pleading or evidence; secondly, to eke out a scanty revenue by penalties and forfeitures." After flourishing with constantly increasing power for upward of a century, the court of the star chamber was finally abolished by act of parliament in 1641, although such was the reverence for precedent still remaining, that at first nothing more than a bill to

regulate the tribunal was intended, and according to Clarendon the act finally passed was due to a suggestion from one not connected with the more ardent reformers.

STAR FISH, the popular name of the radiated animals of the class of echinoderms and the order *asteroidea*, well exemplified by the common species of the New England coasts, the 5-fingered Jack of the sailors. The quinary arrangement prevails to a remarkable extent in the star fishes; one of the problems proposed by Sir Thomas Browne was: "Why, among sea stars, nature chiefly delighteth in 5 points?" The body of the star fishes is depressed, and divided into rays like a star; the upper surface is studded with rough knobs, varying in color with the species, but generally reddish or yellowish, between which are the openings of many very minute tubes for the passage of water in and out of the body; the skin is coriaceous, and contains the above named corpuscles, beneath which is a cutaneous skeleton of porous calcareous pieces, movably articulated, and extending on the lower surface from the mouth in the centre to the end of the rays. In the lacunæ between these pieces are the ambulacral pores, along the centre of the lower surface of each ray, through which are protruded the ambulacral tubes; these are the principal organs of locomotion, are arranged in a double or quadruple row, and are provided with contractile sacs or vesicles on the inner surface of the envelope; the tubes are constantly in motion, each ending in a suction disk, and pull the animal along as by the successive action of so many little anchors. On the external edges of the rays are series of stiff spines, probably serving for protection, and at the end of each ray is a small reddish eye speck; there are also scattered over the upper surface small processes ending in calcareous hooks or pincers. The mouth opens into the stomachal cavity, from which branching cæcal tubes extend to the extremity of each arm; having no long tentacles like the sea anemone (*actinia*), the stomach can be everted over their food and then be turned back again; the mouth is very dilatable, and will admit large mollusks with the shell, the hard parts being ejected after the soft portions are digested. There is great variety in the spreading, division, and subdivision of the arms, and in the relative size of the central disk, but all are arranged after the radiated plan; the rays can be bent in any direction, according to the will or need of the animal, by the contractile skin and muscles. The slender ophiurans progress by the undulatory movements of the rays, which, when very slender, long, and branching, have no eyes at the tips; there is generally no anal aperture, and when present it is on the dorsal surface. By the action of cilia water flows through the body, through the aquiferous system, distending and protruding the ambulacral feet, filling the circular vessel around the mouth, and serving for respiration, which, according to Siebold,

is performed partly by the vesicular appendages attached to the central ring; all the viscera are bathed in water, and respiration is also effected through the delicate blood vessels thereon distributed. The vascular system is very simple; the nervous ganglia are 5, arranged around the mouth, each sending filaments to the arm at whose base it lies; the sense of touch is very acute; the power of reproducing lost parts is very great, as every one knows from the mutilated and irregular specimens so commonly seen in the sea and in aquaria. On the upper surface, to one side of the centre and between two of the arms, is a round bright-colored spot, the madreporic plate or body, communicating with a canal leading to the water vessel around the mouth; this, according to Sharpey, is a sieve through which the water is filtered as it enters the aquiferous system for circulation through the whole body. They propagate by eggs only, and the sexes are in separate individuals; the larvæ are at first oval, ciliated bodies, without external organs or distinct parts; from these, which have a strictly bilateral symmetry, the radiated perfect animal is developed, at various stages of its growth, by a process of internal gemmation. The crinoid *comatula*, or feather star, free when adult, has its young attached on a long slender stem; Sars, a Norwegian naturalist, has traced the growth of *echinaster* from a spheroidal free-moving mass to the perfect star fish. Some species secrete a reddish fluid on the surface, probably the coloring matter, often irritating to the skin of persons handling them; according to DeLongchamps, they can inject a fluid into the shells of their victims, which stupefies and renders them an easy prey. Rymer Jones says star fishes may be considered as mere walking stomachs, their office in the economy of nature being to devour all kinds of garbage which would otherwise accumulate on the shores; they eat also living crustaceans, mollusks, and even small fish, and are believed to be very destructive to oysters; they are not used as food by man, but are in many places highly esteemed as manure. For a popular account of the British species the reader is referred to the "History of British Starfishes," by Edward Forbes (London, 1841), illustrated by excellent figures. In that work are described *comatula* (Lam.), the crinoid feather star; *ophiura* (Lam.), the sand star; *ophiocoma* (Ag.), the brittle star, so named from the facility with which the delicate arms are broken, but which are also readily repaired; *astrophyton* (Link), the Medusa's head, so called from the curling and interlacing of the very numerous ends of the rays; *uraster* (Ag.), the cross fish; *solaster* (Forbes), the sun star; *palmipes* (Link), the bird's foot star; *goniaster* (Ag.), the cushion star; and *asterias aurantiaca* (Linn.), the common star fish. The common star fish of the North American coast (*asterias rubens*, Linn.), generally considered the same as the European species, is too well known to need description;

the colors vary from reddish to yellowish, and the diameter from an inch to more than a foot; it is a very common inhabitant of public and private aquaria, and very interesting to study.

STAR OF BETHLEHEM (*ornithogalum umbellatum*, Linn.), a pretty liliaceous plant with white bulbs, numerous radical smooth green leaves striped with a white longitudinal line, and corymbose racemes of starry white flowers consisting of 6 sepals, greenish without and with white margins. The plant is a native of Europe, but, escaping from gardens, has become naturalized in fields and orchards in the United States by means of its tendency to multiply its bulbs, which, remarkably tenacious of life, have been conveyed from the compost heap and barn yard. The foliage is however very transient, perishing in early summer, so that its presence is not very detrimental to grass. There are many species of the *ornithogalum* which bear the same trivial name.

STARBOARD, the right hand side of a vessel to a person standing in the stern and looking toward the bow; opposed to larboard.

STARCH (also called amylaceous matter, and fecula), a proximate vegetable principle existing in almost all plants. It has also been detected in animal tissues, in the brain, and in some other organs when these are in a diseased condition; but being recently found always present in dust wherever collected, it is not improbable that the slight quantities observed in these matters may have been derived from this source. Its composition is represented by the formula $C_{12}H_{10}O_{10}$, and differs from that of grape sugar only by the latter containing the elements of 4 atoms of water in addition. By artificially producing this combination with water, starch is wholly converted into this sugar. In the animal system its elements readily enter into new combinations, and by its deoxidation it is supposed that the fats and fixed oils are produced that are found in both the animal and vegetable kingdoms. Its specific action is regarded as promoting animal heat and respiration. That it must play an important part in the animal as well as in the vegetable economy, is evident from the fact that it is the chief ingredient in most vegetable substances employed for food. In the farinaceous grains, as rice, barley, and maize, it exists in great purity. In wheat it is associated with gluten; in beans, peas, and other leguminous seeds, and also in oats, with saccharine matter; in potatoes, rye, and Windsor beans, with viscous mucilage; in the emulsive seeds, that afford oil by expression, as the nuts, linseed, and cocoa, with fixed oil and mucilage. In some roots, as those of different species of *arum* and of the *manihot utilisima* (see CASSAVA), it is accompanied by a poisonous juice, which however does not interfere with its easy separation and conversion into simple articles of food, as arrowroot, cassava bread, &c. From wheat flour, the raspings of potatoes, and similar substances, starch is readily obtained by kneading

them with cold water on a cloth strainer. The fluid passes through milky from the particles of starch taken along with it, and being left to repose, these after a time subside. When pure they appear as a white glistening powder; and when magnified 800 to 400 times, distinct grains are seen of flattened ovate forms, varying in size and exhibiting peculiar marks according to the particular vegetables that furnished them. Such are the concentric rings or *rugæ* surrounding a minute circular hole or hilum at one or both ends of the granule. Thus it is that the adulteration of wheat flour by potato starch or flour may be detected. Several phenomena exhibited by starch have led chemists to the opinion that the microscopic granules are made up of a thin integument, which is insoluble in cold water and contains the same substance within, but in a soluble condition. When starch is ground in a mortar it is rendered partially soluble in cold water, and the same effect is produced by roasting it slightly. (See DEXTRINE.) But without this preparation starch may remain in water unchanged until the temperature is raised to a little more than 140° . The granules then absorb water and swell, and the mixture suddenly assumes a viscous pasty condition, in which state it is applied by laundresses to stiffening linen. A cold solution of soda or potash containing two per cent. or more of alkali will also cause the granules to swell and form a tenacious paste; but if much water be then added, a small portion of the starch only remains in solution, the rest subsiding. The presence of starch is recognized by the blue color it acquires on the addition of free iodine to its solution, the intensity of the color increasing with the proportion of iodine employed, till with a large excess of this it is blackish blue. At a temperature of 200° the solution becomes colorless, and on cooling recovers its former shade. Boiling for some time destroys the color altogether, the starch first forming dextrine and then sugar. The presence of sulphuric acid hastens this change. Starch is insoluble in alcohol and ether. In its commercial form it is agglutinated in columnar masses, which are easily reduced to powder. It is without smell or taste, and when pressed in the fingers emits a peculiar sound and feels as if elastic. Its specific gravity is about 1.5. Its properties as an aliment differ somewhat with the sources that furnish it; thus, wheat starch is considered the most nutritious, probably from the presence of some gluten; arrowroot starch is the most digestible and the most free from gluten; starch from potatoes and rice is regarded as the poorest aliment, neither nutritious nor digestible.—There are but few historical notices of starch. Pliny speaks of it as being made in the island of Ohio, and the best from summer wheat. Nothing more is known of its history until the time of Queen Elizabeth, when it was in use for stiffening the enormous ruffs of that period. It must have been rather an inferior

article, as in the occasional allusions to it that have been preserved it is spoken of as of yellow or greenish color. In the last century the manufacture attained considerable importance in England; and starch was applied to numerous uses in the arts, in medicine, and for purposes of the toilet. It was employed with snail and the stone blue or indigo color to stiffen and clear linens, as still practised by laundresses; in printing with colors it was used in strong gum water to make them work more freely and prevent their cracking; and the perfumers employed it in making their hair powders. In the reigns of Anne and George I., II., and III., the use of any other material as a substitute for starch in any of its applications was most strictly prohibited under severe penalties, and the manufacture was subject to extraordinary restrictions and taxes, most of which continued in force until 1833. About the close of the century its production was a subject of no little interest. In 1796 the society of arts awarded a prize medal to a Mrs. Gibbs of Portland for her discovery of the *arum maculatum* as a fruitful source of it, and the starch thus obtained was afterward sold as the Portland arrowroot. The same year Lord William Murray discovered a method of extracting it from horse chestnuts. The great development of the cotton manufacture created a new demand for starch, and the calico print works consumed it in enormous quantities. In 1859 a single establishment of this kind in Manchester used 6,000 cwt.—Starch is manufactured in different countries from those vegetable products that yield it most cheaply: in England from wheat, barley, and rice; on the continent from potatoes and leguminous seeds; and in France from the horse chestnut also, which has been collected of late years for the factory at Nanterre at prices equal to those for which potatoes are sometimes sold there. In the United States Indian corn and potatoes are most commonly used for starch. The application of the former to this use was patented by James Colman in 1841, and was successfully practised by Thomas Kingsford of Oswego, N. Y., in 1842. In 1849 he had a large factory at that place, which is still in successful operation under the direction of Messrs. T. Kingsford and son, having up to the end of the year 1860 made nearly 20,000 tons of starch. Its annual production for 5 years was as follows: 1856, 6,828,453 lbs.; 1857, 8,018,778 lbs.; 1858, 8,686,516 lbs.; 1859, 6,747,586 lbs.; 1860, 8,500,000 lbs.; far exceeding that of any other starch factory in the world for the same time. The total consumption of raw material in the 12 years from Jan. 1, 1849, was 2,476,000 bushels of Indian corn and 164,448 bushels of wheat, beside some damaged flour. The boxes for packing the starch have required 15,000,000 feet of basswood, supplied chiefly by the farmers in the neighborhood. The building has a front of 510 feet, and extends back over the Oswego river 250 feet. Its flooring covers 250,600

feet, or nearly 6 acres. For grinding the corn there are 16 pairs of buhrstones, and 6 pairs of large, heavy iron rollers. The river furnishes the power to drive the machinery, and a steam engine of 150 horse power is provided to make up any deficiency in very dry seasons. The vats employed in purifying the starch have a capacity of 2,200,000 gallons, and the length of gutters for conveying and distributing the starch waters is over 8 miles. A similar factory, almost or quite equal to this in capacity, commenced operations at Glen Cove, on Long island, in 1858. This also uses Indian corn, which is more cheaply transported from the western states than the starch from it would be. The product for each bushel is about 23 lbs., and the boxes of the starch, on account of their bulk and the extra care they require, make more expensive freight than the raw material. Potato starch factories are more numerous, but not so extensive. In the town of Stowe, Vt., there are 5 of them, each one of which consumes from 16,000 to 20,000 bushels of potatoes yearly, and produces about 8 lbs. of starch to the bushel.—The production in starch of the several materials employed in the manufacture is variously given by different authorities, probably by reason of the influence on the same plant of difference of soil and climate, and its condition as regards maturity, and possibly also of the more or less complete separation of the starch from other accompanying substances; and some perhaps give results of the factories, and others of the laboratories; and some of the grains, and others of their flour. Thus in wheat the proportion of starch is rated from 85 to 77 per cent., or as an average at 60; rice contains from 75 to 87 per cent.; Indian corn, 64.5 to 80; barley, 60 to 68; rye, 60 to 65.5; oats, 87 to 65; buckwheat, 44 to 52; peas and beans, 37 to 66; horse chestnut, 25; potatoes and arrowroot, 20. Wheat is treated by two processes. The old method is to expose the flour mixed with water and the spent waters of previous operations to fermentation for several weeks. The gluten undergoes putrefaction, emitting a most noisome odor. The sugar and a portion of the starch are converted into alcohol, and a part of this into lactic and acetic acids, which dissolve the gluten that has escaped putrefaction. Thorough washing and draining remove the soluble matters, and the starch left behind is next dried in blocks about 6 inches square; as the water escapes from them, the masses break up into the columnar fragments peculiar to starch. The other method, introduced by M. Émile Martin of Vervins, France, consists in kneading the flour into dough with water, and then washing on a sieve of No. 120 wire in a stream of water as long as the water passes through milky. The starch in suspension and the sugary portion in solution are caught below the sieve, and the gluten nearly all remains behind in a sticky mass. What passes through is left to ferment 24 hours in an oven

at 68° F., and a little leaven is added, or the skimmings of a former operation, to hasten the process. The portion of gluten carried through with the starch is thus separated and removed by skimming. The starch is then treated like that otherwise obtained. The product by this method is about 50 per cent. of the weight of the flour, while by the other process it is only from 85 to 40 per cent. Nearly the whole of the gluten also is saved in a condition suitable for food, either by mixing it with flour and making of it macaroni and similar pastes, or, as recommended by M. Robine, with boiled potatoes, and thus making a cheap and nutritious bread, by adding to the potatoes a nutritive element in which they are deficient. Potato starch is made from rasped or grated potatoes, by a process similar to that just described. This variety does not assume the columnar form in drying, and is also peculiar in retaining a large amount of moisture, generally 20 per cent., or when saturated 28 per cent. It is largely consumed for a variety of farinaceous preparations sold by the druggists as delicate food for invalids, under numerous high-sounding names. (See ADULTERATION.)—The corn used for starch is the white flint kind. Received at the factory, it is hoisted to the top of the building, winnowed to remove foreign substances, and then transferred to vats, where it is long soaked before grinding. It is run through troughs with water to the mills, and when ground the mixed meal and water is conveyed in a similar manner to the tubs in which the separation of the starch is effected. The gluten fluid that flows from these has a musty and disagreeable odor and appearance in the troughs, and the substance lacks when concentrated the consistency of wheat gluten, not "rising" like it in fermentation by the expansive action of the carbonic acid gas generated in this process. Its only value is for feeding horses, cattle, and swine. The starch fluid is conveyed through troughs to great vats in the basement of the building, where the water is partially removed, and then it flows into smaller wooden vessels from which a portion of the surplus water drains away through a cloth laid in the bottom of each. The mass of starch, then tolerably solid, is placed upon shelves made of loose bricks, when more moisture escapes by absorption and evaporation. Kiln drying finishes the process, and the starch is obtained in prismatic forms ready to be put up in papers or boxes for the market.—Rice is treated by a process patented in 1840 by Mr. Orlando Jones, which is also quite as applicable to the other grains, and by the use of which the offensive odors from the putrefactive fermentation are avoided. The rice is macerated in a weak alkaline solution, a gallon of water to every 2 lbs. of rice, and about 200 grains of caustic soda or potash to the gallon. Of this strength the solution takes up the gluten, leaving the starch. After standing about 24 hours, the alkaline li-

quid is drawn off, and the rice after being well washed is drained, and is then ground into flour. A fresh quantity of lye is added to it, and it is again digested for 24 hours, with frequent stirring. It is now left for 70 hours, in which time the dissolved gluten rises and is all found in a turbid, yellowish stratum at the top. This portion is carefully drawn off, leaving the fibrous portion of the grain at the bottom intermixed and covered with starch. The deposit is then stirred up and washed with abundance of cold water, and the mixture being left to repose, the fibrous portion is deposited with very little starch, and the remainder is drawn off by a siphon through a fine sieve into a cistern. Further washings of the deposit are added to this, and the water is finally removed, and the starch is dried in the usual way. The gluten is recovered by neutralizing its solution with the exact quantity of sulphuric acid required for this, when it is set free and falls in flakes to the bottom. These are collected, washed, and ground into flour, when the substance is prepared for culinary purposes. This process applied to wheat results in the saving of all the gluten for food.—The principal use of starch has already been noticed. It has at present a very limited application in medicine; it is used externally as an absorbent of irritating secretions; it may also be given as an antidote to iodine taken in poisonous quantities. Those varieties described under ARROWROOT, CASSAVA, and SAGO, form a mild nutritious diet for the sick. Starch is sometimes adulterated with carbonate and sulphate of lime, and is purposely charged with water, sometimes to the extent of 12 per cent.—The importations of starch into the United States in 1860 amounted only to \$1,400, the largest quantities coming from Scotland, China, and England.—The subject of starch is treated by Dumas in *Chimie appliquée*, vol. vi., and by Parnell in "Applied Chemistry," and the manufacture from the potato is described by M. Payen in *Précis de chimie industrielle* (Paris, 1851).

STARGAZER, a spiny-rayed percoid fish of the family *trachinida* or weevers, and genus *uranoscopus* (Linn.), so called from the position of the eyes, which look directly upward. The body is elongated, covered with smooth cycloid scales; head depressed, large and wide, bony and rough, with the gape ascending or vertically cleft, the upper jaw the shorter, and the teeth small and crowded on the jaws, palate, and vomer; branchiostegal rays 6; dorsals 2, of which the 1st is small and spinous, the 2d and the anal long; ventrals in front of the large pectorals and on the throat; anus very far forward; air bladder absent. In some of the family the dorsal and opercular spines are capable of inflicting painful wounds; they have the power of raising the eyeballs from and retracting them within their sockets. There are more than a dozen species of the genus, mostly East Indian, of which the best known is the *U. scaber* (Linn.) of the Mediterranean, about a foot

long, of a grayish brown color above, with irregular series of whitish spots and grayish white below; ugly as it is, some people eat it. This was well known to the ancients, and Aristotle correctly describes the gall bladder as larger than in most other fishes; it is also called *collionymus* by the old authors, and is proverbially referred to by dramatic writers as the emblem of an angry man; the bile was formerly supposed to possess great medicinal virtues in defective vision and hearing, and in arresting fungous growths. On the coast of South Carolina has been found the *U. anoplos* (Cuv.), about 2 inches long, greenish above with minute black dots, and silvery below; the cheeks are unarmed. These fishes live on the bottom in deep water, burying all but the head in the sand or mud, and there lying in wait for prey; they are voracious, and like other ground fish some have sensitive barbels about the mouth; though the gills are widely open, they live a long time out of water; some have a slender fleshy filament in front of the tongue, which can be protruded, probably to attract fishes within reach of their jaws, like the cutaneous appendages on the head of the goose fish (*Lophius*).

STARK. I. A. N. E. co. of Ohio, drained by the Tuscarawas river and its branches; area, 570 sq. m.; pop. in 1860, 42,976. The surface is undulating, and the soil a rich, sandy loam. Coal and limestone are abundant. Swine are largely exported, and it produces more wheat and butter than any other county in the state. The productions in 1850 were 590,594 bushels of wheat, 578,171 of Indian corn, 414,434 of oats, 41,746 tons of hay, 275,654 lbs. of wool, and 1,211,021 lbs. of butter. There were 5 newspaper offices, 98 churches, and 13,290 pupils attending public schools. It is intersected by the Pittsburg, Fort Wayne, and Chicago, and the Cleveland and Pittsburg railroads, and the Ohio canal. Capital, Canton.

II. A. N. W. co. of Ind., drained by the Yellow and Kankakee rivers; area, 432 sq. m.; pop. in 1850, 557; in 1860, 2,195. The surface is level and in many places marshy, with several small lakes, and the soil is fertile. The productions in 1850 were 3,153 bushels of wheat, 11,170 of Indian corn, and 698 tons of hay. Capital, Knox.

III. A. N. W. co. of Ill., intersected by the Spoon river; area, 290 sq. m.; pop. in 1860, 9,004. The surface is partly prairie and the soil fertile. The productions in 1850 were 54,327 bushels of wheat, 812,475 of Indian corn, 50,703 of oats, and 5,680 tons of hay. Capital, Toulon.

STARK, JOHN, an officer in the American revolution, born at Londonderry, N. H., Aug. 23, 1728, died at Manchester, N. H., May 8, 1822. In 1752 he went with 3 friends on a hunting expedition to Baker's river in the N. part of the state remote from the settlements, and while separated from his companions was captured by the St. Francis Indians, and remained with them several months until ransomed by the Massachusetts commissioners.

During his stay with the Indians he became very popular among them by his frequent exhibitions of courage and independence, and was adopted into the tribe. In 1754 he joined the rangers under Major Rogers in the war against the French and Indians, in 1756 was made a lieutenant, and in 1757 a captain, distinguishing himself by his bravery and coolness in several severe engagements. He rendered efficient services in bringing off the troops after the ill-fated expedition to Ticonderoga under Lord Howe in 1758, and was actively employed in the subsequent campaign of Gen. Amherst; and in 1760, the war being virtually closed, he retired from the service, and was not again conspicuous until the outbreak of the revolution. In 1775, on receipt of the intelligence of the beginning of hostilities, he hastened to Boston after directing the volunteers in his neighborhood to rendezvous at Medford. Of those who followed him two regiments were formed, of one of which he was elected colonel, and at its head he thrice repulsed the veteran forces of the British army at Bunker hill. He afterward remained with his regiment at Winter hill until the British evacuated Boston in March, 1776. He was in the expedition against Canada, and remonstrated against Gen. Schuyler's retreat to Ticonderoga. In December he marched with his regiment under Gen. Gates to reinforce Gen. Washington. He led the van in the attack upon Trenton, and was in the battle at Princeton. In 1777, the time of his regiment having expired, he returned to New Hampshire and raised a new one; but being as he thought unjustly neglected by congress in the list of promotions, he retired from its service. He however received a vote of thanks from the New Hampshire legislature, and in a short time was placed in the independent command of the troops raised by New Hampshire to oppose the British advance from Canada. Acting upon the authority of the state and his own judgment, he firmly refused to obey the orders of Gen. Lincoln to march to the west of the Hudson, leaving Burgoyne's rear unmolested; and on Aug. 16, 1777, he fought the battle of Bennington, killing over 200 of the enemy and taking 600 prisoners and 1,000 stand of arms. For this brilliant action congress passed a vote of thanks to him and created him a brigadier-general, notwithstanding they had just previously passed a vote of censure for his disobedience of the orders of Gen. Lincoln. He joined Gen. Gates at Bemus's heights, but the term of his militia having expired, he was obliged to return to New Hampshire and recruit a new force, with which he cut off Burgoyne's retreat from Saratoga, and thus compelled him to surrender. In 1778 he was placed in command of the northern department; in 1779 and 1780 he served in Rhode Island and New Jersey, and at West Point, where he was a member of the court martial which condemned André; and in 1781 he again had command of the northern depart-

ment, with his head-quarters at Saratoga. At the close of the war he retired to private life, and was not again connected with public affairs. With the exception of Sumter, he was the last surviving general of the revolution at the time of his death.—See "Life of John Stark," by Edward Everett, in Sparks's "American Biography," 2d series, vol. i.

STARLING, or STARR, the common name of the coriostoral birds of the family *sturnida*, and sub-family *sturnina*, of which the genus *sturnus* (Linn.) is the type; the family also includes the straight-billed birds like the grackles, oxpecker, red-winged blackbird, and satin bower bird, described in separate articles. In *sturnus* the bill is long, straight, and sharp, with flattened culmen and tip; wings long and pointed, with 1st quill spurious and 2d and 8d nearly equal; tail short and nearly even; tarsi strong and broadly scaled; toes long, including the hind one, the outer united at the base; claws long, curved, and sharp. In habits the starlings resemble the smaller species of the crow family, and the food consists of worms, snails, insects, seeds, and fruits; they are docile in captivity, and may be taught to repeat a few words and to whistle short tunes. They are confined to the old world, migrating in large flocks, preferring swampy places; the flight is rapid and even, accompanied toward evening by singular circular evolutions; the note is a shrill whistle, with an occasional chatter or imitation of the cry of other birds and of animals; the nest is made of dried grass, in holes of trees or old buildings, and the eggs are 4 to 6. The best known species is the common starling (*S. vulgaris*, Linn.), about 8 inches long, of a black color, with purple and greenish reflections, and spotted with buff; the female is much less brilliant, and the young males are brownish gray. This well known, handsome, and sprightly bird is found from N. Europe to S. Africa, and in E. Asia, occurring in as large flocks as the allied grackles (*quiscalus*) in North America; in England it often migrates south in October, returning in March; it is frequently kept in cages; the flesh is disagreeable; the eggs are pale blue.—The American starling (*sturnella ludoviciana*, Swains.) has been described under MEADOW LARK. In the genus *pastor* (Temm.) the bill is shorter and more curved; it contains about a dozen species in the old world, with the habits of the preceding genus, also the one of seeking insects on the backs of cattle. The rosy starling (*P. roseus*, Temm.) is about 8 inches long, with the head, neck, quills, and tail black with violet gloss, and the rest of the plumage delicate rose-colored; the head is crested, and the bill and legs yellowish. It is found in S. E. Europe, and in the warm parts of Asia and Africa; in some places it is held in great veneration for the enormous quantity of noxious insects, especially locusts, which its flocks devour.

STARR, a S. co. of Texas, bounded S. W. by the Rio Grande, which separates it from the Mexican state of Tamaulipas; area, 4,420 sq.

m.; pop. in 1860, 2,406, of whom 6 were slaves. It is well adapted to grazing and to the cultivation of cotton, corn, and sugar cane. Large droves of wild horses are found on the prairies. Capital, Rio Grande City.

STARVATION. See ABSTINENCE.

STASSART, GOSWIN JOSEPH AUGUSTIN, baron, a Belgian statesman and author, born in Mechlin, Sept. 2, 1780, died in Brussels, Oct. 16, 1854. He completed his education in Paris, and was appointed successively intendant in the Tyrol (1805), successor of Bignon in Berlin (1808), and prefect of the department of the Bouches de la Meuse (1811). He took part as an officer of artillery in the defence of Paris (1814), offered his services to the emperor of Austria after the first restoration, attached himself again to Napoleon as envoy to Austria and master of requests during the Hundred Days, and on the second restoration retired to Namur and devoted himself to literary studies. He represented Namur in the second chamber at the Hague from 1821 to 1830, and supported the opposition. After the Belgian revolution of 1830, he was appointed governor of the provinces of Namur and Brabant, was president of the senate from 1831 to 1838, was sent as envoy extraordinary to the court of Turin in 1840, and lived in retirement from 1841. His writings, including *Idylles* (1800), *Pensées de Virce* (1814), *Fables* (1818), and treatises on agriculture and archaeology, were collected by Dupont-Delporte (Paris, 1855).

STATEN ISLAND. See RICHMOND CO., N. Y.

STATIOS. See MECHANICS.

STATISTICS, the science which has for its office the collection and arrangement of facts relative to the physical, social, political, financial, intellectual, and moral condition and resources of a state or nation. Some departments of statistical knowledge are of very ancient origin. No nation has made any considerable advance toward civilization, which has not at stated periods taken a census more or less complete of its inhabitants. That such statistical records were kept by the Jews, the Greeks, and the Romans, there is abundant evidence. In later times, the first writer on statistics was the Venetian doge Tommaso Mocenigo, who in 1421 collected the materials for a memoir on the situation of different empires, their monetary systems, finances, public debts, &c. In 1467 Francisco Sansovino published a statistical work entitled *Del governo e amministrazione di diversi regni e repubbliche* (4to., Venice, 1467), which was translated into several languages and often reprinted. During the next century Ventura, Paruta, and Giovanni Botero, all Italians, wrote on the subject. Botero's *Relazioni universali* (Rome, 1592) was translated into most of the languages of Europe. Pierre Davity, a French writer, published in 1621-2 a valuable work on the geography, government, finances, religion, and customs of the principal countries of the world.

Hans de Laet in 1624 commenced the publication in Holland by the Elzevirs of his "Republics," a series of statistical works, and was followed during the 17th century by Conring, Boese, Beckmann, and Gastel in Germany, by De Luca and Everard Otto in Holland, and by Oldenburg in Switzerland, whose *Thesaurus Rerumpublicarum* (4 vols. 8vo., Geneva, 1675) was an excellent compilation of statistical matters. In 1749 Gottfried Achenwall delivered lectures on statistics in the university of Göttingen, and gave the name (Ger. *Staat*, state) to the science. Conring, it is stated, had lectured on the subject nearly a century before; but Achenwall systematized it, and prepared a treatise for the use of the students of the university (*Staatsverfassung der Europäischen Reiche im Grundriss*), which passed through 7 editions in the next 50 years. Walch and Reinhard also published text books on the subject, soon after, for their respective universities. A student of Achenwall, Professor Schlözer, developed the science more fully than his teacher, but died before his great work, "Theory of Statistics" (Göttingen, 1804), was completed. In England, the first statistical work of note was by Smollett, who published "The Present State of all Nations" (8 vols. 8vo., London, 1768). Gatterer (Göttingen, 1773), Niemann (Altona, 1807), and Leopold Krug (Berlin, 1807) have written able works on the science. Luden (Göttingen, 1812 and 1817) has been one of its most vehement assailants. Among the statistical writers of the present century, those who occupy the first rank are Melchior Gioja, the author of *Nuovo prospetto delle scienze economiche* (6 vols. 4to., Milan, 1815-'19) and *Filosofia della statistica* (2 vols. 4to.); Hassel, *Lehrbuch der Statistik der Europäischen Staaten* (4 vols., Weimar, 1812-'18), and several other geographical and statistical works; Stein, *Manuel de géographie et de statistique* (3 vols. 8vo., Leipsic, 1833); Schubert, professor at Königsberg, *Staatenkunde von Europa* (6 vols., Königsberg, 1835-'45); Meusel, *Literatur der Statistik* (2 vols., Leipsic, 1806-'7); Malchus, *Statistik der Staatskunde* (Stuttgart, 1826); Schnabel, a Bohemian writer, *Statistique générale des états Européens* (2 vols. 8vo., Prague, 1829); Herbin and Penchet, *Statistique de la France* (7 vols., Paris, 1803); Adriano Balbi, various comparative statistical works on Portugal, France, Russia, the British empire, &c. (Paris, 1822-'9); Berghans, author of *Allgemeine Länder- und Völkerkunde*, of *Staatenkunde*, and numerous other works, and editor of *Annalen der Erd-, Völker- und Staatenkunde* (1830-'43), *Geographisches Jahrbuch*, and other periodicals; Becker, author of numerous works on Austrian statistics; Dieterici, chiefly on the statistics of Prussia and the Zollverein; Charles Dupin, *Forces productives et commerciales de la France* (2 vols. 4to., Paris, 1832), and other works; J. H. Schnitzler, *Essai d'une statistique générale de l'empire de Russie* (Strasbourg and St. Peters-

burg, 1829), and *Statistique générale, méthodique et complète de la France* (4 vols. 8vo., Paris, 1842-'6); Maurice Block, *Statistique de la France* (2 vols. 8vo., Paris, 1860); J. R. McCulloch, the author of many statistical works in English of great value; John McGregor, "Commercial Statistics" (5 vols. 8vo., London, 1848-'50), and other works; the Rev. John Olay, author of several works on prison statistics; Léon Faucher, author of numerous statistical contributions to the *Journal des économistes*; W. Newmarch, editor of the "Journal of the Statistical Society;" and in the United States, T. Pitkin, A. Seybert, J. S. Fisher, J. D. B. De Bow, Freeman Hunt, Dr. J. Thomas, Dr. J. Chickering, T. P. Kettell, J. S. Homans, J. C. G. Kennedy, Dr. J. G. Osgood, and Dr. Edward Jarvis.—Within a few years past, societies for the collection of statistics have been established in most of the countries of Christendom. The statistical society of London was founded in 1834, and has since 1837 published a quarterly journal. The Parisian society commenced in 1842 the publication of a monthly periodical, the *Journal des économistes*, which has a deservedly high reputation. In the United States there is a genealogical and statistical society at Boston, which published for some years a quarterly "Register;" a geographical and statistical society at New York, which issues a quarterly "Bulletin;" and several periodicals devoted in part to special statistics, such as the "American Journal of Science and Arts," the "American Journal of Education," the "Merchants' Magazine," the "Bankers' Magazine," "De Bow's Commercial Review," the "Mining Magazine," and the "United States Insurance Gazette and Magazine." The British association for the advancement of science has had a statistical section since 1838; the American association has a similar section; and the encouragement of the collectors of statistical matters is one of the avowed means by which the Smithsonian institution proposes to diffuse knowledge among men.

STATIUS, OECILIUS. See OECILIUS STATIUS.

STATIUS, PUBLIUS PAPINIUS, a Roman poet of the time of Domitian, whose birth has been placed in A. D. 61, and death in A. D. 96, though there is only uncertain evidence for either statement. His father was a preceptor of Domitian, by whom the son was patronized. In the Alban contests he 3 times gained the victory. Juvenal is the only ancient author who mentions him (*Satire* vii. 82). It has been stated, but without good evidence, that he was a Christian, and that the emperor stabbed him with a *stilus* in a moment of anger. His extant works are: *Silvarum Libri V.*, a collection of 82 poems on passing events, divided into 5 books; *Thebaidos Libri XII.*, an epic poem, founded upon the legendary account of the expedition of the Seven against Thebes, of which the 1st book was translated into English by Pope; and *Achilleidos Libri II.*, an epic poem never finished. There are no

good editions of Statius, the best being that found in Lemaire's series of Latin classics (4 vols. 8vo., Paris, 1825-'30). Five books of the "Thebaid" have been translated into English by Thomas Stephens (8vo., London, 1648), and the entire poem by W. L. Lewis (2 vols. 8vo., Oxford, 1767 and 1773). The "Achilleid" has been translated by Howard (8vo., London, 1660).

STATUARY. See **SCULPTURE**.

STATUTE OF FRAUDS. See **FRAUDS, STATUTE OF**.

STATUTES OF LIMITATION. See **LIMITATION, STATUTES OF**.

STAUDENMAIER, FRANZ ANTON, a German theologian and philosopher, born at Danz-dorf, Württemberg, Sept. 11, 1800, died in Freiburg, Baden, Jan. 19, 1856. He studied at the university of Tübingen, and was ordained a Roman Catholic priest in 1827. In 1828 he was appointed tutor in the theological seminary at Tübingen, in 1830 ordinary professor of theology in the newly created theological faculty of the university of Giessen, in 1837 ordinary professor in the university of Freiburg, and in 1848 also a canon of the cathedral church of that city. In 1851 he was elected a member of the first chamber of the legislature of Baden. His first work was a "History of the Election of Bishops" (*Geschichte der Bischofswahlen*, Tübingen, 1830), with particular reference to the rights claimed by Christian princes. His *Encyklopädie der theologischen Wissenschaften* (Mentz, 1834; 2d ed., 1840) is the only German work of the kind in Catholic literature. His work on the "Spirit of Christianity" (*Der Geist des Christenthums*, Mentz, 1835; 5th ed., 1855) has had a very extensive circulation, and has been translated into several foreign languages. The most important of his works is that on "Systematic Theology" (*Die christliche Dogmatik*, 4 vols., 1844-'52; not complete), in which he attempts to harmonize the results of modern philosophy with the doctrines of the Catholic church. His other principal works are: *Scotus Erigena und die Wissenschaft seiner Zeit* (vol. i., Frankfurt, 1840; not completed); *Die Philosophie des Christenthums* (vol. i., Mentz, 1840; not completed); *Darstellung und Kritik des Hegelschen Systems* (Mentz, 1844); and *Der Protestantismus in seinem Wesen und seiner Entwicklung* (Freiburg, 1846). Staudenmaier has also been a contributor to journals of Catholic theology, and to the Protestant "Journal for Philosophy and Speculative Theology," edited by Fichte.

STAUDLIN, KARL FRIEDRICH, a German theologian, born in Stuttgart, July 25, 1761, died in Göttingen, July 5, 1826. He studied theology and philosophy at the university of Tübingen, from 1786 to 1790 made several literary journeys through Germany, Switzerland, France, and England, and was appointed in 1790 professor of theology at the university of Göttingen, where in 1803 he was also made consistorial councillor. In his earlier years he

was a rationalist, but he gradually inclined to supernaturalism. His works are very numerous, and extend over nearly every department of theology; but those on church history are the most valued. Among them are: *Kirchliche Geographie und Statistik* (2 vols., Tübingen, 1804), the first scientific work on this subject; and *Geschichte der theologischen Wissenschaften* (2 vols., Göttingen, 1810-'11). He was also the editor of several theological journals.

STAUGHTON, WILLIAM, D.D., an American clergyman, born in Coventry, Warwickshire, England, Jan. 4, 1770, died in Washington, D. C., Dec. 12, 1829. At the age of 17 he published a small volume of "Juvenile Poems," and soon afterward entered the Bristol Baptist seminary to prepare for the ministry. He emigrated to South Carolina in 1798, and preached for nearly 17 months at Georgetown, S. C. In 1795 he removed to New York, and in 1797 took charge of an academy at Bordentown, N. J., and was ordained. Toward the close of 1798 he removed to Burlington, N. J., and in 1805 became pastor of the first Baptist church of Philadelphia, which increased so much under his ministry that its house of worship was several times enlarged, and three new churches were formed from it. With the last of these, the Sansom street church, Dr. Staughton identified himself, and continued there till 1823, preaching from 8 to 4 times every Sunday to audiences of several thousands, and 2 or 3 times during the week, and at the same time instructing 15 or 20 young men in theology, lecturing on botany, chemistry, and sacred and profane history in two female seminaries, editing wholly or in part two religious periodicals, and presiding or assisting at the meetings of numerous benevolent societies. In the autumn of 1823 he became president of Columbian college at Washington, D. C., which position he resigned in 1827, in consequence of the embarrassments of the college, which he had made extraordinary efforts to remove. He then returned to Philadelphia, and was soon afterward chosen president of the Baptist college and theological institution at Georgetown, Ky., but died on his way thither. He published little beside his numerous contributions to religious periodicals in prose and poetry, and 5 or 6 sermons and orations.

STAUNTON, a river in the S. part of Virginia, rising in Montgomery co., among the Alleghany mountains, flowing E. and S. E. through a pass in the Blue ridge, and with Dan river forming the Roanoke at Clarksville, Mecklenburg co. It is 200 m. long, and in the first 20 m. of its course has a fall of 1,000 feet.

STAUNTON, a town and the capital of Augusta co., Va., situated on a small tributary of the Shenandoah river, 120 m. W. N. W. from Richmond; pop. in 1850, 2,500; in 1860, 14,124. It is the oldest town in the valley of Virginia, having been incorporated in 1749, and is the seat of the western lunatic asylum and of the Virginia institution for the deaf and

dumb and the blind. It has 2 weekly newspapers, 10 or 12 churches, several banks and banking houses, 2 academies, and 2 seminaries. It is surrounded by a populous and rich agricultural region, and has an important local trade. There are mills, founderies, and manufacturing of various kinds. The Virginia central railroad passes through it, and it is the proposed terminus of the Manassas Gap railroad, partially completed.

STAUNTON, SIR GEORGE LEONARD, an English diplomatist, born in Galway, Ireland, April 19, 1737, died in London, Jan. 14, 1801. He studied medicine and became a contributor to literary periodicals, and an intimate acquaintance of Dr. Johnson. He afterward held official position and practised medicine in the West Indies for several years. In 1774 he was attorney-general of Grenada, and when that island was taken by the French in 1779, he and Lord Macartney, the governor, were made prisoners, but were soon released and returned to England. In 1781 he went as confidential secretary of Lord Macartney to Madras. He made an advantageous treaty with Tippoo Sultan in 1784, for which he was raised to a baronetcy and received an annuity of £500 from the East India company. He was a member of Lord Macartney's embassy to China in 1792, of which he published an account (3 vols. 4to., 1797).—SIR GEORGE THOMAS, an English author, son of the preceding, born in Salisbury, May 26, 1781, died in London, Aug. 10, 1859. He accompanied his father to China in 1792, entered the university of Cambridge on his return to England, and in 1799 went to Canton as secretary of the East India company's factory there, of which he afterward became president. In 1816 he was attached to Lord Amherst's embassy to China, and from 1818 to 1852, with a few intermissions, was a member of parliament. His principal works are: "The Penal Code of the Chinese Empire" (4to., London, 1810); "Narrative of the Chinese Embassy to the Tartar Khan Tougouth during the Years 1812-15" (1821); and "Miscellaneous Notices relative to China and the British Commercial Intercourse with that Country" (1822). A treatise on vaccination written by him in Chinese was the means of introducing its practice in some parts of the empire. He edited the "History of the Great and Mighty Kingdom of China," translated from the Spanish of Mendoza by Parke in 1838 (Hakluyt society, London, 1858).

STAUPITZ, JOHANN VON, the friend and patron of Luther, born at Meissen, died in 1524. He entered in early life the Augustinian order, obtained from the pope in 1501 general privileges for the newly established university at Wittenberg, and in 1508 by his influence caused Luther, a member of his order, to be called to one of the professorships. Luther gratefully acknowledges that in his spiritual struggles he found in Staupitz a kind adviser and guide. Staupitz

approved of the theses of Luther against the papal indulgences, though he did not publicly declare himself in favor of them. In 1518 he was with Luther at an assembly of his order at Heidelberg, and in the same year demanded at Augsburg that Luther should not be condemned unheard and untried. Soon after, however, fearing an adverse issue of the controversy, he withdrew to Salzburg, where he became court preacher, and in 1522 abbot of a Benedictine convent. Whether, as some assert, he was shortly before his death bishop of Oheimsee, is doubtful. He is the author of two works, *De Amore Dei* and *De Fide Christiana*, in which a mystic tendency prevails.

STEALING. See LARCENY.

STEAM, the name applied generically to the vapor or non-permanent gas given off by any liquid, in consequence of the volatility of such liquid and the influence of heat upon it; and more especially when the vaporization takes place at temperatures at or above the boiling point of the substance so affected. In the recent progress of mechanical art and science, however, this term has come to designate in a specific sense the vapor of water, as applied or applicable to the performance of work, or to other mechanical or economic purposes. In connection with this subject see BOILING POINT, EVAPORATION, HEAT, and PNEUMATICS. In popular language, the visible mist forming when a vapor is discharged into the air, as a little way from the spout of a boiling kettle, or in a dense cloud above an engine "blowing off" steam, is also called steam. This visible mist is, however, really of the nature of cloud; being probably a collection in immense numbers of minute vesicles formed of water condensed from the vapor, and also enclosing vapor or air, and which, disseminated in the atmosphere, constitute an opaque and visible mass, in the same way as do the fine globules of a transparent oil when the latter is beaten up and mingled through water. Steam, properly so called, is perfectly transparent and colorless, as are the greater number of gases of all sorts; and hence it is always wholly invisible. Whenever a confined body or other volume of steam seems to become visible, the truth is that a portion of the vapor is condensed into water in fine drops, or in a haze or cloud; and though there may also be steam occupying the space through which this is diffused, it is the water or cloud only that is seen. The engineer and the general reader have thus alike to bear in mind that, in dealing with steam (proper), they have to do with a gaseous body which eludes the sight as completely as the purest atmospheric air. Perfect steam is, moreover, in no way moist, but is dry, as are the permanent gases; the moisture sometimes showing upon a solid surface it touches, or that has been plunged into it, being due to condensation. With such slight exceptions as are hereafter to be noted, steam has in a complete degree those properties of fluidity, mobility, elasticity, and equality of pressure in every

direction about any point in a volume of it at rest, that distinguish the gases; and in consequence of which it is brought under the ordinary laws of pressure, equilibrium, and movement of gaseous fluids, as given in the article *PNEUMATICS*. At the same time, the rapidity with which, at a given condition and temperature, it can be condensed, or again formed, and the great disturbances in its heat and elastic force or pressure that occur at the moments of such changes, strikingly distinguish it from the permanent gases, and in fact impart to it its peculiar fitness as a medium through which to apply the motive power of heat.—It will be remembered that the agency we call heat exists free in all bodies upon and about our globe; and that, whenever in any body or space an excess of this free heat is in any way caused to appear, as by combustion of wood or coal, or the action of the sun's rays, this excess at once tends to be imparted to and equalized throughout surrounding bodies and spaces, at such rates as the nature of the latter, their surfaces, &c., will allow; while, if at any place a reduction of heat occurs, the surrounding bodies and spaces impart heat to this, and again with a rapidity depending on their nature and the character of the surfaces separating or bounding them. Now, between the particles of all fluids there is acting at all times a repulsive force or energy, greater or less, tending to drive the particles asunder; if the body be a liquid, to throw it into the gaseous condition; if a gas, to enlarge still further its volume. It is this repulsive energy that, as we pump off the surrounding atmosphere from about a tight bladder holding a little air and placed in the receiver of an air pump, goes on distending the bladder, till it may even burst it from within outward. The repulsive action in these bodies is moreover known to be either directly that of heat, or such as heat directly conspires with and augments. And as the small body of air confined in the bladder is, in the atmosphere, kept by pressure of the surrounding air within a moderate volume, so it is found also that a vast number of liquids—those termed volatile—at any ordinary temperatures owe their liquid state to the superincumbent pressure of the atmosphere upon their surfaces. Water is, for all temperatures above its freezing point, a perfectly volatile liquid; so that if we should introduce a pint of it, at any temperature from 212° down to 32° , into a perfectly vacuous space large enough to contain the resulting perfect vapor, the whole of the liquid would vaporize instantly and disappear in the gaseous form. The only other condition necessary to this result is, that the bodies in contact with the liquid when introduced shall be able to yield to it a sufficient amount of heat to convert it as stated; this heat becoming latent in the vapor, and the bodies parting with it becoming correspondingly cooled. In so vaporizing the water, also, as the temperature taken for the change was lowered, the vapor itself when

formed would have a feebler elastic tension, and would be less dense; so that a larger vacuous space must be continually provided as we approach 32° , to insure the rapid and complete volatilizing of the liquid. But if into the vacuum some air were introduced, and the experiment repeated, the vaporization of the liquid would be retarded, and more—finally even to nearly preventing it altogether—as the density and pressure of the admitted air were increased. This repressive effect of the incumbent air, however, could always be overcome by artificially applying a sufficient degree of heat to the liquid. And when the atmospheric pressure equalled its average at the sea level, 14.7 lbs. avoirdupois to the square inch of surface, if heat sufficient could be supplied, any quantity whatever of water would still vaporize and become steam instantly, against and in spite of such pressure, at the moment when the temperature of the entire liquid mass became raised to 212° . Thus, while evaporation takes place slowly at all temperatures, down to and below zero of Fahrenheit, giving vapor of feebler tension and less density—the tension at 0° equaling $\frac{1}{18}$ inch of mercury—a vaporization of whole volumes of liquid (larger or smaller, according to the facility with which the requisite heat can be supplied to enter into the latent form, or give to the resulting vapor its tension) must commence in any body of water or other liquid so soon as the tension of its vapor is made equal to the pressure of air or other gaseous bodies upon the surface of the liquid. It is this tumultuous vaporization that we call boiling; its rate being really slow, and the process prolonged, only (and fortunately, in view of the risk otherwise of continual explosions) by reason of the fact that but a limited and gradual supply of heat can, under any circumstances, be made to enter the liquid. The principal fact here, and the one never to be lost sight of, is, that any liquid in ordinary conditions vaporizes in volumes, *i. e.*, boils, at the precise moment when the tension of its vapor due to heat has risen to an equality with the pressure of that atmosphere, whether of common air, or of confined vapor already formed, which rests or presses upon its surface. And no matter how the vapor forming is in the main enclosed, if there be but one small aperture in the boiler, the cylinder, or other passages, through which the atmosphere without can transmit its pressure, and any excess of vapor within above that pressure can escape, it is still the atmospheric pressure precisely that acts upon the liquid surface. Hence it is seen that, the character of the vessel and other conditions being like, and the incumbent pressure the same, the temperature of ebullition of the liquid remains always the same; that under a given pressure the temperature of the liquid remains constant through the whole period of the ebullition, a greater quantity of heat communicated to the liquid having only the effect to evolve during a given time a larger volume of steam; that

the elastic force or tension of steam forming at 212° F. is precisely equal to the weight of the superincumbent atmosphere, or very nearly 14.7 lbs. per square inch; and that when, by confining the vapor obtained, its density and pressure are increased, a higher temperature becomes necessary to secure ebullition, and we say that the boiling point is raised. Steam forming by boiling at 212° is thus said to have a tension or pressure of 1 atmosphere; at 284° , of $1\frac{1}{2}$ atmospheres; at 250° , 2; at 264° , $2\frac{1}{2}$; at 274° , 3; at 292° , 4; at 306° , 5; at 340° , 8; at 357° , 10; at 389° , 15; and at 415° , 20 atmospheres, or about 294 lbs. per square inch. Generally, as produced over or in communication with water of its own temperature at the moment of its formation, steam is at its maximum of density for the temperature, whatever that may be. Under such circumstances, however, the steam mass owes a part of its actual density to the holding of more or less of finely divided water or mist in suspension through it. In whatever its density may consist, the greatest pressure under which steam can exist at a given temperature, as steam, is also the least pressure under which water similarly heated can retain the liquid form. This is called, for the given temperature, the pressure of saturation; and the steam is said to be saturated. On the other hand, steam refuses to generate freely or in volumes with less than this maximum quantity of vapor. That is, steam and water thus conditioned are, so to speak, at an equipoise; increase of heat will increase the quantity of water vaporized, and so, in a confined space, the density of the vapor; or increase of pressure will compel a portion of the vapor already formed to resume the liquid state. The steam stands, at the same moment, at the condensing point and at the generating point; and in fact, throughout the entire range of heat, there will occur at every point, in unalterable conjunction, one density, one pressure, and one temperature; and always, the density being given, the other elements will correspond. Of course, when change in one of these particulars occurs, slight lapses of time must be allowed the others to adjust themselves to this; but the agreement of all the conditions just expressed is that to which the steam mass communicating with the water in the boiler is always tending. If from steam under more than one atmosphere of pressure, and the temperature and density of which are proportionally increased, some heat be withdrawn, the tension and hence the density fall, and part of the steam resumes the state of water. If, while the temperature remains constant, the space or volume over the water be increased, then, so long as there remains an excess of liquid to supply fresh vapor for the augmented space, the density and tension will not diminish, but remain constant at the maximum due to the given temperature. If, after all the liquid is evaporated, heat be not added to the steam mass, but the space or volume be enlarged, the steam expands, and its

density and pressure diminish, as in the permanent gases. If, then, the volume be again reduced, the density and pressure increase, until they return to the maximum due to the temperature, reaching the condensing point; and the effect of further diminution of volume must be precipitation or liquefaction of corresponding quantities of the vapor, the density remaining constant, and even until the whole mass of vapor had thus been forced back to the liquid condition. If, after all the liquid is evaporated, or a portion of it has been separated in any way from the water surface, the application of heat be continued, the state of saturation is left behind; and even if the same density be preserved, the tension or pressure is increased, though not so rapidly as if with the same increase of temperature the steam could remain in contact with the water, and so continue to maintain through this rise the condition of saturation. The steam so separated and heated loses the moisture which may accompany it in the saturated state, and at a few degrees of added temperature acquires in full the character of a perfect gas; it is then said to be surcharged with heat, and it is known as gaseous or subsaturated steam, more commonly as "superheated steam," and is by some writers termed "stame." Let steam in this condition be replaced in contact with the water in the boiler, or in any way brought into free communication with it—the water having yet the original temperature—and such steam would immediately evaporate and absorb a further portion of the water, transferring to this its excess of heat, and would become saturated, its temperature falling to that of the water.—The relation, generally, of heat to the production of mechanical effect, or work, is considered under HEAT. The unit is the mechanical equivalent of the heat required to raise through 1° F. 1 lb. of water; and this, experiment seems to show, is 772 lbs. weight raised against gravity through 1 foot of height, i. e., 772 foot-pounds. If 1 lb. of water at 212° be injected into a vacuum space of 26.36 cubic feet—this being the volume of 1 lb. of saturated steam at that temperature—and if it be evaporated into such steam, there will be expended in the process 892.9 units of heat. Now let a second pound of water at 212° be injected into and evaporated in the same space; and this, having to assume its volume or advance against a pressure of 14.7 lbs. per square inch, will perform work to the amount of $26.36 \times 144 \times 14.7$ lbs. = about 55,800 foot-pounds; and since $\frac{44000}{772} = 72.3$, this quotient will be the number of additional units of heat that must in such case be consumed or expended in displacing the first steam atmosphere, against which the second must advance; so that to convert the second pound of water into steam against this pressure will require 965.2 units of heat. When steam flows from the boiler into vacuum space, without performing work, its temperature, chiefly by reason of its friction against the

edges or sides of the passages it moves through, is considerably raised. But if, in so expanding, it must meanwhile perform the work of lifting or pushing a piston or other movable load, the theory requires that in so doing it shall lose a corresponding portion of heat, and that, if it were before at the point of saturation, by the cooling that results a portion of the steam shall return to the liquid form; and it is believed that practical observations and tests confirm this result of the thermo-dynamic theory.—From the known rate of expansion of perfect gases, it is inferred that were a given volume of a gas, as air, for example, continually cooled, its volume would uniformly diminish; and that at -461.2° F., or 493.2° below the freezing point of water, it must wholly collapse, its elasticity and volume becoming 0. This point, then, -461.2° , is considered as the “absolute zero” of heat; and temperature reckoned from it is “absolute temperature.” If a given volume of air, under a constant pressure, be heated from 0° F. through 461.2° , its volume is doubled; heated through 2×461.2 , its volume is tripled; and universally, the volume is augmented $\frac{1}{461.2}$ part for every addition of 1° of heat. This expression also gives the rate of expansion or contraction for superheated steam. For the permanent gases and for superheated vapors, then, the laws respecting volume and pressure may thus be briefly stated: 1, the temperature remaining constant, the tension or pressure varies inversely as the volume; 2, the pressure constant, the volume varies directly as the absolute temperature; 3, the volume constant, the pressure varies directly as the absolute temperature. Now, omitting for the moment any effect of specific heat, the amount of heat that must have entered, in vaporizing it, a pound of water vapor, will be found to consist always of two readily distinguishable parts: first, the whole amount of the heat required to raise the liquid, before evaporation takes place, from some fixed temperature to that of the evaporation, i. e., the “sensible heat;” secondly, the whole amount of the heat which disappears in the process or work of converting the pound of water already at its evaporating point into vapor, i. e., the latent heat of evaporation. In reckoning the sensible heat, it is not necessary to start from the absolute zero; and as the most convenient point, and one sufficiently low to underlie all ordinary calculations about steam, 32° is adopted as, for these cases, the 0 of the sensible temperatures considered. The sum of these two parts of the heat contained in steam, the sensible reckoned from 32° , and the latent of evaporation, is termed the total heat of evaporation, or total heat of steam. As the sensible heat is very readily and nearly determined in all cases, it has been, ever since the complete development of the capacities of steam mechanism by the inventions of Watt, an important problem to ascertain precisely the amount and rate of variation of the latent heat of the vapor. The estimates arrived at, for the

latent heat of 1 lb. of water at 212° , have varied from that of Dr. Black, at 810° , to those of Count Rumford, 1050.5° , and of the committee of the Franklin institute, Philadelphia, 1037° . (For details of apparatus and methods in these, as well as in the experiments of Regnault, see the works of Tredgold and Bourne on the steam engine.) It was during such researches, also, that the supposed laws of Watt and of Southern were arrived at; the former that “the total quantity of heat necessary to vaporize a given weight of water was the same at all sensible temperatures,” the latent heat diminishing as the sensible heat was raised; the latter, conflicting with that of Watt, and still more erroneous, that “the latent heat of vaporization was the same under every degree of pressure.” In Regnault’s experiments and calculations, probably conducted with the utmost attainable precaution and accuracy, the total heat of evaporation at 0° C., $= 32^{\circ}$ F., was determined as equal to 606.5° C., $= 1091.7^{\circ}$ F. He also found that, between 0° and 230° C., the total heat of saturated steam increases (a slight change in specific heat being here disregarded) uniformly by $.305^{\circ}$ for each added degree of heat. This result also determines the specific heat of ordinary steam as .305, that of water being 1. Letting t represent the indicated temperature in any case, and conforming the expression to the observed total heat at 212° , Regnault’s formula for total heat at all temperatures, in degrees F., is $H = (1118.4 - 32) + .305t$; or, $H = 1086.4 + .305t$; so that the total heat of saturated steam at 212° is 1146° F. This is the total consumption of heat if the water be supplied at 32° . When the water is supplied at temperatures above this, for 32 in the formula substitute the given temperature. Thus, taking cold water at average temperature, $H = (1118.4 - 62) + .305t$; or, $H = 1056.4 + .305t$. If, as in condensing engines, the water be at 100° , then $H = 1018.4 + .305t$. If the water be supplied at boiling point, allowing $.9^{\circ}$ for specific heat, then $H = (1118.4 - 212.9) + .305t = 905.5 + .305t$. And converting the formula given by Clausius for the latent heat of steam, we obtain in Fahrenheit’s scale, $L = 1115.2 - .708t$. Let it further be borne in mind that the same figures which above express in degrees the relations of the constituent heat of steam, in form of ratios merely, and not as absolute quantities, will also express positive values, in units of heat, if we assume the quantity of steam as 1 lb. weight, so as to accord with the requirements of the thermal unit. The appropriation of all the heat contributing to the formation of 1 lb. of saturated steam at 212° , and given both in units of heat and of work, will now be understood from the following tabular statement:

	Units of heat.	Mechanical equivalent, in foot-pounds.
A. The sensible heat:		
1. To heat the water from 32° , or through 180°	180.0°	= 180,655

B. The latent heat:

1. To convert the water to vapor, irrespective of pressure on surface
2. To advance against and remove the incumbent atmosphere, whether air or previously generated steam, its pressure being 2,116.8 lbs. per square foot of surface...

Units of heat. Mechanical equivalent, in foot-pounds.

892.9° = 699,243

72.8° = 55,815

Total latent heat 965.7° = 745,057

Total heat of steam 1,146.1° = 894,719

It becomes evident at the same time, that the total latent heat of steam cannot be taken as in any way the measure of the energy or work in, or that can practically be obtained from, the steam. Much the larger part of such heat is expended in merely overcoming the cohesion of the liquid; and at all temperatures, it is but a small fraction of the latent heat that can be made available in performing work.—Water at 212° and under one atmosphere, becoming steam, is ordinarily said to expand into a volume 1,700 times greater than that occupied by the water itself. The increase of volume is, however, always less than this, being differently stated at from 1,670 down to 1,642 times the original volume. It is remarkable that the uncombined oxygen and hydrogen gases composing the same weight of steam, at the same temperature and pressure, would occupy 2,500 times the volume of the water. Thus, the density and pressure of actual steam always exceed those which the ideal steam, or that on the supposition of a perfect gas, would exhibit. By means of recorded observations of experiments on steam, and finding the mean of the most trustworthy results, with the further aid of formulas and calculations, some of which are in this article intimated rather than detailed, very full tables of the properties of saturated and of superheated steam have been prepared. Of such a table for saturated steam, a brief abstract only can here be introduced.

TABLE OF PROPERTIES OF SATURATED STEAM.

Total pressure per square inch.	Temperature in degrees.	Total heat in degrees above 32°.	Latent heat in degrees.	Density, or weight per cubic foot.	Volume of 1 lb. of steam.	Relative volume, or No. of cubic feet of steam from 1 of water.
Lbs.	Fahr.	Fahr.	Fahr.	Lb.	Cubic feet.	Ratio of volume.

270	407.9	1,205.8	836.4	.5393	1.70	106
300	417.5	1,206.6	819.6	.6486	1.54	96

As in case of all gaseous bodies observable near their point of liquefaction, steam diminishes in volume and tension, and increases in density, more rapidly as it approaches near to condensation, than under like variations of pressure when it is heated much above that point; but the amount of such irregularity is not ascertained. The density of steam is expressed by the weight of a given constant volume, usually that of a cubic foot; its relative volume is the ratio of its actual volume to the volume of the water producing it. The density and relative volume of saturated steam have been determined with tolerable accuracy, by comparison of the quantities which experiments have furnished us, in connection with the elements of pressure, temperature, and latent heat.—**STEAM ENGINE. I. History.** The history of the steam engine is not the history, in full, of the discovery and application of the force of steam. The steam engine proper, first produced and patented by Watt in 1768-'9, is not yet (1862) 100 years old; but the more obvious properties of steam, and among them its expansive force, were understood and treated of, and mechanical effects by its agency produced, before the Christian era. In respect to the earlier experiments with steam, comparatively little is now known. Heron, in his "Pneumatics," about 280 B. C., describes three different, but simple contrivances showing mechanical effects of steam. No further advance is known to have been made until the 16th or 17th century of our era, when, through the impulse given by the new art of printing, the works of Heron and Archimedes were disseminated and much read, and an age scarcely second to our own for the great number and variety of its mechanical contrivances was entered upon. Blasco de Garay of Barcelona, in 1543, is said to have propelled a vessel of 200 tons by paddles, with "a water boiler, liable to burst;" a statement to be received with much hesitation. In 1601 Giambattista della Porta described in his "Pneumatics" an apparatus of his for raising water by a tube into a close vessel, in which a vacuum had been obtained by condensation of steam. In 1615 Solomon de Caus, a French engineer, published in his *Raisons des forces mouvantes* the statement that by fire water is dissolved into an air with such violence as to burst a closed copper ball containing a small quantity of it, and highly heated; and he described the propelling of a jet of water, by pressure on its surface in the vessel, of steam generated from it. In 1629 Branca, an Italian engineer, described a machine in which a wheel was driven round by the impulse of steam against vanes. The first engine in which steam was applied to the performance of useful work, seems to have been that invented by the marquis of Worcester, and described by him in his "Century of Inventions" (1663); his description, so far as it is intelligible, indicating that steam was generated alternately in two vessels, and by pipes

transferred and made to exert a pressure upon the surface of water in a third; the water was raised, as he tells us, continuously to a height of 40 feet, one vessel of the vaporized water being sufficient thus to elevate 40 times its volume of cold water. Cosmo, grand duke of Tuscany, relates that he saw one of these machines in use at Vauxhall in 1656. The separate boiler seems to have been the original part of this invention. Dr. Denis Papin, well known as the originator of "Papin's digester," experimented much on the production and force of steam from 1695 to 1707, and at the former date first devised and employed a piston within a cylinder, and under which a vacuum was produced by condensation of steam. His plan was not practically realized in any form. He had previously invented the safety valve for boilers. In 1698 Capt. Thomas Savery secured letters patent for a machine for raising water by steam. It consisted of two boilers and two receivers for the steam, with valves, and the needful tubes. One of the receivers being filled with steam, its communication with the boiler was then cut off, and the steam condensed by cold water outside it; into the vacuum thus formed the atmosphere forced the water from below, when the steam was again caused to press upon the surface of the water and drive it higher. This engine was extensively used for draining mines; and the water raised was, in some instances, made to turn a water wheel, by which lathes and other machinery were driven. Some of the earliest cotton mills of Lancashire were thus supplied with power. As Papin's machine involved great waste of time, so did Savery's a very considerable waste of steam in reheating the cooled receivers, and in heating at the first the surface of the water to be raised. In 1705 Thomas Newcomen, a smith, and John Cawley, plumber, of Dartmouth, along with Savery, patented an engine combining for the first time the cylinder and piston and separate boiler, doubtless deriving the former from Papin's plan. Steam was admitted beneath the piston, and condensation at first secured by application of cold water without the cylinder; the pressure of the atmosphere forced down the piston, and in so doing worked a pump rod for raising water attached at the opposite end of a rude working beam, actuated by the piston rod. Thus, this was really an atmospheric pumping engine. Through the accident of a hole in the piston, letting the cold water directly into the cylinder, they discovered the superior rapidity and effectiveness of such condensation, and substituted the cold jet into the cylinder accordingly. The valves were opened and closed by hand, until a boy named Humphrey Potter, to gain time for play, substituted an apparatus of catches and strings, thus making the engine automatic. The contrivance first used was very clumsy; and it was wholly removed by Henry Beighton, who in 1788 first worked the valves by a rod direct

from the beam. In the mean time, many attempts at producing other forms of steam mechanism were being made in England and on the continent. The most important of these in principle, because containing the germ of the non-condensing or high pressure engine, was that of Jacob Leupold, a German, who in 1725 fitted directly upon a large boiler two cylinders, the steam and the escape passages of these being alternately opened and closed by a four-way steam cock; and who introduced beneath the pistons steam of comparatively high pressure, which was made to act against the atmosphere, *plus* the work of pumping water by means of a beam and pump rod actuated by each of the pistons. As Newcomen's atmospheric engine became extensively introduced for draining collieries and mines, and was found to effect a great saving of expense, its capabilities were soon fully tested, and indeed exceeded, by the demand for its use. The cylinders were enlarged from 12 to 60 inches diameter, and the other parts in proportion; so that the engines became gigantic, and required for their construction a degree of skill then rarely possessed. At this juncture, 1765-'74, John Smeaton devised a succession of improvements in the atmospheric engine, and carried it to its utmost perfection. This was still called the "fire engine," being so named even in Watt's earlier memoranda and patents, and the improvements in it had thus far been empirical only; the force was exerted in but one direction; the total pressure could not exceed that which air exerts, and in fact always fell short of it, because the vacuum beneath the piston was far from complete; while the purposes to which such an engine could be applied were necessarily very limited. The improvement of the engine on scientific principles commenced with the labors of Watt, who, while repairing a model of Newcomen's engine, discovered its various defects, and began to devise the methods of remedying them. He reflected that, "in order to make the best use of the steam, it was necessary, first, that the cylinder should be maintained always as hot as the steam which entered it; and secondly, that when the steam was condensed, the water of which it was composed, and the injection itself, should be cooled down to 100°, or lower where that was possible." The means to these ends occurred to his mind in 1765; namely, the separate condenser, in which condensation of steam, effecting its removal from the cylinder, was to be secured by cold water surrounding or injected into the reservoir for the purpose, the accumulating water to be removed by a pump. It next occurred to him that the open mouth of the cylinder must allow the latter to be cooled by the air following the piston, and that consequently some of the steam next admitted must be condensed. He therefore proposed to "put an air-tight cover upon the cylinder, with a hole and stuffing box for the piston rod to slide

through, and to admit steam above the piston to act upon it instead of the atmosphere." To prevent cooling of the cylinder by the external air, he would surround this by a larger one, the "jacket," the interspace to be kept filled with steam, and would cover or clothe the whole with wood or other substance conducting heat poorly. Thus, we must credit to the marquis of Worcester the first successful application of steam pressure to use; to Savery the application of the vacuum due to condensation, though he did not foresee the true method, or the full value of its application; to Papin the piston for receiving and transmitting the force of air or steam within a cylinder; to Newcomen and Cawley the cylinder and piston independent of the boiler, as also the working beam, and the plan of internal condensation; to Beighton the successful introduction of automatic apparatus for the valves; and to Watt the separate condenser, saving the cooling of the cylinder and consequent waste of steam in reheating it, and the exclusion of air from the cylinder, with introduction of steam above the piston, changes which, with those that followed and grew out of them, rendered the engine at length practical, economical, and complete. This was still a "single-acting" engine; the steam pressure during the pushing down of the piston being that alone which took effect on the mechanism to be driven, and the only object of the subsequent admission of steam below being to return the piston to the top of the cylinder. This engine was also chiefly used for pumping and draining. It seems to have occurred to Watt, as early as 1769, that additional economy would be secured, especially, as he thought, in working light loads, by closing the steam pipe before the piston had descended the full length of stroke, thus saving the filling of the cylinder completely with steam of the initial density, and allowing the stroke to be completed by expansion of that already admitted, aided of course by momentum of the beam and piston. This principle he first applied in 1776 in an engine erected at Soho, but he published no account of it until on patenting this and certain other improvements in 1782; the variety he named the expansive engine. The first public announcement of benefit from expansive working of steam, however, was by Jonathan Hornblower, who in 1781 employed two cylinders, one larger than the other; the steam, of the boiler pressure, having first driven the smaller piston, was immediately transferred, and allowed to act during its expansion (of course with diminishing pressure) upon the increased area of the larger piston, the two cylinders being thus approximatively equal in power.

VOL. XV.—4

Watt's general patent, however, was judged to exclude this invention, and it did not at that time come into use. In the single-acting engine, one half the motion was still unaccompanied by useful effect; and the application of the force was ill adapted to impart any other than a simple reciprocating movement. Since the time of Savery, it had been an object of importance with inventors to convert this movement into one of revolution, as adapted to machinery; and Halls, Fitzgerald, Stewart, and others had contrived various means of effecting this change. Watt early conceived of the use of the common winch or crank for this purpose; it was patented, however, by Wasbrough, and then by Steed, in 1781. As Watt was at this time engaged in his invention by which the engine was to be made "double-acting"—the steam being admitted to press alternately, and in turn condensed, both above and below the piston—thus fitting it to impart revolution to a shaft, to wheel work, &c., he was obliged to resort to other methods to secure this part of his purpose, among them to the "sun and planet" wheel. The adaptation of the engine to the production of a rotary motion prepared the way for its employment as the prime mover of every kind of machinery. The specification of the double-acting steam engine, with several kindred improvements, was enrolled July 4, 1782; and in 1784 patents were secured for the "parallel motion," the throttle-valve, the governor, the indicator, &c.; as also for a form of locomotive engine, which however proved impracticable. Among the earliest of the double-acting or rotative engines produced for sale was the Albion mill engine, fig. 1; an inspection

FIG. 1.

allel motion," the throttle-valve, the governor, the indicator, &c.; as also for a form of locomotive engine, which however proved impracticable. Among the earliest of the double-acting or rotative engines produced for sale was the Albion mill engine, fig. 1; an inspection

steam acting on A B from without, A is made larger; acting on C D from between the disks, D is made larger; and under this slight difference of pressures, though each double valve is kept in its seat, it is lifted or depressed by its rod without strain or jar. Many other forms of valve are in use. In engines of which the cylinders oscillate upon trunnions projecting from their sides, now much in use, and known as oscillating engines; and also in rotatory or rotary engines, in which the steam drives round a revolving piston, the methods of supplying steam differ greatly from those above. In oscillating engines the steam and the exhaust passages traverse each a trunnion and support on either side; and they may be self-acting, the movement of the face of the trunnion over that of the support establishing and closing connection of each passage at the right point in the movement of the piston; or a steam chest and valves are employed, controlled by one or two eccentrics. This form of engine has many advantages; but almost insuperable defects in it are the heating and wear of the rubbing surfaces, which, with the spreading effect of the steam pressure, tend to produce and increase leakage of steam. The piston rod of a beam engine is attached by its cross head to one end of the working beam; and the rise and descent of this rod imparts to the ends of the beam a reciprocating movement, which, through the connecting rod from the further end, turns the crank. When the power acts by thrust and pull of an inflexible rod upon a crank, there occurs at the same two points in each revolution a momentary cessation of the rotative impulse. These points of no action are called the "dead points," and the rod and crank standing at either is technically said to be "on the centre." Obviously, the rotative effect upon the crank will, in each half revolution, increase from 0 at the dead point to a maximum when the rod stands at right angles to the crank, and then diminish in reaching the next from maximum to 0 again. The earliest, and in stationary engines the still almost universal method of continuing the movement steadily over the dead points, is by application of the fly-wheel upon the crank shaft. This is an iron wheel, of large diameter, and the very great weight of which is concentrated almost entirely in its massive rim. Brought to move at a given speed, it serves as a reservoir either of momentum or of inertia; hence tends to equalize the movement of the crank, as well as of the engine and machinery. The diameter of the circle described by the crank necessarily equals the length of stroke of the piston. Another method of equalizing the rotative pressure on the crank, is that of causing a pair of engines to act at once on the same shaft, their pistons impelling a pair of cranks placed at right angles to each other, so that when the action of one crank is 0 the other shall be at its point of greatest force. The effect of the fly-wheel upon the engine or machinery can

only be to prolong the transition from one speed to another; it cannot confine the working of the engine within the limits of variation that shall correspond to a desired average speed. The changes in the load or resistance worked against, as well as in the formation of steam in the boiler, are liable to be sudden and extreme. To confine the speed of the engine within certain limits is the office of the "governor," W, fig. 1. The number of forms now given to this is very great; but the principle of action in all is the same. The centrifugal tendency of heavy balls at the lower and free ends of two bars on an upright axis, is made to move a sliding collar and levers, and through these to control the throttle valve, which is fixed within the steam pipe like an ordinary pipe damper. On account of the friction of its axis and joints, the governor does not respond at once and completely to the speed impressed by the engine, and does not instantly compensate it. The later forms have usually in view to obviate this defect. Among them is the so-named centrifugal governor, in which two small balls swing on short bars from a single joint at the apex of the cone described in their revolution, and are caused to turn at a very high velocity; this arrangement not only works with less friction, but also by the more rapid revolution develops more speedily a centrifugal action competent to overcome that which remains. Evidently, the movement of the piston and its rod through the stroke should be rectilinear, or true in respect to a line which may be regarded as the axis of the cylinder, as otherwise the piston, stuffing box, and rod must be rapidly worn or wrenched out of form. In the engines called vertical, parallelism of movement is usually secured by the ascent and descent of the cross head of the piston rod within guiding grooves, in oscillating engines, the mere rocking of the cylinder continually adjusts it to the line of action on the crank; in other forms, generally, the piston rod is jointed, and parallelism of the rod below the joint, secured either by Watt's parallel motion or by guides. The former is much employed in English beam engines; it consists of an arrangement of levers and link-work, *p m*, fig. 1, attaching to fixed points and to the piston-rod joint in such way that, while the end of the beam necessarily moves through the arc of a circle, this joint and the rod below it shall move in almost an exact straight line. The real movement is, with most of these combinations, still in a double curve resembling a much flattened 8. It is because the long strokes and cranks generally preferred in American engines would exaggerate the departure from a right line, that in this country the use of guides to secure parallelism is almost universal. The "condenser" is a steam-tight and air-tight vessel or chamber, usually near the cylinder, into which, through the exhaust pipe, the spent steam from the cylinder is discharged during each movement of the piston, and in which it is condensed, either by circulation of

cold water over the surfaces of the reservoir containing the steam, or by injection of a shower or spray of cold water, or often in both ways at the same time. In condensing land engines, the injection water is supplied from the "cold well" which surrounds or encloses the condenser, and which is kept supplied by the "cold water pump," worked in beam engines by a rod from the beam. In marine engines the water enters directly from the sea by a tube or sort of inverted funnel pierced at top with small orifices, and rendered properly strong. The "blow-through" valves communicate from the cylinder to the condenser, and from the latter a "snifting valve" opens out to the atmosphere; all these are usually shut, but they are opened for blowing through steam in order to expel the air from the cylinder and condenser before the engine is set to work. The vacuum gauge on the condenser shows how much the pressure within it falls below the atmospheric pressure. Residual steam, air, and water are extracted from the condenser by the "air pump," also worked from the beam where that is present, and are discharged into the "hot well," from which by a tube these products are carried to the boiler and supply it with water, thus economizing much of the sensible heat resulting from condensation of the steam. "Surface condensers," now coming much into use, usually consist of a collection of tubes, of larger or smaller size, through or into which the spent steam is caused to circulate, and within which it is condensed by cold water surrounding the tubes, either as a current, or in form of a dense spray over their exterior. Of these the best now in use are probably Pirsson's and Sewell's. The cylinder and passages of the condensing engine being closed against the atmosphere, if a perfect vacuum could be instantaneously produced in advance of each movement of the piston, the total effect of pressure of the entering steam upon the piston would in all cases be utilized. Practically, this instantaneous and perfect vacuum is never attained; owing to time required for escape through the passages and imperfection of the condensation in the condenser itself, there is always a body of steam of low tension in advance of the piston, producing a residual pressure, and subtracting so much from the effective pressure of the entering steam on the other side of the piston. Still the resistance is less than that of the atmosphere; and a proportionate saving of steam power is realized in condensing engines. With steam, indeed, at one atmosphere, or not much above, the condenser is indispensable. As the steam is generated and applied at higher pressures, the gain by condensation becomes a smaller fraction of the total pressure applied, and the condenser is then, either for safety or economy, less serviceable. So, again, without condensation, the greater the pressure of the steam the less is the fraction or part lost by atmospheric resistance. And, simple as is the principle of the condenser,

its application along with the parts subservient to it imparts to the engine a good degree of its complexity, and greatly increases the weight of materials and the space required for it. Hence, to render the engine portable, the condenser and its appendages had to be discarded; the piston must then be driven both ways against the pressure of the atmosphere. Beside, the steam which had driven the piston must be expelled after each movement of it into the atmosphere; here, first, the heat contained by this steam is wasted, and secondly, since the orifice for escape cannot be made as large as the mouth of the cylinder, there is some delay and compression of the escaping steam, and an added resistance upon the piston due to this cause. In its working, then, the non-condensing engine is the less economical, and requires greater strength; but the saving in original cost, to say nothing of the need of portability, goes far to compensate for those defects; so that this kind of engine has come into general use, not only for locomotives, but very commonly also in the forms of stationary engine, and frequently for steam craft, especially those intended for river navigation. The pumps being dispensed with in the non-condensing engine, the beam may be so likewise; the piston rod being directed by a cross piece and guides, and a crank rod from this cross piece directly impelling a crank with or without a fly-wheel. III. *Classification and Varieties of Engines.* This branch of the subject has of necessity been in part anticipated in considering the essential parts of ordinary engines. Dividing steam engines with reference to the most essential distinction to be made between them, i. e., the physical principles upon which they are worked, we have the following two classes and principal varieties under each:

A. CONDENSING ENGINES—"LOW PRESSURE"

1. Acting by condensation only Atmospheric engines.
2. Acting by pressure and condensation Double-acting engines.
3. Acting by pressure, expansion, and condensation " "

B. NON-CONDENSING ENGINES—"HIGH PRESSURE"

1. Acting by pressure only Double-acting engines.
2. Acting by pressure and expansion, " "

Secondly, classifying with reference to the kind of movement the engine is to impart, we have: A, non-rotative engines, applying force directly by alternating movements, as in pumping, direct-acting steam hammers, &c.; B, rotative, giving movement to a revolving shaft, now rather the exceptions than the rule. Thirdly, in reference to the general purpose of their use, engines are: A, stationary, for propelling machinery, &c.; B, portable, for removal from place to place, but stationary while in use, as for sawing, pile-driving, &c.; C, marine, for propelling vessels; D, locomotive, for propelling vehicles on land. Fourthly, with reference to the mode of applying the action of the piston rod of ordinary cylinder engines, we have: A, beam engines; as 1, ordinary beam engines, the beam above; 2, "side lever" en-

gines, much in use in paddle steamers, the beam being placed below the level of the cylinder cover, and worked by a rod or rods descending to it from the cross head of the piston rod; B, direct-acting engines, in which the piston rod acts directly upon the crank; as 1, direct-acting horizontal engines, stationary; 2, direct-acting vertical engines, stationary or marine, in some forms known as "steeple" engines; 3, oscillating engines. Rotatory, disk, and certain other peculiar forms of engine are also direct-acting. Among the advantages of direct-acting over beam engines are the saving of space, of liability of damage to the cylinder from breaking down and fall of the beam, and of some useless load and friction; the parts transmitting the power in direct-acting being generally less than in beam engines, in the ratio of 2 : 5. The Corliss steam engine company, of Providence, construct a non-condensing horizontal engine, which is worked by Corliss's peculiar valve gear. These valves are segmental in form, and in their movement rotative-reciprocating. The steam passages, four in number, are reduced to the shortest practicable length, and each is controlled by a separate valve. The steam is employed expansively, the point of cutting off being controlled and regulated (without appreciable resistance) by the governor, so as to proportion the total pressure of the stroke continually to the desired rate of movement of the machinery; while a peculiarity of the action of the valves is the complete and almost instantaneous manner in which they open and close the passages, thus admitting the steam at or near the full boiler pressure, and preventing the effect known as "wire-drawing." Some of these engines have recently been furnished to orders from Scotland, the centre of steam engine manufacture. Non-condensing stationary engines are direct-acting, and have two principal plans of construction, the horizontal and the vertical. Of these the former are most common. The oblong form of base is now mainly superseded by a base in L form, of which the chief strength is in a vertical web; and the cylinder, crank, and fly-wheel are so attached to this that the strains arising in working the engine are best met, and the relative positions of the parts the most accurately preserved. Pumping engines are of various construction; among them the most noted and efficient are the so called Cornish engines. These engines economize the power they produce by dispensing with cranks, the fly-wheel, and many other parts to which ordinary forms of engine must impart movement; while for facility of admitting steam of very high pressure, for the great ratio of expansive working they allow, and the small amount of friction involved, they have for pumping taken precedence of all others. For Worthington's "duplex engine," for pumping, see PUMP. IV. *Behavior of Steam in the Engine, and how known.* The substitution of the elastic force of a vapor for the practically lim-

ited and unvarying pressure of the atmosphere, introduced a source of power susceptible of indefinite increase, and restricted only by considerations of safety and of practical advantage. The question, within what limits of steam pressure the maximum of advantage is to be attained, is however one involving so many variable quantities, dependent on the construction of the engine and the conditions under which it is worked, that no general determination of this problem has been obtained; and the desired information must be arrived at, if at all, by repeated experiments for each sort of engine and each set of conditions under which it may be worked. The tendency of such experiments has been to show a gain from the use of comparatively high pressures; so that, in condensing engines, the working pressure (in excess over one atmosphere) per square inch on the piston has been carried up from about 8 or 12 to an average of 25 or 30 lbs. Steam, as commonly employed, is drawn directly from the boiler, and generally in the boiler is saturated, or at maximum density. So existing, the slightest fall of the temperature, owing to abstraction of heat by the surfaces of the cylinder, by radiation, or otherwise, unavoidably determines the condensation of a portion of the steam. It is this instantaneous sensitiveness to cold and facility of condensation that most frequently prevent our attaining the working power of which theoretically the boiler pressure and the engine should be capable, and that oftenest defeat the special expedients resorted to for increasing their efficiency. When steam first enters the cylinder, the space it exists in is at once enlarged by that through which the piston moves; and if the steam space in the boiler and the heat for generating fresh supplies did not much exceed the capacity of the cylinder, the consequence would be a rapid reduction of density and pressure of the acting body of steam. With adequate boiler and furnace, however, the steam removed into the cylinder is continually replaced; and if the pressure be at first somewhat above that of the air, and the steam pipe kept open, the initial pressure of the entering steam may be regarded as, so far as this cause is concerned, maintained from beginning to end of each stroke of the piston. The disturbances in the actual pressure spring mainly from other sources. Even though it were uniform, the pressure on the piston is not equal to that in the boiler; a result due to length and winding of passages, to friction, with usually some condensation. Upon the piston the steam works in a twofold manner: first, by the tension it possesses as delivered freely and continuously into the cylinder; secondly, after the supply is cut off, by the expansion of the volume previously delivered, until in so expanding its pressure may fall to and be balanced by that of the atmosphere, or by the back pressure of the exhaust steam on the other side of the piston. Actuated in the

former manner through the entire stroke, the piston should advance under a uniform impulsion, its speed being constantly accelerated, and its momentum at last suddenly expended on some fixed parts of the machine, involving injury to the latter, and waste of power; when the latter method is, at the proper point in the stroke, made to supersede the former, the pressure gradually falling may be caused to approximate so nearly to, or to fall so slightly below, the back pressure, that the impulsion of the piston and its velocity shall gradually decline, and terminate naturally at or near the end of the stroke. So much cutting off and expansive working of steam is practically desirable in all engines; but this is not what is technically intended by "cutting off" and "expansion." In the mode of working specially so named, the steam being of comparatively high tension, the supply to the cylinder is cut off at an earlier period in the stroke; and expansion is availed of, not merely for avoiding waste, but as a positive means of deriving from a given volume of steam an augmented total of pressure, and so of performance. In strict language, the whole process is expansive acting; since so long as its pressure is in excess of that of the bodies that confine it, the steam must continue to push these bodies before it, in the tendency to arrive at equilibrium; and, with open ports, its expansive energy acts from the water in the boiler as its fixed point or fulcrum, as, after cutting off, it acts from the fixed end of the cylinder. For practical purposes, however, the distinction to be drawn at the point between full and expansive working is a real and important one. In actual working, again, the pressure of full stroke is seldom or never maintained quite uniform; owing to time consumed in shutting the ports, or to great speed of the piston, or to both, the density of the steam is reduced, and the pressure begins to decline before cutting off is complete; if this result is marked, "wire-drawing" of the steam is said to occur, the effect being as if the entering charge were gradually drawn or spun into steam of reduced density and pressure. In order that the steam may gain admission within the cylinder by the very moment at which the stroke should commence, the valve motion—the eccentric on the shaft, for example—must be so set in advance of the crank that the steam port shall be already uncovered or opened by a small fraction of the movement of the valve by the time the piston is prepared to return. This anticipative opening of the steam port is called the lead; and it may be greater or less, even to commencing the steam supply in front of the piston while nearing the end of its stroke, for the purpose of "cushioning" it, i. e., arresting its movement against the steam itself, as against a spring; the point of effecting this being simply determined by the adjustment of the valve gear, with the form and dimensions of the valve. Properly, one complete advance and

return of the piston constitutes a stroke; the respective half strokes, however, being termed forward stroke and return stroke. Let us trace the distribution of the steam during a stroke starting from either end of the cylinder. Suppose the piston, fig. 4, to have risen already to its highest position in the cylinder; now, in obedience to the position and throw of the eccentric, or to a connection with the governor, three events have just previously occurred: the returning valve has closed the exhaust from before or above the piston, locking up before it a residue of steam; it has at the same moment, or a little before, opened the exhaust beneath the piston, relieving it of the pressure that impelled it forward; and very shortly after these two events it has opened the steam communication above the piston by the amount of lead allowed, and commenced the steam supply. Under this last, having come to rest, the piston commences its forward stroke; the exhaust from before (beneath) it, having been previously opened, is maintained during nearly this whole movement; but first, and at the proper fraction of the movement, the steam supply behind (above) the piston is cut off. Shortly before completion of this forward stroke the exhaust in advance of it is closed, and that from behind is opened; and at a very small distance from the end the lead or admission of steam from beneath occurs, and in a moment more the arrested piston is ready for the return stroke. Thus, on the two sides of the piston there are at the same time proceeding two complete cycles of events, but in different parts of their course. In each cycle there are these four events, in their order: 1, admission of steam; 2, suppression or cutting off; 3, release, or exhaust; 4, arrest, or lock-up, prior to readmission of steam.—The pressure, and generally the behavior of the steam during a stroke in either end of the cylinder, is known by use of the indicator. This, in a usual form, fig. 6, is a

long, small cylinder, having within it a piston, which is fixed to the lower end of a spiral spring that attaches above and within to the top of the cylinder, and which, moving with little friction and carrying outside the cylinder case an index, is made by this to show and also to register the pressures of steam exerted upon it; thus it can indicate for any steam space the work the steam in it is capable of, or is performing. *O* is the cylinder; *s* a tube

with screw thread for fitting into an orifice in the cylinder cover, or in any passage, or the boiler, as may be desired; *e* the cock

opening or closing the tube. The index, *p*, fixed to the piston, rises and descends with it, one of its ends moving along a scale, *S*, showing the pressure in pounds per square inch on the piston; the other end having a joint by which a pencil is brought down in contact with a sheet of paper called the card, rolled about a vertical drum, *D*, and held upon it by clasps, as *f*. The spring is of such length that when the atmosphere entering above rests upon the piston, and steam of one atmosphere balances it from beneath, the piston shall rest in its natural or unstrained position; this point is the 0 of the scale. If the steam pressure exceed one atmosphere, it forces up the piston and index, compressing the spring; if it fall short, the piston and index are by the air carried proportionally down, elongating the spring. The drum can rotate about half way around a vertical axis, and when released is returned with a like uniform movement by a spring within. By the wheel, *W*, and cord, *r*, the connection needed to work the drum is made with some part of the machinery. To use the indicator: Connect it with the interior of the cylinder or other steam space; leave the cock open during a few strokes of the engine piston, to bring the indicator cylinder to a like temperature; and the pressures upon the indicator piston and, say, the engine piston may now be considered equal. Now, at beginning of a stroke, bring down the pencil to touch the card; the latter semi-rotating and returning, and the pencil rising and falling with the varying pressures through the stroke, there is traced on the card a curved figure, approaching more or less to an oblong, which is the "indicator diagram." Closing the cock at beginning of the next stroke, let the drum turn once or more while the pencil rests stationary; thus will be traced through or beneath the diagram, as the case may be, at the 0 level, the "atmospheric line." The lengths of ordinates drawn from this line to points of the curve above it will show the excess above one atmosphere of the steam pressure, and to

points. Of course, with high pressure engines the diagram will never run below the atmospheric line. In fig. 7 are shown two diagrams, the heavy-lined and dotted-lined figures, taken from a locomotive engine, under different conditions. A B, the atmospheric line, may also represent the length of stroke; the periods of the several events in the distribution of steam are here noted for comparison. The diagram is a picture of the operations in one end of the cylinder; and the indicator has been aptly said, like the stethoscope, to reveal what is transpiring beyond the reach of the eye. When accuracy is desired, diagrams are taken for both ends of a cylinder. A B, fig. 7, may stand for the length of stroke, and the space above this line represent the interior of the cylinder. In the heavy-lined diagram, taken with the slow average speed of piston, 40 feet per minute, the piston is seen here to start under the uniform pressure of 61 lbs. above the atmosphere; to preserve this nearly until cutting off of steam; the pressure during expansion then rapidly declining to about 28 lbs.; on release, still more rapidly; and before the end of stroke to come down completely to one atmosphere. During the return stroke, the back pressure remains thus low, until, upon lock-up, the pressure curve mounts rapidly; and at *a*, when the "lead" takes place, it sweeps still more rapidly up, regaining the full head by beginning of the next forward stroke. Here, with admission through about $\frac{1}{4}$ the forward stroke, and expansion through slightly more, inspection will show that about $\frac{1}{4}$ the whole work of the steam has been that secured by expansion. The dotted-lined diagram shows the behavior of the steam in the same cylinder, with speed of piston equal to 810 feet per minute, other conditions remaining the same. Here, the steam entering at initial pressure of 62 lbs., the quick recession of the piston before it allows the pressure curve to fall slightly; from wire-drawing near cutting off, it falls still more rapidly; after release, however, keeping higher than before, since the speed of the piston

FIG. 7.

points below the line the degree of exhaustion, for parts of the stroke corresponding to those

during admission and the early part of the expansion; and though during the latter part

does not allow time for exhaustion; and at no time in the return stroke quite falling to 0. If, when a slide valve is in middle position, the advancing edge on which-ever side already overlaps the port on that side, it must have closed that port previous to its reaching such position, i. e., to cut off earlier than in full working, and to work the steam expansively. The effect, the opposite of "lead," is called the "lap;" and the amount of the lap determines the ratio in which expansion shall occur. If the cylinder be colder than the admitted steam, a very sensible condensation occurs, both

of the expansion the remaining steam, becoming more tenuous and dry, re-absorbs part of this water due to condensation, yet there is an absolute and considerable loss, which increases as the steam is earlier cut off. In ordinary engines the waste due to this cause has been found often to exceed 12 per cent.; in exposed locomotive engines, to amount sometimes to nearly 40 per cent. And it is doubtless this source of loss, where the steam is not at all superheated and the heat of the cylinder not kept in, that often defeats attempts at expansive working of steam, and leads to a prejudice against the method, when the fault is in the unfitness of the conditions under which it is tried. No doubt one of the chief actual benefits of superheating steam through a few degrees, before admission to the cylinder, arises from its thus being supplied with a surplus of heat, by parting with a portion of which it keeps up the temperature of the cylinder, while another portion serves to prevent condensation or speedily to re-convert into steam the water due to its momentary occurrence. Back pressure in condensing engines is in part due to air liberated from the boiler water; but, on the principle that the pressure in communicating vessels is never less than that in the coldest part, it is chiefly that of the vapor in the condenser, its temperature being about 104° F., and its pressure 1.06 lbs. per square inch; in practice, the total back pressure is 1 to 3 lbs. or more. Back pressure is made less by enlarging the exhaust port. As to the measurement of the work of the engine: the indicator diagram represents, for each given point in the advance and return of the piston, the effective steam pressure or the back pressure exerted per square inch on the corresponding face of the piston. As the lines of the diagram are curved, its area must be found by a process of reduction or average. Divide the diagram into horizontal sections answering to the pressures, and into a convenient number of vertical sections, as shown in fig. 8; take the mean effective pressure in each of the vertical sections, add these together, divide by the number of such divisions, and the quotient is the effective mean pressure per unit of surface for the whole diagram; multiply this by the area of the piston in like units, and the product is the whole effective work upon one surface of the piston for one stroke. Proceed in the same way with a diagram for the other end of the cylinder; add the two results; take their mean; multiply by the number of single or half strokes of the engine per minute, and divide by 33,000 (see MECHANICS); the resulting quotient is the "indicator horse power" of the engine. In averaging the diagram, fig. 8, add the average pressures for the 10 divisions made in the stroke; their sum, 204.5, divided by 10, gives 20.45 lbs., the mean unbalanced pressure per square inch on the piston throughout the stroke. If there be two or more engines acting together,

the total indicator power must be found by adding the results given by the cylinders separately. This is the work upon the piston, under the total of resistances of every kind that must be overcome during, and to allow of, its movements; but to find what part of this work is expended upon the useful resistance overcome, or at any other connection between the piston and the useful resistance, so as to learn how much of the retardation of the pis-

ton is due to the machinery, or possibly to imperfections in it, it becomes necessary to interpose some form of dynamometer at the connection where the observation is to be made, so as to find by its indications how much of the total work upon the piston during a given time reaches and is expended at that connection. "Nominal horse power" is a conventional unit of size of cylinder, not of observed power of the engine. The rules of estimating it have differed with different localities, and they have usually allowed a larger unit of capacity for condensing engines. It is not much in use as a measure of value of engines in the United States; when it is so, the following is a usual form: $H. P. = \frac{\sqrt{\text{stroke in feet} \times \text{diameter}^3 \text{ in inches}}}{47}$

Actual horse power should be reckoned in actual units of pressure, to be known either by use of the indicator, or of a dynamometer showing the power delivered at the crank shaft. For the former, the rule may have the following expressions: Ind. H. P. =

$$\frac{\text{mean press.} \times \text{diam.}^3 \times .7854 \times \text{stroke} \times 2 \times \text{No. of turns}}{33,000}$$

$$= \frac{\text{pressure} \times \text{diam.}^3 \times \text{stroke} \times \text{No. of turns}}{21,000}$$

$$= \frac{\text{pressure} \times \text{area} \times \text{stroke} \times 2 \times \text{No. of turns}}{33,000}$$

V. *Work of Steam in the Engine.* The pressure of steam in the boiler, and within the steam chest or the cylinder, is commonly brought under direct observation by means of pressure gauges of various sorts (see PNEUMATICS), while the degree of vacuum in the condenser is indicated by the vacuum gauge. What is at different times called the "vacuum" of the condenser may be either the degree of actual vacuum produced, or the residual pressure. Thus, when the latter sustains 5 inches of mercury, it may be said in one sense that a vacuum equivalent

to 25 inches of mercury is obtained; in another and less correct sense, that the vacuum corresponds to 5 inches of mercury. In double-acting condensing engines, the piston is released from effect of the external atmosphere, and its work is performed and estimated independently of it. The indicated power of every steam engine is greater than the available power by the amount of energy expended in overcoming the resistance of the engine. The available power is the useful work the engine can perform in a given time, or rather the power it can impart in such time to the mechanism to be moved by it. The useful effect, or net available power, is a quantity involving three others, the velocity, the load, and the rate of evaporation in the boiler; and this net available power can be expressed and calculated in six different ways: 1, in foot-pounds per unit of time; 2, in horse power; 3, in weight raised per pound of fuel; 4, do. do. per cubic foot of water evaporated; 5, in number of pounds of fuel, or cubic feet of water to a horse power; 6, in number of horse power to a pound of fuel or a cubic foot of water. For the investigations by which formulas for these calculations are obtained, and for the modes of obtaining the requisite numerical solutions by them, the reader is referred to the more comprehensive works presenting the mathematical theory of the steam engine, especially to those of De Pambour, Tredgold, Bourne, and Rankine. The limit beyond which expansion cannot be advantageously carried seems to be that number of volumes found by dividing the initial pressure of the steam by the pressure in the condenser. This result of theory, however, proceeds on the supposition that the steam is maintained in the perfectly gaseous condition. Practical results seem to sustain Prof. Rankine's estimate, to the effect that the gain of efficiency in an ordinary engine, cutting off at one fifth, with superheating by heat from the flues steam of 34 lbs. pressure, is about 15 per cent.; if by heat otherwise wasted, as by carrying the steam pipe through the chimney, about 23 per cent. Though the principle of working steam expansively is very simple, and has long been accepted, the subject is not yet exempt from discussion or differences of opinion among engineers. Mr. King, in his "Practical Notes on Steam" (New York, 1861), estimates that by cutting off at half stroke the saving in fuel may be made nearly 20 per cent.; and for other ratios of expansion, within certain limits, in proportion. Engineers Isherwood, Stimers, and others, as the result of numerous and it would appear carefully conducted experiments with the engines of the steamer *Michigan*, at Erie, Penn., were led to conclude that the maximum gain by expansion is secured by cutting off at $\frac{1}{4}$ stroke; that to cut off much short of this affords no gain; that the loss by condensation in the cylinder, and by increased friction and back pressure, is generally underrated; and that the use of a variable cut-off

has usually not sufficient advantage over the ordinary throttle-valve, to compensate for its cost and the attention it may require. It may be considered doubtful whether these conclusions will be fully sustained; but they will at least have the good effect to call attention to the extreme to which expansive working has been carried, steam having been cut off in some cases at $\frac{1}{12}$, or even $\frac{1}{16}$ of the stroke. The ideal "cut-off" arrangement would be that which, first, should close the ports instantaneously at the proper moments, so that the steam should be admitted unreduced by wire-drawing, and enabled to act as it were with explosive force upon the piston; and secondly, which should be completely under control of the governor. The cut-offs now in use are very numerous, among them those of Sickels, Stevens, Allen and Wells, Corliss, Woodruff and Beach, and others. In respect to superheating of steam within limits from 10° to 40° above the temperature of saturation, it may be proper to add that the fears once entertained of its destroying lubrication, burning the surface of the cylinder or passages, &c., have proved quite groundless in practice; while at the same time, the notion that high superheating would greatly increase the effective work of the steam has also been discarded; so that superheating within moderate limits is now resorted to, mainly as a desirable condition for successful expansive working, or otherwise, merely as a means of preventing loss of the steam pressure. In practice, indeed, owing to want of heat conduction in fluids, with radiation of heat into the dome from the water surface, or from other causes, the steam in a high dome, and especially when the water beneath is for some time but slightly agitated, is in effect isolated from the water, and actually very often becomes superheated, unknown to the engineer. In some marine engines, also, steam is in practice surcharged with heat in the dome, by carrying flues through or around it. It is customary to estimate the efficiency of steam in a rough way by considering the effective mechanical force of a cubic foot of water vaporized as 60 horse power. If, then, this quantity of water be converted into steam in an hour, it will give a horse power per hour; and the boiler and engine that could generate and employ the steam of 10 cubic feet of water per hour, would give continually 10 horse power of work upon the piston. The high boiling point of water, but more especially the large degree of latent heat required to vaporize it, renders steam power expensive through necessity of a proportionately great consumption of fuel. Accordingly, various other vapors, as well as gases generated by explosion, have been tried as substitutes for steam. A comparison of the boiling points and latent heat of certain other liquids, with the relative volume and density (air being 1) of their vapors, will show theoretically their eligibility thus to serve as more economical substitutes:

1 cubic foot of	Boiling point.	Latent heat.	Relative volume.	Density.
Water.....	212°	965.9°	1,548	.694
Alcohol.....	173°	425.0°	550	1.614
Ether (sulphuric).....	97°	302.0°	443	2.586
Bi-sulphuret of carbon.....	116°	144.0° (?)	315	2.645
Oil of turpentine.....	314°	183.0°	198	5.018
Chloroform.....	143°	4.199

For accurate estimates, the specific heats must also be regarded; these by latest results are, for the vapors named in order, .305, .451, .481, .157, .506, and .156, that of an equal weight of water being 1. Thus far, however, engines driven by vapors other than steam, and also compound-vapor engines, have proved too expensive through waste of the material, and have not attained to a decided success. For the application of hot air as a motor, see *ATMOSPHERIC ENGINES. VI. The Production of Steam.* The capacity and principle of construction of the boiler or generator of steam must be determined generally with a view to the strength of the materials and the laws of combustion and of heat, and especially with reference to the specific purpose for which the engine is intended. In boilers for marine or locomotive purposes, rapid generation, security, lightness, and compactness should be attained, and if needs be at the cost of some waste of fuel; in those for stationary engines economy is the paramount object. Boilers before the time of Watt were usually in shape of an inverted frustum of a cone, with a hemispherical top and slightly concave bottom, and were set in an arch of brick-work, the fire being admitted to the bottom only, or also about the sides. To make a boiler stronger for its capacity and with greater heating surface, Watt introduced the long rectangular form, with semi-cylindrical top, the ends flat, the bottom and sides slightly concave, and set in a long arch; this was called the wagon boiler. The next transition was to the cylindrical boiler with hemispherical ends, as giving greater strength and heating surface. Subsequently a single straight flue, a single flue bent and returning, or two or more flues, were carried through the interior of the boiler; and the fire being made directly in these, or the heated air of the furnace being made to circulate through them while the water surrounded the flues, a much increased utilization of the heat of combustion was the result. From boilers with flues to those traversed by a large number of small tubes, in which the flame and heated air directly from the furnace shall circulate on its way to the chimney, thus exposing to the fire a maximum of water surface, the transition was a natural one; this form, known as the multitubular or tubular, is best illustrated in the locomotive boiler. The name tubular boiler is more correctly given to those boilers in which the tubes contain water, being surrounded by the flame. Flue and tubular boilers are those now most generally in use; they are either horizontal or upright. For a description of Messrs. Lee and Larned's annular boiler, see

FIRE ENGINE. The shell of the boiler, which may have a great variety of forms, is the general or outer wall, enclosing a space, part of which, as occupied by water, is the "water room," and the portion above this the "steam room." The furnace is the chamber which receives the fuel; when within the shell, this is called the fire box. The grate or fire grate is that part of the bottom of the furnace on which lies the fuel; it is constructed of "fire bars" or "grate bars," with spaces for admission of air. The part consisting of a plate, without such openings, is the "dead plate." The chimney affords draught and conveys away the final products of combustion; the flues or tubes for flame sometimes open into a chamber at its lower part, called the smoke box or uptake. The chimney, flues, or tubes may be controlled by dampers. The "tube plates" receive and are pierced by the ends of the tubes; they form either part of the shell, or one side of an internal fire box. The steam chest or dome, upon the upper side of the boiler, is the reservoir for the generated steam, which, as the various valves may allow, is supplied from it to the cylinder; or when its pressure exceeds the load upon the safety valve, directly escapes through this into the air. The height of water in the boiler is known by the water gauge, usually a strong glass tube standing outside the boiler; or by use of "try-cocks," three or more at different heights upon the boiler, and opened by hand. A pressure gauge shows the pressure within the boiler. A vacuum valve is a safety valve opening inward, to prevent collapse when the pressure within falls below that of the atmosphere. "Mud holes," at or near the bottom, are for the discharge, when needful, of collections of sediment; but it is very important, especially in marine boilers where sea water is used, to prevent such collections; and for this purpose sediment collectors, and various means for prevention of incrustation by previously precipitating the saline matters from the water, are employed. The apparatus for feeding the boiler with water, especially when the engine is at rest, may require to be driven by a separate and smaller engine; this is then called the "donkey engine." Feed-water heating, previously to admission of the supply to the boiler, may be accomplished in various ways; among them by carrying the water pipe through or about the flues or chimney. Brine pumps may be used for clearing the boiler of brine or sediment, or a large blow-off cock through the bottom of the boiler. Scum is removed by a scum cock or surface-blow at the surface of the water. The importance of keeping the water in the boiler always as near as possible to a certain height, so as to prevent liabilities on the one hand of priming, and on the other of burning or melting its sides or flues, or of explosion, will be very obvious; and a variety of devices, some of them already named, have been applied in order to aid and direct the engineer in this respect. Among the most recent,

and perhaps for safety the most valuable of such devices, are those known as "steam alarms," which are automatic, being caused to open a safety valve and blow a whistle or ring a bell when the water falls below a given level in the boiler. (See further, *BOILING POINT, COMBUSTION, EVAPORATION, and FUEL*.) The questions of the efficiency of steam boilers, the due proportioning of the fire grate, the flues, the heating surface, &c., to the capacity of the boiler and of the engine, and the duty of engines, are among those of great interest in the practical and commercial aspects of the subject, but for which space can only be allowed in the larger and specific treatises. It may be stated that in large land engines it is customary to allow for each horse power of pressure about 1 square foot of fire surface, 8 cubic feet of furnace room, 10 cubic feet of water, and 10 cubic feet of steam room. To vaporize the water, it is found in England, where coal is more cheaply obtained, and economy in its use not so much an object, that from 10 down to 8 or 7 lbs. of coal per cubic foot of water are consumed; in this country, in cases of good performance, the like effect is often obtained with about 6 lbs. of anthracite coal.

VII. Steam Boiler Explosions. These accidents are of different sorts; sometimes the metal is simply rent, steam or water or both escaping; sometimes the boiler or a flue is burst inward, a result known as "collapse;" but in explosions proper, the boiler is not only ruptured and often thrown from its place, but fragments of it are usually hurled with terrible force from the spot, accompanied with escape of steam and scalding water. Of certain peculiar theories proposed to account for explosions, one, to the effect that they are due to an electrical charge within the boiler, has no support whatever in facts, and is wholly visionary; a second, assigning as the cause the occurrence of an explosive mixture of gases within the boiler—hydrogen and oxygen being the only possible gases, and their presence in the needful quantities in any case being extremely questionable—is probably not less so. A recent projectile theory of explosions appears to add nothing to our knowledge of the accident; for though projection of the steam and water does occur, it is the effect of the steam pressure, and allowed by relative weakness of the boiler. M. Jobard (1861) has, however, shown that many explosions of stationary boilers are owing first of all to explosive combination of a sort of fire-damp of hydrogen and air, collecting in the chimney or flues during rest of the engine, and ignited on subsequently disturbing the fires, without previous opening of the dampers; the first effect is to throw the boiler out of place, and the flow of the water within it over its upper heated surfaces generates a pressure that next rends the boiler itself. Other causes or conditions which doubtless often lead really to explosions are the following: 1, in a boiler very highly heated, and without fresh feeding

for some time, the body of water may assume the spheroidal condition (see *EVAPORATION*), and a film of vapor lying between it and the metal, the latter can become unusually heated; on feeding cooler water or disturbing the fires, contact with the metal may be renewed, with sudden generation of steam of extremely high pressure; 2, by long boiling, without renewal, the water may become so far freed of air or other permanent gases that serve to form openings within its mass into which vaporization can begin, that its boiling point shall be raised, and when reached, a considerable body of the water, as has been observed in the experiments of Donny and others, shall burst suddenly into steam; 3, superheating may have taken place unsuspected within the dome, and when by fresh feed or rousing the fires the equilibrium within the boiler is disturbed, water being dashed up into the body of superheated steam, or otherwise, the sudden transfer of heat to the generation of saturated steam may instantly and very greatly increase the pressure. The last named cause could occur at any time during the running of an engine, if the steam became superheated and the boiling afterward more tumultuous; and any of these three causes can readily be supposed to occasion some of the explosions of stationary and steamboat boilers, known so often to occur upon first disturbing the water or fire after a period of rest of the engine. In all three of them, moreover, the production of an enormously great steam pressure may be almost instantaneous; so that the well known principle of blow or shock would come into play, the tenacity of the boiler giving way under the suddenness of the impulsion, before the limit of strength of the metal had been reached. Whatever be the occasion of explosions proper, however, their immediate cause is always the same—a momentary excess of the pressure of steam within the boiler over the strength of some of its parts. In the best arranged modern boilers, there are 2 or 3 safety valves, at least one of which is placed within the boiler, or otherwise beyond the control of the engineer. An advantage of tubular and small-flue boilers is the circulation of the water maintained in them, which retards or prevents formation of scale. Another, with water tubes, is the greatly increased strength to be had even with less thickness of material, owing to the relatively small diameter of the tubes; and further, since the same tube resists rupture from within up to pressures exceeding those that would cause flattening or collapse from without, it follows that, with like size and thickness of tubes, water-tube are stronger and safer than flue-tube boilers. The common impression respecting the greater danger of high pressure than of low pressure boilers, requires some qualification. In itself, and in one way, the high pressure is a source of increased risk; but the boilers generating such steam usually admit of being much smaller, and from this cir-

circumstances are relatively stronger; beside, they contain (locomotive boilers excepted) a less body of water and of steam to be projected about them in case of explosion. Low pressure boilers, on the other hand, have in them, when working, a large body of steam and also of water; when explosion occurs, this water being suddenly released from the confining pressure, much of the excess above 212° of heat in both the steam and water instantly goes to the generation of a greatly enlarged volume of steam; and this large body of scalding steam and water is projected through a more considerable space about the place of the boiler. Thus, the actual destructiveness and fatality consequent on explosion of the low pressure boiler are likely to be the greater, to say nothing of the fact that, from some of the peculiar conditions named above, even the projectile force given to the fragments and contents of the latter can be, in certain instances, quite as great as with the former. Obviously, most if not all the occasions of boiler explosions are avoidable, through, 1, avoiding the forcing of the fires; 2, keeping the valves in proper condition, and in no case over-weighting them; 3, applying the feed water regularly, constantly, and in sufficient quantity; 4, in case the plates are discovered, or where they are likely, to be over-heated, abstaining from the sudden introduction of feed water, drawing or extinguishing the fires, and blowing off the steam and water.—**STEAM CARRIAGE.** For information respecting the invention and early improvement of the locomotive engine, see **RAILROAD**, and incidentally **EVANS**, **STEPHENSON**, and **STEVENS**. The locomotive engine has so few points of resemblance to any other as to be essentially a new application of the same moving power. The use of steam at very high pressure and with rapid travel of piston, allows of a comparatively diminutive cylinder; while the high steam and great speed sought require a very large boiler and intense fire, to generate such steam with due rapidity. Intended, as its name imports, for locomotion, this engine must carry with it the water and fuel necessary to its action; and being subjected to violent strains and shocks, it should, along with the requisite conditions for furnishing the power, embody great strength and compactness of construction; to secure the latter, the engine and boiler are mounted together upon one carriage, through the wheels of which the tractive power is to be applied. Evans and others had placed the boiler and engine on one set of wheels; Trevithick and Vivian (1802-'3) separated the traction carriage, or locomotive proper, from those intended to receive the load; and they first discharged the exhaust steam from the cylinder into the chimney, to create draught. George Stephenson, about 1825, applied this principle much more successfully, perhaps re-inventing it, and to him it is usually assigned. Seguin in France, and Booth in England, in 1829, furnished the multitubular flue boiler;

the efficient adhesion of smooth driving wheels had before been discovered; and Stephenson's combination of all these essentials, with his direct connection of the piston rods, one on each side, with the propelling wheels, resulted in the first really successful locomotive, the Rocket, in the renowned "railway year," 1829. Timothy Hackworth contributed, before 1830, the six coupled wheels and the steam chamber over the boiler, placed the cylinders under the boiler, and made other improvements. The size and weight of the locomotive have been since that time much increased, and a construction highly perfected in detail and well adapted to the purposes desired has been attained. Modern English passenger locomotives are of two general types: 1, the "inside cylinder" locomotive, having the cylinders within the framing, under the boiler, with a main driving axle cranked at two points to receive the action of the piston rods; 2, "outside cylinder" locomotives, having the cylinders external to the framing, the axles straight, and the piston rods attaching each to a crank pin fixed between spokes of a driving wheel, the pin turning with the wheel about its axle, and serving as the engine crank. English freight or "goods" locomotives are also of two classes: 1, those with 6 wheels of like size, the 3 on either side having their crank pins coupled by horizontal bars called parallel rods, which secure the same crank action upon and movement of all the wheels; 2, those having the fore wheels smaller, the two back pairs only being of like size and coupled. The power of a locomotive, other things being equal, will depend on the amount of the steam pressure upon the piston; but a condition favoring is found also in the use of small driving wheels. As each revolution of the wheel to which the piston rod is attached must correspond to one stroke of the piston, it follows that speed of travel will depend on the speed of the piston, or number of strokes it can make per minute, but that it is also favored by use of large driving wheels. After many fluctuations, American practice has recently tended to the adoption of wheels of somewhat less diameter than those used a few years since. American locomotives are almost invariably outside-connected, i. e., have their cylinders outside the truck or engine frame, as well as nearly or quite on a level with the axles of the driving wheels. There are but two general types of construction, those for passenger and for freight trains. The former have 8 wheels, 4 in front set in a movable frame, the bogie or truck, turning on a central pivot to allow of running on curves in the road, and 4 larger ones behind, the drivers, or driving wheels, of equal size, and coupled with parallel rods. The freight locomotives are on 10 wheels, the leading 4 in a swivelling truck, and the 6 back wheels, 8 on a side, coupled as drivers. American locomotives are distinguished also by the cab or house at the back end to protect the

engineer and fireman, with glazed opening in front to afford a view ahead, and by the larger size and form of the chimney or smoke stack, a cylinder of wire net within an inverted cone, with wire net and baffle-plate above to deflect sparks into the intervening space—an arrangement specially adapted to the use of wood as fuel, and called the spark-arrester. Between the cab and the chimney of a locomotive appear, also above the boiler, the smaller dome in front surmounted with the steam whistle, the bell, and the dome proper. The "cow-catcher" or the snow plough may be attached forward, for the purpose of clearing the track; and in front of the chimney is also affixed a lamp with a parabolic reflector, for lighting the track in advance at night. The "tender," which conveys water and fuel, is a smaller carriage next the locomotive, and on 4, 6, or 8 wheels, arranged in two trucks, to facilitate turning. Its back and sides are occupied by the water tank, in horse-shoe form, holding from 800 to 1,000 gallons of water, while in the hollow of this is stowed the fuel, both being intended for some 15 to 30 or more miles run. The water tank communicates through pipes, connected by flexible hosing with two small lift-and-force pumps, worked from the piston rod, and the delivery of which can be regulated so as to feed continuously or at intervals. From the upper part of the dome the steam pipe opens out, descending and running forward within the upper part of the boiler, thence emerging within the chimney, where it divides into two branches, that run down and open each into the valve chest of one of the cylinders, each chest lying at the inner side of its cylinder. Sometimes the dome and commencement of the steam pipe are at the forward end of the boiler. In any case, while working, the chests are kept filled with steam which surrounds the valve—a single slide valve moved by one or two eccentrics and rods from the driving axle—and the steam is thus continually in readiness to flow into either port when uncovered, and to act upon that side of the piston corresponding. (See STEAM ENGINE, II.) The steam pipe may have in it a throttle-valve, under control of the engineer, through a lever handle and links. Thus the governor is rendered unnecessary, as it is also inapplicable. From length of passages, smallness of apertures, failure of the boiler to keep up the supply, or other causes, the pressure the steam can exert at and on the piston is always less than that it has within the boiler; and the necessity and mode of obtaining draught still further deduct from the effective pressure. The double-cased sides of the fire box, a space of $2\frac{1}{2}$ to 4 inches within which, directly about the fire, is filled with water, and the small flue tubes traversing the cylindrical portion of the boiler, conveying flame and hot air toward the chimney, and surrounded with water, can generate steam rapidly and of very high pressure. But to this

end, the fire must burn briskly, and the heated gases escape rapidly through the flue tubes, 100 to 200 or more in number, to the chimney. To secure the required draught through these, the exhaust pipe from each valve chest is carried directly into the chimney, and the two are united in a pipe called the blast pipe, which opens at a little height by a contracted mouth. The forcible and rapidly recurring puffs of the waste steam discharged from the cylinders out of this pipe into the chimney, carry with them the surrounding body of air, and create a partial vacuum, which can be supplied only by the consequent rush of fresh air through the grate, the fire, and the flues. Now, the contraction of the blast pipe needful to secure blast unavoidably keeps back somewhat the exhaust steam, and so results in a continued back pressure against the piston, while advancing either way under the last admitted steam charge; and when the speed of the locomotive, and so of the piston, becomes very great, this back pressure is correspondingly increased and rendered well nigh continuous. To accomplish successfully by use of the slide valve the required distribution of steam in the cylinders (see STEAM ENGINE, IV.) has been perhaps the most difficult problem in locomotive construction, and the one on which the greatest amount of ingenuity has been expended. In the case of a question so highly mathematical and technical as this, nothing beyond an intimation of the objects sought and of the means employed to attain them can be presented; the reader will find the subject fully discussed in Mr. D. K. Clark's "Railway Machinery" (Glasgow and London, 1855). First, the valve should be so moved as to admit and discharge steam when the piston is at or near the beginning or end of the half strokes; secondly, the valve gear should render a variable expansion, or ratio of cutting off, practicable; and thirdly, the valve gear must be capable of reversing at will the action on the piston, so as to reverse the movement of the engine and carriage. Remembering that the diameter of the crank circle equals the length of stroke of the piston; that when the crank pin and piston rod are in the horizontal diameter of the crank circle the piston is at beginning or end of stroke; that when the crank pin is in the vertical positions the piston is about midway in either half stroke; and that in a general way admission and exhaust should begin to occur about the times when the piston begins or ends a half stroke; it will be seen that, to accomplish the first purpose, the valve should begin to open either port to steam and the other to exhaust about the time when the crank pin and rod are in the horizontal positions. Now, remembering further that an eccentric turning on an axle is essentially itself a crank, the distance of the centre of its form from the centre of motion being the length of crank, and double this distance being the diameter of this crank

circle, and also the length of the throw the revolution of the eccentric will impart to its rod; that the valve moving either way from its middle position will be just beginning to uncover the ports; and that it will be in such position when the centre of form of the eccentric is in the vertical positions in respect to the axle, it will be seen that, with a single eccentric and rod, the first object is attained by setting the eccentric so that its radius shall be "quartering" or at right angles with the line of the crank pin from the same axle. Thus, the general result secured is, that whenever the crank is in horizontal position, and the piston at beginning or end of stroke has its slowest movement, the eccentric is vertical, and the valve in middle of its throw has the most rapid movement, as required for duly opening the ports; and *vice versa*. An engine moving at high speed, say 33 miles an hour, or 1,093 yards a minute, the driving wheels 5 ft. 8 in. in diameter, or about 16 ft. 6 in. in circumference, the number of strokes of each piston must be about 200, and of separate or half strokes 400 per minute; if the length of each be 18 inches, this gives the piston an average velocity of 192 yards per minute, or 10 feet per second, i. e., more than three times the usual speed in stationary engines; thus it will appear how important is the proper timing of the steam changes within the cylinder, and how nice must be the adjustments required for economical and perfect working. The third of the

objects above named is, with any method of valve motion, accomplished by means of a reversing handle at the command of the engineer, which by lever and links is made to detach the eccentric rod or reverse its action on the valve, and consequently the direction of movement of the crank and of the wheels. This is employed as an auxiliary means of arresting the movement of the engine and train at high speed, or for the purpose of backing the engine. The second of the three objects named above is that which has presented the chief difficulty. The outer edges of a slide valve determine the times of admission and of suppression; the inner, the times of release and compression. Outside "lap" of valve conspires with

FIG. 9.

"lead" to secure early admission of steam and early and efficient release; inside lap defers release and prolongs expansion; while inside clearance shortens both expansion and compression. Thus, these three elements, the lap, lead,

FIG. 10.

and throw of the valve, control the distribution of the steam; and any change in either affects the distribution in a definable way. Up to about 1842, a variety of complicated expansion gear for locomotive slide valves had been devised, for varying the travel or length of throw of the valve during stroke, and hence the expansion; and though the link motion then introduced has since come into almost universal use, yet such devices, with single or with complex or cut-off slides, have continued since to be presented. Of the link motion, the simplest and most satisfactory solution of the problem, the construction in one form of shifting link is represented in fig. 9, while the mode of action will be better understood by aid of the diagram, fig. 10. In the figures, *v r* is the valve

rod, which by a stud or pin within the link can be made to stand at different heights within it; *l l* is the link; *e* is the fore and *e'* the back eccentric, jointly giving movement to the link; their centre of motion is at *c*, their centres of form, *a, c*; *o c, o c* are their radii; *f* is the fore and *b* the back eccentric rod, the relative positions appearing reversed in the two figures; *C* is the crank; *c a* its radius; *a r a* a half revolution of the crank; *v* is the slide valve; *p p* are the steam ports and *E* the exhaust, to the cylinder; *n* represents the reversing link, *h* the reversing lever; but the mode of reversing is better shown in fig. 9, in which *k* is the supporting link, *B* a bent lever, with counterpoise *W*; *R R* a rod from the lever *B* to the reversing lever or handle, *L*, at the hand of the en-

gineer. Fig. 10 represents the shifting link motion, in mid-gear, at beginning of the back stroke. The origin of the link motion, in an impracticable form however, has been traced to a Mr. Williams of Newcastle; it was worked out by Mr. Howe, and applied to Stephenson's locomotives, and is generally accredited to Robert Stephenson. The motion attained is equivalent to that of a variable eccentric. If two eccentrics be differently set on the same axle, each will be the equivalent of a crank, giving to its rod a definite throw or stroke equal to twice the eccentric radius; and the movement of either eccentric in any part of its revolution can be resolved into two component motions, tangential and radial. Now, in the link motion, two eccentrics have their centres of form in nearly opposite directions from the same axle on which they turn, and their rods, instead of attaching to the valve rod, take hold of the upper and lower ends of a curved, slotted link; the valve rod by a stud or a pin within the slot can be so shifted as to be worked from either end of the link, or from intermediate points in its length. The motion of the link is compounded of the distinct motions of the eccentrics, which, as respectively intended to give forward and backward strokes, are called the fore and back eccentrics. The motion of each eccentric prevails in that half of the link to which it is coupled, the motion at middle point being equally composed of the two; so that the horizontal movement, distance of travel, or throw which the link will impart to the valve rod, is a minimum when the rod is actuated from the middle of the link, and increases toward the extremities, but with a movement in the two in opposite directions. The link is shifted, or the block and valve rod pin within it, by means of the reversing lever at the hand of the engineer; and thus various lengths and speeds of throw of the same valve are secured with various periods of admission, expansion, and release of steam. Link motions are thus of two classes: 1, the stationary link with shifting block; 2, the shifting link with stationary block. With these the results attained slightly differ; and beside, the principle, application, and effects of the link motion are capable of very great variation. Usual dimensions are, to give to the valve a lap of 1 inch, lead $\frac{1}{4}$ inch; the throw of each eccentric, $4\frac{1}{2}$ inches; length of eccentric rod, 54 inches; length of the link between attachments of these rods, 12 inches; with dimensions of the subsidiary links and levers in the proportions required. Then, certain main positions of the link and valve rod, as secured by the reversing lever, are as follows:

Positions.	Eccentric used.	Length of travel of valve, inches.
Full gear forward.....	Fore.	4 $\frac{1}{2}$
Half gear forward.....	Fore.	3 $\frac{1}{2}$
Mid-gear.....	Both.	2 $\frac{1}{2}$
Full gear backward.....	Back.	4 $\frac{1}{2}$

With the stationary link a constant lead, through

fore and back gear, and for forward and back strokes, may be had. This the shifting link fails to give; the lead here varies with the expansion, being least in full gear, and a maximum in mid-gear; but it may be made the same for the forward and back strokes. An admission through $.75 = \frac{3}{4}$ stroke, is attended with a mean expansion of 16 per cent., with release at $.91$ of stroke; while $.50$ admission gives about $.80$ expansion, exhausting at $.80 = \frac{4}{5}$ stroke. The least attainable percentage of admission, with the different forms of link, varies from $.11$ to $.17$ of stroke.—If, in an engine working under a given set of conditions, including a given action of valve gear, the boiler cease to supply the number of cylinderfuls of steam required at the velocity, the pressure on the piston and the speed proportionally fall; or if the ascent of grade increase, the resistance and work being greater, the piston cannot advance so rapidly, and the speed again falls, unless the power of the boiler suffice to raise the tension of the steam. On the other hand, if while the grade remains the same the steam pressure rises, or the pressure the same the grade diminishes, the engine runs faster, and until the increasing resistance mounts to an equilibrium with the power. Thus the true measure and limit of power of the locomotive engine are in the evaporative power of the boiler. But the calculations of power and speed belong to the subject and works of railway practice. The following table presents some examples of the tractive resistance per ton gross of engine, tender, and train on a level:

Speed, in miles per hour.	Resistance, in lbs. per ton.	
	Under superior conditions.	Under ordinary conditions.
10	8.6	13.0
20	10.3	15.5
30	12.2	20.0
40	17.3	24.0
50	22.6	34.0
60	29.0	45.5
70	36.6	55.0

—Since about the year 1830, and until within a few years past, the rapid improvement and introduction of railway locomotion had quite absorbed the attention of inventors, and the problem of steam carriage on common roads was comparatively neglected. The difficulties in the way of such propulsion of vehicles, moreover, remain considerable. In the great exhibition of 1851 there was but one locomotive for common roads exhibited; but since that time, in England, no fewer than 9 varieties of such engines have attracted attention, some of which have been employed for agricultural or for carrying purposes, and perhaps the most successful of which are the traction engines of Bray and Boydell. Among those interested in the subject in the United States, Mr. J. K. Fisher has thus far been the most successful. He built in New York in 1852 a small experimental steam carriage, with easy springs. This, on the Broadway pavement, in night trials, outran horses; but it had not steam

enough for common roads. He has now (1862) nearly completed a large carriage; and four self-propelling fire engines of Messrs. Lee and Larned's patent (see FIRE ENGINES) have been built, so far as their locomotive apparatus is concerned, on his plan. These all have springs of great flexibility, and yet run as steadily as ordinary carriages. This result is attained by using radius rods to hold the driving axle at a constant distance from the engine shaft, which revolves in fixed bearings in the main frame, allowing the axle to swing or to rise and fall, parallel rods being introduced to transmit the power. The parallel and radius rods terminate in ball and socket joints; and the lateral swing is limited by a transverse radius rod held by a spring. By these several methods, not only are the necessary lateral movement and flexure due to roughness of roads allowed, but also the rolling or oscillation of the carriage, without twist of the frame, or interfering with the accurate transmission of the power to the driving wheels. Of the steam fire engines, the cylinders are of $7\frac{1}{2}$ inches diameter and 14 inches stroke; the valves operated by a stationary link with reversing lever, and securing expansion in any desired degree. The power is derived from Lee and Larned's annular steam boiler. The speed of steam carriages on good common roads has been made to reach 80 miles per hour for short distances, and for journeys of three miles 20 miles per hour.—STEAM NAVIGATION. Paddle wheels, propelled by windmills turned by men, or by animal power, were to some extent in use in the war galleys of the ancient Egyptians and Romans; it is uncertain whether they afforded any essential advantage over the use of oars. Even if Blasco de Garay, mentioned in treating of the steam engine, accomplished what has been claimed, the entire abandonment of his project shows that it must have been unsatisfactory; so that he can in no way be regarded as the originator of steam navigation. The attempts made in England and France, prior to 1730, led to no result. Jonathan Hulls in 1736 described a method of propulsion by a stern wheel acted upon by an atmospheric engine; but he is not known to have put his plan in practice. In France, from 1774 to 1796, the count d'Auxiron, the brothers Pénier, the marquis de Jouffroy, and M. des Blancs severally constructed and tried boats to be propelled by steam, none of which were successful. In 1786 John Fitch, of Pennsylvania, propelled by a very small engine, cylinder one inch in diameter, a skiff at fair speed; and in the same year, by a 12-inch cylinder, a boat on the Delaware, the speed however being in this case very slow. In 1787 Rumsey, of Virginia, attained a speed of at least 8 miles an hour on the Potomac, by reaction of water taken in at the bow of his boat by a steam engine and forced out at the stern; he tried this plan in England in 1798, making 4 miles an hour. Fitch's boat of larger size, placed on the Delaware in 1790, and making regular trips through-

the season, at an average of $7\frac{1}{2}$ miles an hour, did not still lead to the general introduction of steam propulsion; though this clear-sighted pioneer predicted the navigation by such means not only of the western waters of America, but also of the Atlantic ocean. Thus, the actual moving of boats by steam certainly occurred in this country, and perhaps in France, before the trials of Miller and others in Scotland, on which latter, however, the English endeavor to found their claim to priority. Patrick Miller and William Symington, in 1788, propelled on Dalswinton loch twin or double pleasure boats, by means of a paddle wheel placed between them, and by an engine with a 4-inch cylinder, attaining 5 miles an hour. With a larger engine, in 1789, they navigated the Forth and Clyde canal, at a rate of 6 to 7 miles an hour; but owing to insufficiency in the machinery, they were compelled to abandon further attempts. In 1798 John Fitch moved a small boat on the Collect pond, in the city of New York, by a small engine and a worm or propeller screw projecting from the stern of the boat; this being, probably, the first employment of the screw for propulsion. In the same year a work was published in Florence, claiming that an Italian, Serapino Serrati, had successfully propelled a boat by steam on the Arno; if this be true, still no further practical result followed upon it in that quarter. Meanwhile, Robert Fulton was in England and in France, and, if not previously interested in steam propulsion, became so upon inspection of Dr. Cartwright's steam barge, and Earl Stanhope's boat with duck-foot paddles under the quarters, neither of which however proved successful. In 1798 the legislature of New York granted to Chancellor R. R. Livingston of that state, who had been experimenting with steam for boats, the right to navigate the waters of the state by steam for 20 years; and though he failed to satisfy the condition of the grant by propelling a boat 4 miles per hour within the year, the grant was in 1803 renewed, and the time of fulfilment extended to 1805, and afterward to 1807. In 1801 Mr. Symington completed for Lord Dundas a steamboat, the Charlotte Dundas, its engine having a horizontal cylinder of 22 inches diameter and 4 feet stroke; this made, with boats to 140 tons burden in tow, on the Forth and Clyde canal, $8\frac{1}{2}$ miles per hour; but a prejudice excited by its washing the banks of the canal compelled its abandonment. About 1799, Mr. Livingston meeting with Fulton in Paris, they became together interested in projects for steam propulsion, and, notwithstanding the jealousy of Des Blancs, made at least two experiments on the Seine previous to 1804, neither of which succeeded. The breaking in the middle and sinking of their boat in the first instance by the weight of the engine, is believed to have led to Fulton's subsequent introduction of the strong and light framing intended to uphold the weight of large engines,

which is one of the characteristic excellences of American steamboats. It was in 1804 that Oliver Evans, at Philadelphia, propelled his steam dredging machine, the *Oructor Amphibolia*, upon wheels on land, and subsequently by a paddle wheel upon the water. In the same year John Stevens, of Hoboken, N. J., propelled in the waters about New York a small boat by means of an engine, the steam for which was furnished by a very small tubular boiler, the power being applied by means of a form of screw also invented by him, and substantially that most approved at the present day. Fulton, meanwhile, had again visited England and Scotland, inspecting in the latter country one of Symington's later boats, and receiving from him information respecting its construction and working. Returning to New York in 1806, he commenced at once building, in conjunction with Mr. Livingston, a steamboat for use upon the Hudson. This boat, the *Clermont*, was of 160 tons burden, 180 ft. long, 18 ft. wide, and 7 ft. deep. She was provided with an engine from the establishment of Boulton and Watt, with a single cylinder 2 ft. in diameter and of 4 ft. stroke; boiler 20 ft. long, 7 ft. deep, and 8 ft. broad. The diameter of the paddle wheels was 15 ft., the boards 4 ft. long, and dipping 2 ft. in the water. On the morning of Aug. 7, 1807, Fulton with a few friends and mechanics, and 6 passengers, and leaving on the shore an incredulous and jeering crowd, started for Albany. The distance, 150 miles, he made at a speed of nearly, and on his return of full, 5 miles an hour. As the speed was still less than had been anticipated, the boat was lengthened to 140 ft. keel, and, being otherwise altered, was early in the year 1808 placed for regular trips on the Hudson between the cities already named. By tracing thus far the history of steam propulsion on water, we find that Fulton cannot be said to have been the originator of steam navigation, nor indeed the inventor of mechanism for such navigation; but the credit belonging to Fulton is that of having been the first successfully to cross the chasm from mere attempts to positive achievement—the man through whose energy and skill was first secured that combination of means which rendered navigation by steam at once practicable and profitable. Very properly, therefore, do the committee of the first London exhibition, 1851, say: "Many persons, in various countries, claim the honor of having first invented small boats propelled by steam; but it is to the undaunted perseverance and exertions of the American Fulton that is due the everlasting honor of having produced this revolution, both in naval architecture and navigation." Within a brief period after the first trip of the *Clermont*, Mr. Stevens launched his boat, the *Phoenix*; but as Fulton's success had secured the right to navigation of the waters of New York, R. L. Stevens, son of the former, boldly took this boat round to Philadelphia by sea, this being indisputably the first instance of

ocean steam navigation. (See STEVENS.) He also greatly improved the speed of his boats, attaining in 1814 to 18½ miles an hour. In 1812 the first regular passenger steamer in Britain, the *Comet*, built for Henry Bell, appeared on the waters of the Clyde. This vessel was of 40 ft. keel, 10½ ft. beam, 25 tons burden, and 8 horse power; her speed was 5 miles an hour. In 1814 Boulton and Watt first applied two condensing engines, connected with the shaft by cranks placed on it at right angles, in a steamer to run upon the Clyde. This plan has since become for boats of larger size a very general one. In 1818 the *Savannah*, a New York built ship, with side wheels, and propelled by steam and sails, crossed the Atlantic to St. Petersburg *via* Liverpool, reaching the latter place direct from New York in 26 days, and returning in safety. Although this was the first crossing of the Atlantic by steam, yet as the ship had but small engines, and was unsuited to the risks of such a voyage, the event scarcely demonstrated the practicability of ocean steam navigation. The first regular passages were made by the *Sirius* and *Great Western* in 1838, the former making the trip from London to New York in 17 days, and the latter from Bristol to New York in 15 days. In 1811 Fulton and Livingston established a ship yard at Pittsburg, and built an experimental boat, the *Orleans*, the first ever placed on our western waters. This boat had stern wheel and masts; her first trip from Pittsburg to New Orleans was made in the winter of 1812. This seems to have been the first successful application of the stern wheel, now in very general use on the western rivers, especially for boats of light draught. (See also SHIP.) Of the best class of American river steamers, a good example is the *New World*, built in 1847, of 1,400 tons, and placed on the Hudson between New York and Albany. Her engines were built by the firm of T. F. Secor and co., condensing, of 76 inches diameter and 15 ft. stroke, provided with double balance valves and Stevens's cut-off, worked by the usual eccentrics, lifter rods, and rock shafts with their levers; the two boilers being circular, and with single return flues. Of this boat the length is 87½ ft.; breadth, 86 ft., over guards 69 ft.; depth of hold, 10 ft. 6 in.; the average speed of run, landings not included, is 18½ miles per hour. The steamers *City of Boston* and *City of New York*, running on Long Island sound, embody a more recent style, in some respects, of construction and of propelling machinery; their engines are from the *Novelty* iron works, New York, hull by Sneed and co. The *Daniel Drew*, running upon the Hudson, has recently made, on a trial trip, a speed of 22 miles per hour. The successful introduction of the screw was through the experiments of Capt. Ericsson and F. P. Smith, on the *Thames*, in 1837. The speed attained, with a large ship in tow, and against tide, was 4½ knots an hour. The next screw vessel, the *Robert Stockton*,

built in 1839 for an American gentleman, was also successful; while the success of the *Archimedes*, in 1840, of 232 tons and 80 horse power, was so great as to attract the attention of the English admiralty; and from this time the screw advanced rapidly into favor, employed either as sole or as auxiliary means of propulsion for men-of-war or fast-sailing merchant vessels.—Many peculiarities in the construction of marine engines, their accessories, working, and forms of boilers, have already been mentioned in treating of the steam engine. To combine the three things requisite in a steam vessel, the ship, the engines and boilers, and the wheels or other propeller, each of which is in itself a complex study, is one of the most difficult problems of modern engineering, demanding in the highest degree theoretical attainments and practical skill. The marine steam engine is necessarily made as light, compact, and at the same time as economical of fuel as possible. One of its oldest varieties, the side lever form, is still in use in some of the largest paddle steamers, among them those of the Cunard line. Although it has many advantages, yet, in view of the value of space and weight in merchant and passenger steamers, it is probable that the lighter and more compact direct-acting forms of engine, though more expensive in working, are in the total more economical. The screw propeller, or screw, which is the means of propulsion in those vessels named from this circumstance screw steamers or propellers, consists in its simplest form of a very strong metallic plate, standing edgewise on a cylinder or shaft, and winding round it like the blade of an auger, or of two or more blades or vanes, forming parts of such spirals. The shaft is made very strong, continued within the hold of the ship, and intended to revolve. The screw or blades are upon that part of it projecting from the stern of the ship, and space for the turning of the blades is allowed by a vertical oblong recess in the keel and stern, just before the rudder. The position of the shaft is such that the screw shall usually be wholly submerged; and upon the portion of the shaft within the hold one or more engines are made to act, either by cranks formed on the shaft, or by means of geared wheels. The use of such wheels admits of a slow speed of piston with a high speed of the screw; while on the other hand these wheels are necessarily cumbrous, their wooden teeth are liable to be "stripped" or broken off by a sudden stroke of the sea upon the screw, and they are unavoidably attended with a loud and disagreeable rumbling noise. Vessels of considerable draught admit of a diameter and pitch of screw sufficient for propulsion, without undue speed of the piston and without gearing. In the best marine engines the deduction for friction, the working of valves, pumps, &c., from the indicated or gross horse power, in order to find the effective or available propulsive power, may be taken as usually about 25 per cent. To increase the linear

advance of a screw against the water, which corresponds with a given rate of turn called the "pitch," the number of revolutions of the screw must be increased; and as the pitch best for effect is limited by the diameter of the screw, and this by the draught, and as for each revolution of the screw two journeys of the piston are allowed, the time, and hence the stroke, is necessarily short; the disadvantages are, the more frequent recurrence of the dead points, a proportionately greater loss of steam in filling the passages to the cylinder, and a narrower limit to the employment of expansive working. Still in most marine engines, whether for paddles or screws, steam is worked expansively, though seldom to the same extent as in land engines; the best results being secured when the cylinder is surrounded both with jacket and clothing, or the steam sufficiently superheated. In respect to the necessity of preventing accumulation of saline matters in the boilers of sea-going vessels, with consequent raising of the boiling point and tendency to scale within the boilers, it is now the usual practice to blow off the requisite quantity of brine continuously, and from the surface as well as the bottom of the boiler, in due proportion to the quantity of feed water admitted, so as to keep the water at that degree of saturation found by experience to be attended with little or no deposit. The density of the brine is known either by the hydrometer, or by instruments for the purpose termed salinometers. One of the most dangerous and troublesome tendencies of a boiler is that known as priming, as, beside the great loss of heat and of steam pressure occasioned by it, it may also cause the breaking down of the engine by the shock of the piston on the incompressible fluid in the cylinder. Remedies resorted to are, the increase of size of the steam chest, increased height of the steam pipe orifice above the surface of the water, and sometimes the adding of tallow to the water in the boiler. By the throttle-valve of marine engines, the flow of steam to the engines is usually regulated or shut off by hand. The ordinary vertical form of governor is of course wholly inapplicable, through the pitching and rolling to which the ship is liable. But in a heavy sea, one wheel or the screw being sometimes lifted quite out of the water, the engine begins to "race," i. e., to fly off at very high velocity, the liability to this result being greater with screw than with paddle steamers; and in such case an automatic and prompt-acting substitute for the hand becomes very desirable. The desideratum in these cases has recently been supplied by 3 or 4 different contrivances. The earliest of these were Silver's "momentum-wheel governor," and his "four-ball" or "balanced governor;" these instruments act equally well in any position. The same result is secured in a more recent invention, Porter's "marine governor," with suspended and balanced balls, acting by compression, according to speed, of a spiral spring. In

all these forms it is true that the remedy must be applied after the evil has begun to develop itself. Jensen, of Copenhagen, has accordingly attempted to produce a prompt and perfect marine governor, by admitting the water of the sea to rise in two small cylinders directly through the bottom of the vessel, and as near as may be to the screw or wheels; pistons moving on and with the water in these cylinders, are made by levers to control the steam valves; and thus the irregular immersion of the vessel itself is caused to regulate the supply of steam to the engines.—Paddle wheels are generally of two kinds, those with common or fixed, and those with feathering floats. Wheels with fixed floats, when a vessel is anchored or is yet moving slowly, act at great disadvantage; since those entering the water strike it obliquely, and waste much of the power in a tendency to lift the bow of the vessel, instead of propelling it, and those leaving the water lift much dead weight in the form of back water. But when the vessel has acquired fair or rapid speed, its very motion largely overcomes these difficulties, and the dip of each float into the water, and its withdrawal out of it, virtually occur nearly edgewise, the effect being similar to the "feathering" of an oar by the rower. But with a paddle wheel badly proportioned, immersed too deeply in the water, or attached to a slow boat, the unfavorable action above referred to is largely experienced. By making the floats movable about horizontal axes through the middle, and controlling their position by a second wheel, set eccentrically to the paddle wheel, as well as in other ways, they are made to feather on entering and leaving the water. By such arrangement the speed has been increased, and the vibration due to the movement of the wheels greatly reduced. The excess of the velocity of the wheel above that of the vessel, called the slip, is in favorable circumstances about $\frac{1}{2}$ the speed of the latter; feathering wheels have less slip. As, in the screw, one, two, or three threads are readily placed within the distance of a single coil, we have thus single-threaded screws, double-threaded, and so on. The distance to which the screw would enter a solid during a single revolution, is of course the distance or length of one complete turn; and this is the measure already named the pitch of the screw. But since, worked in water, the medium gives way in part before it, the screw does not advance the full amount of its pitch, and this deficiency is called the slip of the screw. Supposing the screw cut into portions by planes at right angles to its axis, these would be the vanes or blades; and according as the screw was two-threaded or three-threaded, two or three of these would stand opposite each other. This form, in which each blade is but a small portion of the complete pitch, is that now commonly in use. What is called negative slip in propeller screws, is that result in which, owing to the drawing by the ship of a wake or

current after it, the screw acting in this current causes the vessel to advance faster than the blades of the screw at the same moment are entering the water or would enter a solid surrounding them. Owing to the current, however, the real slip is not apparent. In reference to the comparative value for propulsion of paddle wheels and screws, it may be said that when both are in their best trim, and well proportioned to the vessels and the engines, they are about equally efficient. The screw, however, in ordinary weather, is apt to have a more uniform immersion and action; while a great disadvantage of its use is the increased speed which must be given to the engines.

STEARIC ACID (Gr. *stear*, tallow), a fatty acid obtained from mutton suet, and other fats that contain stearine, by the process described in *CANDLE*, vol. iv. p. 855; symbol, $\text{HO}, \text{C}_{18}, \text{H}_{35}, \text{O}_2$. When recrystallized from ether, until the fusing point becomes constant at 159° , and slowly cooled, the acid forms beautiful, colorless, transparent, rhombic plates; these melt into a colorless oil, tasteless and without odor, and when quickly cooled the substance concretes in a white crystalline mass, which is insoluble in water, but readily forms with hot alcohol a solution having acid reaction. It is the material of the so called stearine candles. Stearic acid exists in fats in combination with glycerine, forming stearine, from which it is separated by saponification. (See *GLYCERINE*.) It combines with numerous bases, and forms with them both acid and neutral salts, called stearates. Stearate of soda is the basis of ordinary hard soap; stearate of lead is one of the constituents of the common lead plaster.

STEARNS, a central co. of Minnesota, bounded E. by the Mississippi, and drained by Sauk river and lake; area, 1,879 sq. m.; pop. in 1860, 4,505. A portion of the county is prairie, but the W. part is mountainous. There are numerous lakes and streams. Capital, St. Cloud.

STEATITE, or **SOAPSTONE**, a compact variety of the mineral species talc, consisting of silica 62.14, magnesia 32.92, and water 4.94 per cent., being a hydrous silicate of magnesia. It occurs in massive beds among the metamorphic rocks, often associated with serpentine. The stone is distinguished by its soft and uniform texture, which admits of its being cut by the knife or saw, especially when freshly quarried, and also by its property of withstanding intense heat. Its colors are coarse gray and grayish green, sometimes yellowish; the texture generally granular; lustre dull; specific gravity 2.65 to 2.8; structure compact, sometimes lamellar; and to the touch it is greasy like soap. When crystalline or in thin and flexible foliæ of pearly lustre, it is commonly known as talc, of which the substance employed under the name of French chalk for removing grease spots is a variety. Meerschaum is another variety. The uses of soapstone are numerous, and beds of it furnishing large blocks unmixed with other substances are val-

table. Such are found at Grafton, Athens, Westfield, and Marlborough, Vt.; at Frances-town, Pelham, Keene, and other towns in New Hampshire; at Middlefield, Chester, and other places in Massachusetts; between Baltimore and Washington in Maryland; in Loudon co., Va., Guilford co., N. C., and numerous other places unworked on the range of the metamorphic rocks through the southern states.—The rock is sawed into slabs and used for jambs for fireplaces, for lining stoves, or for the whole stove. After being heated it takes a good polish and assumes an apple-green color. It is also turned in lathes for various articles, and is bored for water pipes; formerly it was much used for inkstands. The sizing rollers in cotton factories are made of soapstone, for which it is especially adapted from not being affected by acids nor liable to change of form by varying temperatures; the rollers are sometimes 4 feet long and 6 inches in diameter. The stone has been pulverized to be used with other materials in the manufacture of porcelain; it makes the biscuit semi-transparent, but brittle. The powder is especially useful as a lubricant for the journals of heavy wheels, and is also used as a polishing material for serpentine, alabaster, &c. It is the basis of cosmetic powders and of certain crayons. The spotted steatite, cut into cameos and calcined, assumes an onyx aspect. The softer varieties make excellent stoppers for the chemical apparatus used in distilling or subliming corrosive vapors. By the American aborigines soapstone was found to be a convenient and useful material for culinary utensils, and many of the ancient relics now met with are of this easily carved stone. The Chinese have employed it so generally for their idols and other figures connected with their religious rites, that it has sometimes been known as the "figure stone."

STEEL, a variety of iron, distinguished for the extreme and varying degrees of hardness of which it is susceptible, and for possessing at the same time the fusible property of cast iron and the malleability and welding property of wrought iron. Some notice of it has already been given under **IRON**, and some of its most remarkable properties are treated in the article **DAMASCUS BLADES**. In composition it holds a place intermediate between wrought or malleable iron and cast iron; the first being simply iron; steel, iron with 1 to 1½ per cent. of carbon; and cast iron containing about 4 per cent. of carbon. As the proportion of carbon in steel increases, the metal approaches cast iron in its properties, becoming hard and brittle, and increasing in fusibility; but with diminishing proportions of carbon it assumes more and more of the softness, toughness, and malleability of wrought iron. Those steels of the former character are designated as high, and those of the latter as low or mild. Other substances beside carbon, that are sometimes present to a very small amount, are commonly regarded as impurities; although some of them

exercise an important, and it may be at times a useful, influence upon the properties of the metal in its application to special purposes. Nitrogen, according to Prof. R. Marchand, is always present to the amount of about ½ per cent., associated with about 8 times as much carbon. In iron nitrogen is found by Schaufhäutl in proportions varying from 0.582 to 1.2 per cent., in white pig; and in all the processes of producing steel, as affirmed by Mr. C. Binks in a paper read before the society of arts in 1857, nitrogen in some form must be present.—The following are some of the properties of steel. When broken it exhibits in the fracture a grayish color, lighter than that of iron; its structure is granular, and in the best steel is very fine. This is produced by condensation by hammering or rolling, and is accompanied by a susceptibility of receiving a high polish, which is much less liable to be affected by rust than a polished iron surface. The metal is inferior to iron in ductility and malleability, and is worked down under the hammer or rolled with much greater difficulty. When balanced upon the hand and struck with a hammer, it gives a clear ringing sound, indicating by its peculiar intonation to the practised ear the quality of the metal. It acquires a higher degree of elasticity than any other solid body, and is hence best adapted for a great variety of springs. It is more slow than iron to become magnetic, but retains this property more tenaciously. Its melting point is given as 2,786° F., which is considerably higher than that of cast iron, and lower than that of wrought iron. It is not adapted for casting into moulds of intricate form, as well by reason of the high temperature of its melting point, as on account of its not thus acquiring the density and toughness which these forms may require, and which are imparted to steel bars by subsequent processes of hammering and rolling. Steel may be welded, but with more difficulty than wrought iron, especially if it has been first melted or cast; in this case a thin film of borax should be interposed between the surfaces to be united. A perfect union may be effected between wrought iron and steel by placing a bar of the former, with one surface well polished, in the mould into which the steel is cast. The two metals thus united, when rolled out, are sometimes employed for chisels, plane irons, &c., one face being of steel and forming the cutting edge, while the other being of iron insures the greatest toughness. A steel plate is rapidly cut by the edge of a disk of soft iron, made to revolve with great velocity. Intense heat is generated at the points of contact, and the particles of steel are thrown off in a state of ignition. The iron is very little worn or otherwise affected. Cast iron cannot be thus cut. The most striking peculiarity of steel is the different degrees of hardness it assumes by changes of temperature. When heated to redness and slowly cooled it is not much harder than iron, but by sudden cooling it is rendered very hard and brittle; and the higher

the temperature to which it is raised and the more sudden the cooling, the greater is the hardness. On this principle is based the process of tempering, by which any desired degree of hardness is obtained. The different temperatures are indicated by a succession of colors which the metal takes while heating, and these colors consequently serve to direct the workman who seeks to obtain the hardness that is appropriate for certain uses. Thus a very pale straw color, corresponding to 480° F., is the right color for lancets; a deeper shade, 450°, is adapted for razors and most surgical instruments; an orange yellow, 470°, for penknives; a brownish yellow, 490°, for cold-chisels; a brownish yellow tinged with purple, 510°, for plane irons; a purple, 530°, for table knives and scissors; a pale blue, 550°, for swords and watch springs; a common blue, 560°, for fine saws and dirks; very deep blue black, 600°, for pit saws. At 630° it becomes sea-green, but above this temperature the colors disappear, and if slowly cooled the steel becomes very soft, so that it can be worked with ease, after which it may be tempered as desired. A more exact method of tempering than by the color is to immerse the steel in heated baths of mercury or of oil, the temperature of which is carefully regulated according to the indications of the thermometer, graduated up to the boiling point of mercury. The cooling may be effected by plunging the articles into cold water, into cold mercury, or oil, or if they are very small by waving them through the air. By hardening steel its volume is increased.—The early history of steel is involved in much obscurity. It is supposed that the substance was known to the ancient Egyptians, and that articles made of it were designated in their drawings by a blue color. In the Hebrew language there is no word specially applicable to it; but it is supposed the hard "iron from the north," spoken of in Jeremiah xv. 12, may have been steel from Chalybia, a country famous for its iron production. There are several allusions in the old Greek authors to the hardening of a metal, commonly understood to be steel, by plunging it when hot in cold water; thus when Ulysses pierced the eye of Polyphemus with a burning stick, Homer describes the hissing as like that of red-hot iron when plunged by the smith into water to harden it. Aristotle describes the processes of the Chalybes by which they converted iron into steel, purifying it from the scoria by a succession of meltings. The word *στομαμα*, applied to the new product, is used by various Greek writers to designate something distinct from *σίδηρος*, iron, and, when described at all, having the peculiar hardness and uses of steel. Daimachus, a writer contemporary with Alexander the Great, names under the same designation four varieties of steel: the Chalybic, suitable for carpenters' tools; the Lacedæmonian, for files, drills, gravers, and stone chisels; the Lydian, for the same and also for knives and razors; and the Synopic. The Latin

writers called the same substance *acies*, and *ferrī acies*, whence the French *acier*, steel. Beckmann affirms on the authority of Hesychius that the term *adamās* originally meant steel, and should be so translated when applied to chains, bars, gates, &c. Yet it is remarkable that no articles of steel have been found among the relics of the nations of antiquity, even to the period of the Roman empire. The iron and steel of India are both mentioned by ancient writers, and the latter is supposed to be the same as the wootz, of which 100 talents, called *ferrum candidum*, were presented to Alexander in India, and which is still prepared there by a very primitive method. The Hindoos charge their crucibles with bits of malleable iron, mixed with wood and covered with the leaves of trees, which, when the metal is thoroughly heated, furnish the carbonaceous and nitrogenous elements of the steel. Fusion ensues, and the steel, of very superior quality for fine cutlery, is finally found in a button at the bottom of the crucible. During the middle ages the art of making steel existed in the highest perfection in Turkey and the countries of the East; but in western Europe it was comparatively little known. At Eisenärz in Styria it has been practised ever since the 8th century. Even as late as the 17th century few persons practised it in England, and the first patent granted for this manufacture was dated April 8, 1686, to Richard Lord Dacre, Thomas Letsome, and Nicholas Page, for "apparatus for making steel," according to the invention of Letsome. Foreign iron alone was used for it. About 1670 mention is made of steeling articles by "boiling them in sow-metal." The carbon of this is given up to the wrought iron articles in sufficient quantity to convert them into steel; and by Vanacio this was carried so far that the cast metal was also brought down to the steel point, making however poor steel. This is probably the same operation that is spoken of by Agricola, Imperati, and others, as practised at an earlier period on the continent. The manufacture by cementation is said to have been practised at Bromley by John Heydon as early as 1697, but was first made generally known by Réaumur, and described in his work on steel published in 1722 (see RÉAUMUR); and cast steel, it is stated, was first made by Mr. Huntsman at Attercliff, near Sheffield, in 1770. The subject attracted some attention in the Connecticut colony as early as 1655, when the assembly of New Haven granted privileges to John Tucker of Southold, Long island, who undertook the manufacture. There is no record however of his succeeding in it. Joseph Higby, an ingenious blacksmith of Granby, Conn., who also distinguished himself by his coinage of the Granby coppers, memorialized the legislature of Connecticut in 1727, that he had "with great pains and cost found out and obtained a curious art, by which to convert, change, or transmit common iron into good steel, sufficient for any use, and was the very

first that ever performed such an operation in America." He produced samples of good steel, and obtained a patent for 10 years.—Steel is obtained, first, either directly from iron ores, the carbon being infused into the iron as this is revived from the natural oxides; or, second, from cast iron, by removing from it a portion of the carbon it contains; or, third, from bar iron, by causing this to absorb a due proportion of carbon; and in procuring it from each kind of manufactured iron several processes are employed. From certain rich magnetic ores steel may be worked in a small way directly, even in the blacksmith's forge; and in the Catalan furnace the manufacture has been carried on upon a considerable scale. When this is the special object of the operation, the process of reduction is somewhat varied, with the view of checking the decarbonizing action before it is carried to the point of malleable iron. The operation is stopped at a point determined by experience, when the loop is removed and drawn out into bars under the hammer. By long continued hammering the steel thus obtained may be made to acquire a tolerably uniform density and composition; but a more expeditious method is to convert it into cast steel by melting in crucibles, in which condition it is kept from 3 to 4 hours, when it is poured out into cast iron moulds. The method is not largely practised, owing to the want of uniformity in the product.—Among the methods of treating cast iron for steel, that of partial refining by puddling has been long practised in Isère in S. E. France, in Thuringia, Westphalia, Styria, and Carinthia. What is known in this country as German steel, produced from pig iron made from spathose iron ores, is chiefly puddled steel carefully refined. In Isère the cast iron, usually gray, sometimes a sublamellar white iron, is first melted in a furnace with a single tuyère, together with rich scoræ of the preceding operation, with charcoal. The iron is slowly brought to the melted state, and is thus kept about 8 hours. The refining then commences, and lasts about 6 hours. The temperature is kept lower than in ordinary refining fires, just sufficient for the scoræ to remain in a fluid condition. The charge is worked up with a ringer, as in ordinary puddling, and the oxygen which removes the carbon from the cast iron is in part derived from the oxide of iron of the scoræ. To check its too rapid action the draught is diminished and silicious sand is thrown in. Steel "comes to nature" at the surface, forming a spongy crust. This is broken up, pushed toward the extreme end of the furnace, and formed into little loops of 80 or 40 pounds weight each. As these are produced about one every 10 minutes, they are taken out and hammered into blooms. About 8 hours are required to remove the whole charge of about a ton weight, making 22 hours for the whole operation. The blooms are afterward heated in a separate fire, and then drawn down into bars. About 132 parts of cast iron are

required for 100 of steel. In Westphalia lamellar manganese white irons, which are rapidly refined, are treated for steel in furnaces like the refinery fires. The cast iron is thrown in, in quantities of about 75 lbs. at a time, and when sufficiently refined the loops are taken out and drawn down under the hammer. The steel is used for making scythes, cutlery, and swords, after being well refined. In the New Jersey iron region, and in that of N. New York, puddled steel has been made to some extent. The best charcoal iron is required for the purpose, and manganese is sometimes added to the charge, the purpose it serves being apparently to lengthen out the time of the refining, and thus diminish the risk of passing the desired point of decarbonization. The process requires much care and skill on the part of the workman, and the product is rather a steely iron, or mixture of steel and iron, and this of varying and uncertain quality, than good steel. Whether puddled steel has ever been cast or not is uncertain. It is supposed that this may be done in Krupp's works at Essen, which will again be referred to. Other methods of treating cast iron for steel will be mentioned, after describing the process in general use of producing steel from bar iron. Nearly all the steel of commerce is prepared from bar iron by what is called the "cementation process." It consists in exposing the iron, buried in charcoal, to long continued heat. The operation is conducted in a furnace resembling externally that used in the glass manufacture, in the base of which, under an arch, are set two horizontal troughs made of fire slabs, each of them from 8 to 15 feet long, and from 26 to 36 inches wide and deep. Bar iron, made from magnetic ores with charcoal, is selected for making the best steel, and the English works are supplied with such iron from Sweden and Russia, the choicest brands being those known as hoop 1, \textcircled{D} ; GL, \textcircled{Q} ; and the double bullet, \textcircled{C} ; all produced from the ores of the famous Danemora mine. These irons are worth in England from £80 to £88 per ton, and, with other irons imported from Sweden, Russia, and Norway, are used in the manufacture of steel to the extent of 85,000 tons annually. The poorer English steel irons, worth £11 per ton, are used to the extent of about 20,000 tons. The bars are cut into lengths somewhat shorter than the troughs, and a bed for them being prepared in these about an inch deep, of pulverized hard wood charcoal mixed with $\frac{1}{4}$ its weight of ashes and a little common salt, the bars are laid in this edgewise, about half an inch apart. The charcoal mixture or "cement" is then sifted over the bars and pressed between them, so that each one is in contact with nothing else. When the bars are covered about an inch deep, another tier is added, each bar over the space between two bars of the bottom layer. The same packing with cement is repeated, and other tiers are added in the same manner,

till the chests are filled within 8 inches of the top. This space is then closed in with cement from a previous operation, and covered over either with damp silicious sand or with fire slabs, the joints plastered with fire clay. A complete charge is commonly about 15 tons; some furnaces hold 18 to 20 tons. In the end of the chests some of the bars in the centre are made to project through openings left for the purpose and through the brickwork in front, the object being to draw them out in the course of the process for indicating its progress. The fire is started and gradually increased for the first 24 hours, and after this the heat is kept at about 100° of Wedgwood's pyrometer, necessarily below the fusing point of steel. In 6 days the first examination is made, and in 2 more the bars are commonly found to be converted into blistered steel, so called from the blisters all over its surface, produced it is supposed by the insinuation of carbon beneath scales of the metal imperceptibly united to the mass; it has also been suggested that in the imperfectly welded places oxide of iron is formed, the oxygen of which uniting with the infiltrated carbon produces carbonic oxide and lifts up the metallic scale. The bars gain about $\frac{1}{10}$ in weight and about $\frac{1}{15}$ in length. From the manner in which the carbon is introduced, the steel cannot be homogeneous, but contains most carbon in its outer portions. If soft steel is wanted for springs and saws, the process may be stopped several days sooner than if a higher steel is required, suitable for files, chisels, and other cutting tools. The fire is stopped and the furnace is left for about two weeks to cool before the bars can be taken out. They may then be applied to a variety of ordinary purposes, as some agricultural instruments, table cutlery, coach springs, &c.; but to produce steel of good quality other operations are necessary. What is called shear steel, so named from its having been originally employed in the manufacture of shears for dressing woollen cloth, is made from fagoted pieces of bars of blistered steel, heated to a full welding heat, in which they are protected from oxidation by a coating of very fine clay, and drawn down under the tilt hammer to a bar two inches square, or any other desired size. The tilt hammer for finishing the small bars weighs only from 150 to 200 lbs., and is so constructed as to be worked with great rapidity, striking from 200 to 300 blows a minute, thereby keeping up the heat in the bar through the intense friction produced among the particles of the metal. Heavier hammers are also used, with heads faced with steel and weighing about a ton each. By this operation the steel is much condensed, and rendered of uniform quality and homogeneous structure throughout. Its tenacity, malleability, and ductility are increased, and it becomes susceptible of a high polish. By doubling the bar and repeating the operation the character of the metal is still further improved, and it is then known as double shear steel. The manufacture up to this point is carried on upon an extensive scale

in many large establishments in Sheffield, England, and both the blistered and shear steels are sold, to be converted by other manufacturers into the various objects of their operations.—But steel is carried to a still higher degree of perfection by another operation, which converts it into what is known as cast steel. This consists in melting in crucibles the bars of blistered steel, broken in pieces of a pound weight or less. The furnaces, one for each crucible, are partly sunk below the floor of the foundry, and are intensely heated by coke, or in the United States by anthracite. The largest measure about 20 inches by 16, and are 8 feet deep. The crucible, charged the first time used with 86 lbs. of metal, the second time with 82 lbs., and the third and last time with about 80 lbs., is introduced from the top upon the grate bars in the midst of the fuel; and the cover being put on the fire is driven by the strong blast derived from the high chimney, and kept up from 8 to 4 hours. The crucible is then lifted out, and its contents are poured into the cast iron ingot moulds. The ingots are hammered or rolled into bars or sheets, and the steel thus obtained is of the hardest and densest character, requiring much care in forging that it is not hammered at a heat above a cherry red, when it is in danger of being broken to pieces. It is made into bars of various shapes and qualities, and is very largely produced in Sheffield for domestic use and exportation. Great care is taken to insure a uniform quality in each sort of steel sent to market, and also the exact quality suited to the particular use for which the steel is designed. Each ingot is not only examined to insure its uniform character, but it is also appropriated to the special use for which, according to its tenacity and hardness, it is found to be adapted. Many important tools require a particular grade of steel, and constant practice and long experience are necessary to appreciate the differences of quality. But notwithstanding all this care large lots are occasionally returned to the makers by manufacturers in this country, who find the steel ill adapted to their purposes, although from the same houses that have previously supplied them satisfactorily. It is not strange then that consumers are unwilling to incur the risk of trying a new variety, especially when so many instances are before them of failure on the part of novices to produce continuously good steel of uniform quality. Every one therefore who engages in this manufacture does so in the face of serious difficulties, not merely in producing a good article, but in getting it recognized as such, and a sale established for it. The most important improvement introduced of late years in the manufacture resulted from the experiments of Mr. Heath of Sheffield, who sought to produce with English iron steel like that made with the Swedish. The great difference in their qualities, it was thought, might be owing to manganese, which was always present in the Swedish iron. In

1839 he succeeded in producing a carburet of manganese, which caused the English iron to make good steel. He patented the process, but not the improvement he made upon it of using the carbon and manganese separately. This the Sheffield manufacturers adopted, and between 1839 and 1855 it has been estimated that the saving to the buyers of Sheffield cast steel goods by reduced prices in consequence of this invention has been equal to £2,000,000. But Mr. Heath was no more benefited than was Cort for introducing the puddling process; and he died in 1850 poor and broken-hearted.—Among the new processes of making steel, that of Bessemer (see IRON MANUFACTURE, vol. ix. p. 607) has attracted the greatest attention. It appears to be still on probation in Europe, and is spoken of as being tested in works especially built for the purpose in Sheffield. Little is stated as to the cost of the steel made by this process, or of its uniformity of character; but some of the steel produced by it possesses a wonderful tensile power. A bar 3 inches square was bent round until the outer curve was lengthened from 12 to 16½ inches, and the inner lessened from 12 to 7½ inches, cold and without a flaw. Four iron rods, 1½ inches in diameter, were twisted cold into a cable; the rods stretched 1 foot in 4 during the process, and thinned out in inverse proportion. A steel bar 2 inches square was twisted cold into a spiral at an angle of 45°. A round steel bar was hammered cold into the form of a horse shoe. The manufacture of steel by this process is reported to be carried on in several localities in Sweden, especially by Daniel Elfstrand and co. of Edsken; and by Mr. Göranson of Gefle in Sweden large steel circular saw plates have been made from ingots cast direct from the fluid metal within 15 minutes of its leaving the blast furnace. The old firm of James Jackson and son near Bordeaux, France, is also reported to have adopted this process in preference to the manufacture of steel by puddling; and it was also about being adopted at 4 blast furnaces belonging to other establishments in the south of France. In Belgium and Sardinia it was also about being introduced.—What is known as the Uchatius process was introduced in 1856 by Captain Uchatius, engineer of the imperial arsenal at Vienna, and consists in melting in crucibles cast iron reduced to small particles and intimately mixed with some compound of iron and oxygen. Brown spar or the spathose protocarbonate of iron, with some oxide of manganese, was found to be well suited for the purpose. The quantity of oxide is graduated to furnish just the amount of oxygen required. The cast iron is granulated by causing it, as it flows from the blast furnace, to be dashed and scattered by the floats of a wheel from which it falls into cold water, and the smallest pieces are preferred, even such as weigh 1,000 to the pound. The most intimate mixture is thus effected, and the chemical change takes place most readily and thorough-

ly, resulting in homogeneous steel of the softest quality. As the oxide of iron gives up its oxygen to carry off a portion of the carbon from the cast iron, it is itself reduced to the metallic state, and adds to the quantity of steel obtained, which is thus somewhat greater than of the cast iron employed. The mixture for producing 25 lbs. of steel consists of 24 lbs. of granulated iron, 4 lbs. of spathose ore, 4 lbs. of oxide of manganese, and a little clay. The conversion is completed in 2 to 8 hours, when the steel is poured into the moulds. The method is improved for irons of inferior quality by adding a portion of alkaline earths to the charge, the effect of which is to remove the impurities which readily combine with these as the granules melt.—Other methods of decarbonizing cast iron to the steel point are also practised. One consists in melting together proper proportions of bar and cast iron for the carbon contained in the latter to produce the sort of steel desired, when it is divided throughout the whole of the iron. A patent was granted for it a few years since to G. Brown, of Swinton. He mixes in a crucible small pieces of charcoal, with pieces of bar iron and of pig iron. For a 40 lb. ingot, the proportion of cast iron varies from 7 to 12 lbs., according to the sort of steel, mild or high, required. The great proportion of the charge is necessarily bar iron, and whenever this is to be melted great expense is incurred in crucibles, the best standing only 2 or 3 heats. The best sorts of iron must be employed, there being no provision for separating and removing the noxious elements usually present.—A method of converting malleable iron into steel by fusing it in the presence of an alkaline cyanide, has within a few years past been introduced into practice upon a large scale in the vicinity of New York. For a long time it has been known to workers in steel and iron that the latter might be superficially hardened by fusing upon it the cyanide of potassium; but it was not known that steel might thus be made in the large way until the fact was demonstrated by Prof. A. K. Eaton, who, while lecturing upon chemistry at Little Falls, N. Y., was led to engage in a course of experiments in this direction. He first studied the action of cyanogen, a gaseous compound of carbon and nitrogen, upon incandescent iron; and then of the solid compounds of this gas in the form of the cyanide or ferrocyanide of potassium (prussiate of potash) and cyanide of sodium. He found that iron raised to a bright red heat in a porcelain tube, or otherwise protected, was rapidly and perfectly converted into steel, by passing over it cyanogen gas; also that iron wire introduced into the flame of a burning jet of cyanogen was similarly changed by absorption of carbon. Bars of iron were then packed in fine charcoal with an admixture of yellow prussiate of potash or other cyanide, and at a high temperature these in a surprisingly short time were thoroughly converted into steel. The object of the charcoal is explained

by the following *rationale* of the operation: When cyanide of potassium, which consists of two atoms of carbon and one each of nitrogen and potassium, is decomposed at a high temperature in contact with iron by reason of the affinity of its carbon for the iron, the nitrogen would be set free, but that in the presence of ignited carbon and an alkaline base it always will combine with these to produce cyanide of this base. In this case, an atom of potassium being released, all the conditions are favorable for this reaction. Thus the charcoal is added to reproduce the cyanide of potassium as fast as it is decomposed; and the action of this salt is as a carrier to convert the charcoal into the proper condition required for its being taken up by the iron. These and other experiments led to the charging of melting pots with bits of malleable iron and a mixture of cyanide salts and powdered charcoal. After melting, the product turned out into ingot moulds was found to be cast steel, which, by the ordinary method, was then drawn into bars. The process proved to be more expeditious and economical than any before applied to the manufacture of steel. In 1851 and 1852 its practicability was demonstrated upon a large scale, first at Rochester and afterward at New York, and its application to the reduction of iron ores and the production of steel direct from the ore tested. At this stage of the history of the process Prof. Eaton disposed of his interest in it to other parties, who directed their attention wholly to attempts to work by means of it the ores of iron. They neglected to patent the process, and some time afterward application was made and obtained for a patent by an individual who, while the demonstrations were made in New York, had an opportunity of obtaining knowledge of the materials employed. Thus the discoverer and original proprietors lost the exclusive control of this method of making steel. Under the patented process another salt (sal ammoniac) has been used, which, however, can have no effect upon the result, as it volatilizes at a temperature much below that at which the other ingredients of the mixture are affected. The manufacture is now carried on in New Jersey and on Staten island by the owners of the patent; and works are about to be started at Pittsburg. The process, however, is incumbered with the objection that it is necessary to employ the choicest kinds of American bar iron, in order to produce cast steel of a uniform good quality; and to the still more serious difficulty arising from the rapid destruction of the costly melting pots in which the malleable iron is fused. These rarely stand more than two or three meltings, and some only one, before they are rendered worthless. The quality of much of the steel produced is fully equal to the best of English manufacture, so that its use has been adopted in several of the important mines of Lake Superior, where the consumption of steel is very great, and also in numerous quarries and machine shops for

the various tools employed.—Processes were afterward invented by Prof. Eaton for converting cast iron into steel, which are particularly applicable to moulded objects, the form of which it is desirable to retain in the condition of steel. The castings adapted to this operation are such as are employed in the ordinary manufacture of malleable iron castings, being prepared from those mixtures of pig iron which produce a silver-white high iron of great hardness, and such fluidity when melted as to take the minutest impressions of the mould. By boiling these in fused carbonate of soda, Prof. Eaton found that the carbon of the cast iron was gradually removed, proceeding from the outside of the articles toward the centre, and that, according to the stage of the operation at which the articles were taken out, they might be obtained in steel of any desired grade of hardness or proportion of carbon, test bars of suitable thickness introduced into the pot with the articles to be converted and taken out from time to time indicating the progress of the operation. Bubbles of carbonic oxide rising through the boiling soda indicate that the process of removing the carbon is still going on. The pot employed is of cast iron, an inch or more thick, and the boiling is kept up for about 70 hours to produce the change throughout a thickness of about an inch. The effect of the carbonate of soda is not merely to combine with and remove the carbon from the iron, but any sulphur, silicon, phosphorus, &c., present are taken up, and the metal is freed from these impurities so detrimental to steel. The process was found well adapted for the rapid production in steel of multiplied copies of the same article, especially of those which by reason of their irregular figures it would be difficult to forge, such as plough points, &c.; while it was also well suited to others, as hoes, shovels, &c., which, being cast in small thick plates and converted, might then be rolled out, the tang properly shaped, and the finish given without the necessity of riveting or welding separate pieces together. Bars of cast iron have also thus been converted into excellent steel and used for cutlery. The forging after converting no doubt has the effect of giving greater diversity to the metal, although the converted steel presents no indications of deficiency in this respect. If necessary, articles cast in the shapes they are to retain may be rendered more dense by compressing them in dies.—Carbonate of soda was found to be much more efficient than the hydrate, and this led to experimenting upon the effect of carbonic acid gas as a decarbonizing agent. In the bottom of a vertical cylindrical retort were placed bits of limestone, above these pieces of cast iron, and from the top proceeded an open tube for the escape of the gases. The retort was so arranged in the fire as to receive the heat chiefly in its middle portion, all that was required at the bottom being enough to slowly expel the carbonic acid from the limestone. When the retort was heated, the gas that

escaped proved to be inflammable, burning with the blue flame of carbonic oxide, and was evidently produced at the expense of the carbon of the cast iron, which furnished an atom to each atom of carbonic acid from the limestone. The diminution of the inflammable gas indicated the removal of most of the carbon, and the process being stopped, the cast iron was found to be converted into good steel. To protect delicate castings from being bent at the high temperature required, they are advantageously packed in some coarsely powdered substance; and oxide of iron, such as is used in the ordinary malleable iron process, is especially well suited to this purpose; for, beside accomplishing this object, it readily gives up oxygen to carbonic oxide at high temperatures, converting this back to carbonic acid in twofold quantity, and this is immediately ready to renew its decarbonizing action upon the castings with multiplied effect. By calculation, the quantity of carbonic acid required to decarbonize any amount of cast iron, the composition of which may be assumed as represented by the formula Fe_3O_4 , is as 66 to 690, the latter being the weight of the iron; but if 160 lbs. of peroxide of iron be added, the first effect should be to produce 182 lbs. of carbonic acid, which should decarbonize twice the original amount of cast iron. The following modifications have hence been recommended in the manufacture of steel by the soda process: 1st, the use of the bicarbonate of soda, in place of the simple carbonate; and 2d, the passing of a current of free carbonic acid through or over the bath of melted soda containing the cast iron, in order that the soda may be recarbonated as fast as its carbonic acid is decomposed by the cast iron. Common salt is advantageously added, considerably reducing the bulk of soda required. In case of the process having been carried so far as to render the external portion too soft, Prof. Eaton rehardens this portion by immersing the articles for a short time in a bath of fused prussiate of potash. He finds that merely keeping them at a high temperature in a furnace tends to distribute the carbon they contain uniformly throughout the mass. It is recommended to make use of the final product of carbonic oxide generated in this process, as a reducing agent of the native oxides of iron. For this purpose the gas may be led into a second retort charged with these oxides, and there being reconverted into carbonic acid by its reaction upon the oxide, this gas may be returned to the decarbonizing retort to go again the same round. The use of these processes was secured to Prof. Eaton by patent, June 25, 1861.—The great importance of the manufacture of steel in England is shown by the following statement of its condition in 1853. It is there carried on chiefly in Sheffield and its neighborhood, where there were at that time 160 converting furnaces of a capacity of 800 tons of bar steel per annum, and 1,496 melting holes for cast steel capable

of melting, for each furnace of 10 holes, 200 tons. The actual product has been estimated at 40,000 tons of bar steel, producing 23,000 tons of cast steel, 10,000 tons of coach spring steel, and 7,000 tons to be converted into German, fagot, and single and double shear steel. The commercial value of the cast steel varies from £35 to £60 per ton, averaging about £45. The price of the bar steel varies from £28 to £60 per ton, and the rate of £35 per ton, given in the table below, is probably under the average. Coach spring steel is £19 per ton. The whole may then be rated as follows:

23,000 tons of cast steel, all qualities at £45 per ton	£1,035,000
7,000 tons of bar steel, including German, fagot, single and double shear steel, average £35 per ton	245,000
10,000 tons of coach spring steel, £19 per ton	190,000
40,000 tons	£1,470,000

This is somewhat increased by the other operations carried on at Newcastle and in Staffordshire. The production of other countries is stated in the following table, which we take from the new edition of "Ure's Dictionary" edited by Robert Hunt:

Countries.	Tons.	Average value.
France	14,954	£443,850
Prussia	5,408	170,824
Austria	18,087	831,073
The United States	10,000	212,500

Concerning the production in the United States no correct statistics have been collected, and the estimate just named can certainly not be applied to steel of original manufacture. There are many small establishments in Pittsburgh, Philadelphia, New Jersey, and New York, in which scrap steel is remelted, and some cementation steel is produced at a few places in different parts of the country for the use of those who manufacture it; but American cast steel is hardly known in the markets. The Adirondac manufacture noticed in ADIRONDAC MOUNTAINS has ceased, and some others also in New Jersey. Some cast steel is, however, made in the works in Jersey City; and at Rockaway, N. J., it is produced to the extent of about a ton a day. In Connecticut also there is a manufactory of about the same capacity. There is one establishment in operation on Staten island, N. Y., which made about 800 tons of steel in 1861, and has a capacity of production somewhat larger. There is another, also employing the cyanide process, at Pittsburg, Penn., and making 500 tons or more per annum. Thus the total production of cast steel appears not to exceed 2,000 tons; and that of blistered steel, to be used without melting, is probably not much more. The great abundance of ores which we possess, as well adapted for this manufacture as those of Sweden and Norway, must ere long render us independent of all foreign competition in the production of this important article. The importations of steel into the United States, not including cutlery and saws, were as follows for the years ending June 30, 1859, and June 30, 1860:

—Although England exceeds all other countries in its production of steel, the largest manufactory in the world is probably that of F. Krupp of Essen, in Rhenish Prussia. It is situated in the midst of coal mines, and covers with its buildings and yards a space of 1,600 by 1,800 feet; the roofs of the buildings cover 20 acres. It employs 2,800 to 2,500 men, and consumes more than 200 tons of coal each day, and 49,000 feet of gas for lighting the works. The process employed has not been made public; but the products have attracted great attention in Europe, from their unparalleled size. They consist of steel cannon, steamboat and other shafts, railroad axles and tires, and machinery, rolls for mints, &c. At the Paris exhibition of 1855 there was a mass of steel from these works of 10,000 lbs. weight, and another piece has been produced of 20,000 lbs. weight. A steel shaft for a French steamer was made 30 feet long, at a cost of \$6,000. The largest casting made is of 40 tons weight, but the works are competent to make much heavier ones. Of the steel car axles it is reported that Mr. Krupp pledges himself to pay \$10,500 if any that he sells breaks within 10 years. The heaviest hammer weighs 40 tons. A steel cannon is to be exhibited in London in 1862 of 10-inch bore, the casting of which requires the labor of 1,250 men in pouring the metal into the mould. Many steel cannon have been produced for the European governments, and three small ones have been sent to this country for the city of Philadelphia. The manufacture of cannon from puddled steel was commenced in New York in 1861 on the plans devised by Mr. Norman Wiard, and the first piece was completed and ready for service on July 1; since which time many more, chiefly 6 and 12-pounders, with some 50-pounders, have been completed, and have done efficient service in the campaigns in the South and West. The steel is puddled at the rolling mills in Troy, N. Y., and Trenton, N. J., the process being stopped at the point when sufficient carbon remains in the metal to give it the steely character. The metal is then hammered into blooms, and is taken to New York, where it is forged in the works of Messrs. Tugnot and Dally; after which the solid

pieces are bored and rifled by Messrs. Plass and co. The largest gun made up to April, 1861, is of 5.1 inches caliber, and weighs 6,000 lbs. Pieces found defective on trial tests are only about one to the hundred. The tensile strength of the steel is said to be equal to a strain of from 107,000 to 118,000 lbs. to the square inch. —Many of the applications of steel to useful purposes have been incidentally alluded to in the course of the present article. These are very numerous, and are constantly increasing, as the methods of manufacture are improved. When produced in a small way by imperfect and difficult processes, its use was confined to cutting tools and important instruments that required great hardness, strength, or elasticity. In many its use was economized by making only the part subjected to wear of steel, and welding this to iron; and the practice is still retained to some extent, as in axes and other heavy tools; while in others, as the drills and hammers which consume immense quantities of steel in mining and various manufacturing operations, it has been found more advantageous, at least in the United States, to use cast steel exclusively. Its applications to cutlery are quite as successfully conducted in this country as in any part of the world. But for the material itself we are chiefly dependent upon Great Britain; also for the plates used for saws and steel pens, as noticed in the articles on these subjects. Plates for engraving require an excellent variety of steel specially prepared for this purpose. Springs of all sizes, from the hair springs of watches to the heaviest used upon steam carriages (see SPRINGS), consume it in large quantities. Steel wire is made to some extent for springs, musical instruments, needles, &c. Having about three times the strength of iron wire of the same size, it is advantageously employed for making ropes for special purposes. The application of steel to cannon is of great importance from the large saving in weight over cast or wrought iron compatible with the same strength. This branch is yet in its infancy, and is carried on to any extent only at the works of Mr. Krupp at Essen. The same may be said of car axles, shafts for steamboats, &c. The sonoroussness of steel

renders it a suitable material for bells; some of large size have been made in England, one of which is in use at San Francisco, California. For the effect of tungsten in combination with steel, see **TUNGSTEN**.

STEEL ENGRAVING. See **ENGRAVING**.

STEELE, a S. E. co. of Minnesota, drained by the Lester river and branches of Cannon river; area, 432 sq. m.; pop. in 1860, 2,868. The surface is undulating, diversified by prairie and strips of forest, and the soil fertile. There are 3 or 4 small lakes and a number of fine streams of water. In 1859 there were 32 schools. It is on the line of the projected Transit railroad. Capital, Owatona.

STEELE, **SIR RICHARD**, a British author born in Dublin in 1675, died at Llangunnor near Caernarthen, Wales, Sept. 1, 1729. His father was secretary to the duke of Ormond, lord lieutenant of Ireland, and through the influence of that nobleman young Steele received his early education at the Charterhouse, where his intimacy with Joseph Addison was formed. In 1692 he entered Merton college, Oxford, but left at the expiration of 3 years without taking a degree, in the hope of obtaining a commission in the army. His friends discountenanced the idea, and a relative in Ireland, who had named him heir to a large estate, threatened to disinherit him if he carried it into effect; but Steele, having made up his mind to be a soldier, enlisted as a private in the horse guards, and was accordingly disinherited. His genial humor and ceaseless flow of animal spirits made him a general favorite, and he was promoted to a cornetcy, and subsequently to a captaincy in Lucas's fusiliers, the latter appointment being due to his colonel, Lord Outta, to whom he had dedicated "The Christian Hero" (1701), a little book written when the author was "deep in debt, in drink, and in all the follies of the town," to strengthen his mind in habits of religion and virtue. In odd contrast to this work appeared in the succeeding year his comedy of "The Funeral, or Grief à la Mode," which had great success, and was followed by "The Tender Husband" and "The Lying Lover." The latter, as Steele some years later informed the house of commons, was "damned for its piety;" but the author, who had by this time become a fashionable man upon town, readily turned his talents into other channels, and for many years wrote nothing more for the stage. He took his place among the wits of Queen Anne's reign, was appointed gazetteer and gentleman usher to Prince George of Denmark, and, with ample means derived from two marriages, the second of which took place in 1707, he lived constantly beyond his income, was often in pressing need of money, and never free from fear of the bailiffs. Amid the most reckless dissipation, he was invariably good-natured and amiable, and his follies were usually succeeded by severe contrition, which however would not prevent him from transgressing as deeply the next day.

His life, in fact, as he has himself expressed it, was passed in "sinning and repenting." Availing himself of the hint afforded by Defoe's tri-weekly paper, the "Review," he commenced in 1709 the "Tatler," for which Addison furnished many of the leading papers, though by no means so many as Steele, whom he now assisted to the appointment of a commissioner of the stamp office. With the overthrow of the whigs in 1710 he lost his office of gazetteer, and with it the means of supplying the items of official news which at first formed an important feature in the "Tatler." This paper was accordingly succeeded in 1711 by the "Spectator," written chiefly by Steele and Addison, and subsequently by the "Guardian," begun and ended in 1713, and a variety of similar periodicals, some of which enjoyed but a brief existence. In 1718 Steele was led, through dissatisfaction with ministerial measures, to resign his office, and was returned to parliament from the borough of Stockbridge, in Hampshire; but having been arraigned before the bar of the house of commons for writing articles in the "Crisis" and the "Englishman," "maliciously insinuating that the Protestant succession in the house of Hanover was in danger under her majesty's administration," he was adjudged to be guilty of a scandalous libel, and was expelled by a vote of 245 to 152—the whole proceeding being, according to Lord Mahon, "a most fierce and unwarrantable stretch of party violence." His pen, however, continued to be actively employed in the whig interest, and upon the accession of George I. he received several profitable appointments, including that of governor of the royal company of comedians, was knighted by the king, and elected to parliament from Boroughbridge. No accession of means however seemed to better his fortunes, and while holding half a dozen offices, and commanding the admiration of the town by his talents, he was frequently reduced to the most pitiable pecuniary shifts. Having opposed the court measure for fixing permanently the number of peers, he was deprived by the lord chamberlain of his license for acting plays, whereby, according to his own account, he sustained a loss of nearly £10,000. In 1721 he was reinstated in his office, and produced in the succeeding year his last and best comedy, "The Conscious Lovers," which proved completely successful, and brought him in ample receipts. He was nevertheless reduced soon after to the necessity of selling his share in the playhouse in Drury Lane, the proceeds of which were speedily consumed by extravagance and an unsuccessful lawsuit with the managers. At this juncture a paralytic attack rendered him incapable of further literary labor, and he retired to a small estate near Caernarthen in Wales, left him by his second wife, where he died almost forgotten by his contemporaries, having "outlived his places, his schemes, his wife, his income, his health, and almost every thing but his kind heart." Although the fame of Steele

as an essayist is somewhat overshadowed by that of his literary coadjutor, Addison, he possessed perhaps the more fertile imagination of the two, and is entitled to the credit of having first conceived the characters of Sir Roger de Coverley, Will Honeycomb, and others of the Spectator club, which received their finishing touches from the hand of Addison. He was distinguished by a chivalric admiration of women, and his letters to his wife, about 400 in number, form one of the most singular correspondences ever published. There is an elaborate treatise on the character and genius of Steele in Forster's "Historical and Biographical Essays" (2 vols., London, 1858); and Thackeray, in his "Lectures on the English Humorists," has treated the same subject at length. The writings of Steele have never been collected.

STEELYARD. See **BALANCE**.

STEEN, JAN, a Dutch painter, born in Leyden in 1686, died in 1689. He early rose into great reputation as a humorous painter, throughout life was addicted to good living, and is even said to have opened a public tavern. His pictures represent merrymakings, card parties, tavern interiors, alchemists' laboratories, schools, sick rooms, &c. According to Kugler he was almost the only artist of the Netherlands who brought into full play all the elements of genuine low comedy. Fine specimens of his powers are to be found in private collections in England, but the greatest number of his works are in the museums of the Hague and Amsterdam. That of the Hague contains the well known picture entitled a "Representation of Human Life." He painted in all about 800 pictures.

STEERING APPARATUS, the appliances by which vessels are guided through the water. The earliest method was by a long oar passed out of the stern. Sometimes more than one were used for this purpose, as is seen in the drawings of some of the ships of the ancient Egyptians. An oar is a very efficient means of steering boats, and is still employed on such as often require sudden turning or the exertion of considerable force to bring the boat round, as on some canal boats, whale boats, rafts, &c. The principle of the rudder is explained in the article **SHIP**, vol. xiv. p. 601. The head of the rudder, projecting above the deck, is furnished with a horizontal handle or lever called the tiller, by which the rudder is turned. The term helm is often applied to this, as also to the rudder and tiller together. As by reason of the motion of a vessel through the water a powerful force is exerted to keep the rudder on a line with the keel, and as by the shock of the waves the rudder is sometimes violently thrust to one side or the other, it becomes necessary on small vessels to steady the tiller by a rope made fast to the weather side of the vessel, and one end held with a turn around the tiller. A block and tackle are required for vessels of larger size, replaced upon still larger ones by "the wheel." This is a wheel and axle set upon the tiller, the rope of which,

making several turns round the axle, is carried toward each side of the ship, so that the turning of the axle draws the tiller toward that side the rope of which is being wound up. The handles for working the wheel appear as spokes extended beyond the periphery. About the year 1802 boats were used on the Forth and Clyde canal with the steering wheel fixed forward and connected with the rudder by ropes, chains, or rods. Though this plan did not continue in use in Europe, it necessarily followed the construction in the United States of the long river steamers, the decks of which are obstructed with cabins and machinery, and the wheel has been set in these in the most conspicuous place forward, in a sort of tower called the pilot house. In consequence of serious disasters having occurred from the ropes leading to the rudder being burned in case of fire, it is now made a law that chains or iron rods shall be used for this purpose. Large vessels require several men at the wheel in rough weather; and the very largest appear to have fallen short of due efficiency in their steering apparatus, and of the necessary power for working it. Steam engines specially devoted to this work may yet be found indispensable. By the use of 2 screw propellers, one each side the rudder, it is found by Mr. Edwin A. Stevens of Hoboken, N. J., that when these are worked in opposite directions the vessel may be turned on its centre as a pivot, and he has adopted this plan, which is the most efficient steering apparatus known, for the "Stevens battery." (See **BATTERY**, and **SHIP**.)

STEEVENS, GEORGE, an English author and Shakespearian editor, born at Stepney in 1786, died at Hampstead in Jan. 1800. He was educated at Eton and at King's college, Cambridge. His first publication, a reprint of "Twenty of the Plays of Shakespeare, being the whole Number printed in Quarto during his Lifetime" (4 vols. 8vo., 1766), contained, in addition to a faithful reprint of the original text, a variety of readings from other quarto editions, given in the foot notes; and the reputation which he thereby acquired led to his association with Johnson in the preparation of the edition of Shakespeare which was published in 1773 with their joint names. Their 2d edition appeared in 1778, and two years later Malone, who had rendered Johnson and Steevens some assistance in its preparation, published a supplement containing the doubtful plays and the poems. Steevens, who regarded this almost in the light of a challenge, immediately set to work upon a new edition of Shakespeare, which occupied him, in conjunction with Isaac Reed, incessantly during the next 12 years. Disregarding the principles which had guided his former labors, he aimed at preparing a text which, "instead of a timid and servile adherence to ancient copies," should be distinguished by the "expulsion of useless and supernumerary syllables, and an occasional supply of such as might fortuitously have been

omitted." The edition was published in 1798 in 15 vols., and until the appearance of that of Knight in 1838 maintained its reputation as the standard text, although in the edition of Malone, published posthumously by Boswell in 1821, some attempts were made to adhere to the early copies. Steffens's remaining productions are of little importance, if we except his anonymous contributions to the "St. James's Chronicle" and the "Critical Review," in which he attacked many of his literary contemporaries, for whom in private he professed admiration and esteem, in language surcharged with biting sarcasm. He was characterized by Johnson as "mischievous" rather than malignant. He appears in a less amiable light when foisting upon the mock commentators, Amner and Collins (names invented by himself), annotations he was ashamed to acknowledge as his own; or when appending the name of his rival, Malone, to a bitter attack upon Capell.

STEFFENS, HENRIK, a German author, born at Stavanger, Norway, May 2, 1778, died in Berlin, Feb. 13, 1845. He studied theology at Copenhagen, then devoted himself to the natural sciences, and became a disciple of Schelling. He was intrusted in 1800 with the revision of Schelling's writings on the philosophy of nature. He soon after enjoyed at Freiburg the friendship and instruction of Werner, and wrote his *Geognostisch-geologische Aufsätze*, afterward expanded in his *Handbuch der Oryktognosie* (3 vols., Halle, 1811-'19), in which nature is considered historically as a spiritual force representing itself in time. He lectured with applause in Copenhagen in 1802; accepted a professorship at Halle in 1804, where he wrote his *Grundzüge der philosophischen Naturwissenschaft* (Berlin, 1806); lived with friends in Holstein, Hamburg, and Lübeck from 1807 to 1809; was involved at Halle in the dangerous schemes of Prussian patriots for throwing off the French yoke; went to Breslau in 1811, where his addresses animated the people and especially the students in the war against Napoleon; and, having volunteered in the army, marched with it to Paris. He returned to Breslau, where he held the chair of physics and of the philosophy of nature, till in 1831 he was called to a similar professorship in Berlin. According to Michelet, "the totality of the school of Schelling is most manifestly set forth in his writings." In his *Anthropologie* (2 vols., Breslau, 1822) he carried abstract philosophy into the domain of physiology, treating the constitution of human nature in its relation to that of the universe. He discussed practical questions and the philosophy of politics and society in *Ueber die Idee der Universitäten* (1809), *Die gegenwärtige Zeit und wie sie geworden* (2 vols., 1817), and especially the *Caricaturen des Heiligsten* (2 vols., 1819-'21). He opposed in the interest of a philosophical pietism the evangelical union, and published the polemical treatise *Von der falschen Theologie und dem wahren Glauben* (1824), and the confession of

faith *Wie ich wieder Lutheraner wurde* (1831). He embodied his reminiscences in a series of novels, *Walseth und Leith* (1827), *Die vier Norweger* (1828), *Malcolm* (1831), and *Die Revolution* (1837). His heroes are chiefly Scandinavians, who travel southward, become involved in the events of the French revolution and in German theories, and bestow their admiration in turn upon the worship of genius, Moravian piety, Prussian heroism, Schelling's philosophy, and Werner's geology. His last work was an autobiography, *Was ich erlebte* (10 vols., 1840-'45). His *Nachgelassene Schriften* appeared with a preface by Schelling in 1846.

STEIN, CHRISTIAN GOTTFRIED DANIEL, a German geographer, born in Leipsic, Oct. 14, 1771, died in Berlin, June 14, 1830. He was educated at the university of Leipsic, studied theology, but gave special attention to geography and statistics, and in 1795 became teacher of those branches at the gymnasium of the Grayfriars in Berlin, with which he was connected during the remainder of his life. His works, geographical, historical, and statistical, for schools, including an "Atlas of the Whole World" (25th ed., Leipsic, 1850), have obtained a wide popularity.

STEIN, KARL, baron von. See ALTENSTEIN.

STEIN, LUDWIG, a German political economist, born in Eckernförde, Schleswig, Nov. 15, 1818. He was the child of poor parents, and was educated at the expense of Frederic VI. of Denmark. His first work was a "History of Civil Process in Denmark" (Kiel, 1841); his second, *Der Socialismus und Communismus des heutigen Frankreich* (Leipsic, 1844), of which a 2d edition, remodelled and considerably enlarged, has appeared under the title of *Geschichte der socialen Bewegung in Frankreich von 1789 bis auf unsere Tage* (3 vols., Leipsic, 1849-'51). He has also published *Französische Staats- und Rechtsgeschichte* (3 vols., Basel, 1846-'8). In 1846 he was appointed professor of law in the university of Kiel, and joined in a protest against the threatened infringement of the rights of Schleswig by the Danish crown. In 1848 he was appointed by the provisional government of Schleswig envoy to Paris. Having been deprived of his professorship, he received the chair of political economy in the university of Vienna, where he has since resided. He is now engaged upon a comprehensive work entitled *System der Staatswissenschaften*. He is a zealous free-trader.

STELLIO (Daud.), a genus of iguanian lizards, characterized by a triangular, flattened head, covered with numerous small spinous plates; body depressed, the scales having intermixed some larger and rougher plates; a longitudinal fold on each side between the legs; no femoral pores, and no dorsal or caudal crest; anal pores distinct; tail with large keeled and spiny scales arranged in whorls; incisors 4 above, canines 2 above and none below, and cheek teeth triangular; no teeth on palate; tongue thick and fleshy. The common stellio

(*S. vulgaris*, Daud.), the *lacerta stellio* of Linnaeus, the *hardun* of the Arabs, is about a foot long, of which the tail is not quite one half; the color is olive, shaded and spotted with black above and olive yellow below. It is common in the Levant, and especially in Egypt, where its excrements were formerly collected and used in making cosmetics; it is a very active animal, feeding on insects, and living in ruins, clefts of rocks, and holes in the ground. According to Ouvier, Mohammedans always kill it, thinking that it purposely insults them by bowing its head in imitation of their motions during prayers. The *stellio* of the ancients was undoubtedly a species of gecko, and probably the *Pt. Hasselquistii* (Dum. & Bibr.). (See GACKO, vol. viii. p. 119.)

STENDHAL. See BEYLE.

STENOGRAPHY, a method of abbreviating ordinary writing by the use of signs, now almost universally superseded by phonography or phonetic shorthand. (See PHONOGRAPHY.) Some writers assert that Xenophon used it for reporting the conversations of Socrates, but it is uncertain whether any system had been invented prior to the time of Cicero, whose freedman Tiro is said to have by this means reported some of Cato's speeches. It was extensively practised during the early period of the Roman empire, but was entirely abandoned in the dark ages. In England the first attempt at stenographic writing dates from 1602, at which time John Willis's alphabetic system was published, though a system of characters representing words had appeared in 1588, invented by Timothy Bright. Several other writers followed Willis, the most famous of whom was Rich, whose system, amended by Dr. Doddridge, has come down to our own time. In 1682 Mason published a better and simpler alphabet, which was the most popular for a century. Its modification by Thomas Gurney (1758), known as Gurney's shorthand, has been employed by his descendants as parliamentary reporters up to the present day. The systems of Byrom (1767), Taylor (1786), Mavor (1789), and Lewis (1815) have each had their advocates, and were in general use till 1837, when Pitman's phonography was published. About 100 works were issued on the subject in England between 1602 and 1830. In France, Conin de Perpeau's *Sténographie* and Grosselin's *Vocabulaire sténographique* were the most popular systems. The fundamental principle of these various systems, differ as they might in other respects, was that they represented, by the position of their characters, every letter of the alphabet, and the additional sounds of the double consonants *ch*, *sh*, *th*, &c., while phonography deals only with the actual sounds, and analyzes these, arranging them according to their mutual relations. The shorthand writers had also characters to represent prepositions and terminations, arbitrary signs to indicate words of frequent recurrence, and other methods of abbreviation, by omissions and the like.

STENTOR, a Grecian herald in the Trojan war. Homer describes him as "great-hearted, brazen-voiced Stentor, who was accustomed to shout as loud as 50 other men." Hence the name has been applied proverbially to loud-voiced persons.

STEPHANUS OF BYZANTIUM, the author of the geographical lexicon called *Εἰρηνα*, flourished probably in the beginning of the 6th century. There is scarcely another ancient author of whom so little is known, neither the age in which he lived nor any incidents of his life having been preserved; and his work, probably the earliest dictionary of geography ever written, exists only in an abridgment made by Hermolaus. A few fragments of the original are still extant. The title of the work has been made a subject of controversy. The original dictionary was full of valuable material for the history of ancient places and of quotations from ancient writers. There have been numerous editions of the epitome, of which the most useful is that of A. Westermann (8vo., Leipzig, 1839). It has been translated into German by S. C. Schirlitz.

STEPHEN, SAINT, the first martyr of the Christian church. He was, as appears from his name, a Hellenist by birth, and one of the 7 deacons in the Christian congregation of Jerusalem, who, upon the complaint of the Hellenists that their widows were neglected, had been chosen by order of the apostles to superintend every thing connected with the relief of the poor. The Jews charged him with having spoken against the law and the temple, against Moses, and against God, and by order of the sanhedrim he was stoned. Before his death he addressed his persecutors at length, and he died praying that those who put him to death might be forgiven. (Acts vi. and vii.) No information is given respecting the time of his death, but it is believed to have been in the year 36 or 37. He is annually commemorated by the Roman Catholic church on Dec. 26.

STEPHEN, the 4th king of England of the Anglo-Norman line, born in 1105, died Oct. 25, 1154. His father was Stephen, count of Blois, and his mother was Adela, or Adelia, the 4th or 5th daughter of William the Conqueror; and Stephen was their 8d son and 6th child. He early became a favorite of Henry I., his maternal uncle, who knighted him in his youth, and gave him the earldom of Mortagne in Normandy, beside bestowing upon him several valuable estates in England. He procured his marriage to Matilda, heiress to the count of Boulogne, as early as 1114, by which Stephen became possessed of that title and property. When, in 1120, William, the heir of Henry I., and so many other members of the king's family and household, were lost by the foundering of the White ship, Stephen was saved from the same fate by leaving the vessel in consequence of finding that she was too crowded for safety. Henry employed him in various ways, and

never abated his attachment to him, which originated in the circumstance that Adela, Stephen's mother, had been the king's most attached sister, rendering him important services when it was not supposed that he would ever reign. She had recommended her son, who was then a child, to her brother's protection, and Henry accepted and discharged the trust. Stephen was the second person of the laity who took the oath to support Henry's daughter, the empress, as queen of England and duchess of Normandy, should her father die without issue male. This oath was not thought to be binding, as it was not possible for a woman to discharge the duties of the kingly office according to feudal ideas of those duties, the most prominent regal attribute being command in war. The widowed empress, too, had married a Frenchman—Geoffrey Plantagenet, count of Anjou—and the marriage was in direct violation of the king's assurance, which was thought to have cancelled the obligation on the other side. It is asserted that Henry changed his mind just before his death, and released those who had sworn to support Matilda from their oath. Theobald, count of Blois, Stephen's eldest brother, was regarded by many Normans as the proper person to succeed Henry; but while they were deliberating, Stephen had hastened to England, and had there been crowned, Dec. 22, 1135. The archbishop of Canterbury believed that Henry had expressed an intention to leave his dominions to Stephen, whom the people loved because of his popular manners. He was, says Lappenberg, "distinguished for kindness, courtly manners, an amiable serenity of character, and a condescension which had long gained him the hearts of many among all conditions of people. On the other hand, he often proved himself imprudent and rash, and on his fairest promises no reliance could be placed. In short, he exhibited, in all its traits, a complete specimen of the accomplished Norman knight of those days, who, although capable of enacting many parts excellently well, was nevertheless but ill qualified to rule over a kingdom." Stephen confirmed to the English the immunities and good laws of Henry I., and also the laws and customs of Edward the Confessor. He obtained peace with Scotland by making cessions to King David, from whom he obtained acknowledgment and homage. At a meeting of barons and prelates at Oxford, he produced a letter from the pope expressing approval of his election to the throne. A charter was framed, by which the old privileges of all classes were confirmed, and certain abuses that had happened in the preceding reign were removed. The reign of Stephen was a period of constant war and tumult. He was involved in contests with the Welsh, who inflicted defeat and loss on the Normans. In the war that was renewed with Scotland in 1138, the English gained the great battle of the standard, Aug. 22. Revolts broke out, at different times, in various parts of the

country. The cause of the empress Matilda was early taken up by a party in England, headed by her natural brother Robert, earl of Gloucester; and on Sept. 30, 1139, Matilda landed in England. The war was waged with various fortune, but Stephen was defeated and made prisoner, Feb. 2, 1141, at the battle of Lincoln. The greater portion of the country submitted to the victors; but Matilda's arrogance was so offensive that a reaction speedily took place. Her brother was defeated and captured in Sept. 1141, and was exchanged for Stephen. At the battle of Wilton, July 1, 1143, Gloucester was victorious, and the king preserved his freedom only by flight. The war raged for years, and the condition of England was made most deplorable. In 1153 Henry, son of the empress Matilda, arrived in England at the head of a considerable force, and defeated Stephen at Malmesbury. He was about to prosecute his advantages, when the leading men on both sides interposed to bring about a peace. This was found a less difficult task than had been anticipated, in consequence of the sudden death of the king's eldest son, Eustace. By the treaty of Winchester, Nov. 7, 1153, it was settled that Stephen should remain king of England for life, and that he should be succeeded by Henry; and that Stephen's son William should retain all his possessions acquired by marriage or otherwise, and all those which his father had held in Normandy, England, and elsewhere, before he became king. Stephen did not survive the making of this treaty quite one year, dying after a brief illness. His reign was the most miserable time ever known in England. The country was covered with castles, many hundreds of which were erected at this period; and it was devastated by the foreign soldiery, the king himself employing numerous mercenaries, principally from Flanders and Brittany. Stephen was the last of the Anglo-Norman kings of England, the throne passing on his death to the house of Plantagenet, in the person of Henry II.

STEPHEN I., king of Hungary. See HUNGARY, vol. ix. p. 357.

STEPHEN, king of Poland. See POLAND, vol. xiii. p. 480.

STEPHEN, SIR JAMES, a British statesman and author, born in London in 1789, died in Coblenz, Sept. 15, 1859. He was graduated at Trinity hall, Cambridge, in 1812, and soon after called to the bar at Lincoln's Inn. He was appointed counsel in the colonial department of the public service, and in 1824 counsel to the board of trade. He held both offices until 1834, when he was promoted to be assistant under secretary. He was subsequently made permanent under secretary, and retired from office in 1847, when he was knighted. In 1849 he was elected regius professor of modern history in the university of Cambridge, an appointment which he held at the time of his death. For a number of years he was an active contributor to the "Edinburgh Review;"

and a collection of "Essays on Ecclesiastical Biography," first published in that periodical, has passed through several editions. He also published his collegiate course of "Lectures on the History of France" (2 vols., 1851), of which 8 editions have appeared, and some occasional lectures. A memoir of him is in preparation by his son Fitzjames Stephen.

STEPHENS, or STEPHANUS (Fr. *Estienne* or *Étienne*), the name of a French family of printers who flourished during the 16th and 17th centuries. HENRY, the founder of the family (born in Paris about 1460, died in 1520), established a printing house in Paris in 1502. He published mathematical and theological works, distinguished for the accuracy with which they were printed. His 8 sons, FRANÇOIS, ROBERT (born in Paris in 1503, died in Geneva in 1559), and CHARLES (born in Paris in 1504 or 1505, died in 1564), were largely engaged in printing. Robert, a man of great learning and industry, in his 20th year published an edition of the Latin New Testament, with some corrections by himself which excited the hostility of the doctors of the Sorbonne. At his house, which was the resort of the most eminent literary men of the day, Latin was the ordinary language of conversation, even among the children and servants, to whom it was taught by his wife, a woman of rare accomplishments. For many years scarcely a month passed in which some work, generally edited and corrected by himself, did not issue from his press. He is said to have publicly posted proof-sheets of his works, with the offer of a premium for the detection of errors. In 1531 he began the publication of his *Dictionarium, seu Thesaurus Lingua Latina*, which he successively improved in 2 subsequent editions. His editions of the Bible and notes brought him into trouble with the Sorbonne, from which however he was protected during the life of Francis I., who had appointed him royal printer. After the king's death the Sorbonne caused the sale of his Bibles to be prohibited, and to insure his safety the printer retired to Geneva, where he died, it is said, in the Calvinistic faith. He published at least 11 complete editions of the Bible, in Hebrew, Greek, Latin, and French, beside many separate editions of the New Testament; and 882 other works, mostly of the first importance, came from his press. He first introduced the existing division of the New Testament into verses. Charles, the younger brother of Robert, devoted himself to physical sciences, and for some years practised medicine. He succeeded to his brother's business when the latter retired to Geneva, and was subsequently appointed printer to Henry II. His publications, scientific and classical, are numerous.—HENRY, son of Robert (born in Paris in 1528, died in 1598), was esteemed one of the most learned men of his time. He spoke Latin with fluency while a child, and throughout his life was a profound student of Greek literature. His establishments were successively in Paris and Geneva;

but after the publication of his great work, the *Thesaurus Lingua Græca*, the costliness of which confined it to a limited number of purchasers and involved the printer in pecuniary embarrassments, he led a nomadic life, travelling from city to city, exploring libraries, and collecting an immense amount of material for works which he was projecting, and which he published wherever he happened to be.—Among others of the family were PAUL, son of the preceding (born in Geneva in 1566, died there in 1627), who succeeded his father in the management of the printing establishment at Geneva, which he conducted for many years; and ANTHONY his son (born in Geneva in 1592, died at the Hôtel Dieu in Paris in 1674), who for 50 years conducted a printing house in Paris with much energy, but died in great poverty.

STEPHENS, ALEXANDER H., an American statesman, born in Taliaferro co., Ga., Feb. 11, 1812. He was graduated at Franklin college, Athens, Ga., in 1832, studied law, was admitted to the bar in 1834, and rapidly obtained a large and lucrative practice at Crawfordsville. In 1836 he was elected a member of the lower house in the legislature of Georgia, was reelected for 5 successive terms, and exerted himself with success to secure legislative aid for the system of internal improvements. In 1839 he was a delegate to the commercial convention at Charleston, S. C., and defended the measures proposed by the Georgia delegates against the assaults of those from South Carolina; and in 1842 he was elected to the state senate, where he actively sustained the measures of the whig party. In 1843 he was elected to congress by over 3,000 majority, though his party had previously been in a minority of more than 2,000, and held his seat till 1859. He supported Mr. Clay for the presidency in 1844, though differing from him on the question of the annexation of Texas, in favor of which he made one of his earliest speeches during his first term in congress. The authorship of the resolutions for its annexation was indeed due to him, conjointly with the Hon. Milton Brown of Tennessee. In Feb. 1847, he submitted a series of resolutions in relation to the Mexican war, which afterward formed the platform of the whig party. He opposed the Clayton compromise in 1848, and took a leading part in effecting the adjustment known as the compromises of 1850. The passage of the Kansas and Nebraska act of 1854 in the house of representatives was in great measure due to his efforts, as chairman of the committee on territories. After the breaking up of the whig party Mr. Stephens united with the democrats, and was a prominent champion of the measures of Mr. Buchanan's administration. At the close of the 35th congress Mr. Stephens declined to be again a candidate. During the presidential canvass of 1860 he sustained Messrs. Douglas and Johnson, and in numerous public addresses denounced those who advocated a dissolution of the Union in case of Mr.

Lincoln's election, and in an address before the state convention called after that event vigorously opposed the secession of Georgia. On Feb. 9, 1861, he was nevertheless elected by the confederate congress at Montgomery, Ala., provisional vice-president of the confederate states, and was inaugurated on the 18th of the same month. On April 22 he made a speech at Richmond, Va., in justification of the secession movement, and in July visited the principal cities of the southern seaboard states to urge the taking of the cotton loan. In November he was elected permanent vice-president of the southern confederacy.

STEPHENS, ANN SOPHIA (WINTERBOTHAM), an American authoress, born in Derby, Conn., in 1813. She was married in 1832 to Edward Stephens of Plymouth, Mass., and in 1835 commenced her literary career as editress of the "Portland Magazine" and the "Portland Sketch Book," of which city her husband had become a resident. In 1837 she removed to New York, and soon became an active contributor to the "Ladies' Companion," "Graham's Magazine," and a variety of similar periodicals, in which occupation she has continued to the present time. Her most elaborate work, "Fashion and Famine" (New York, 1854), has had considerable popularity at home and abroad, having appeared in three French versions in Paris. Among her other works are "Mary Derwent," which gained a prize of \$400 offered by one of the periodicals; the "Heiress of Greenhurst," "The Old Homestead," and two books on needlework. She has been the editress of several literary magazines, for which she has written much in verse, but has published no collection of her poems.

STEPHENS, JOHN LLOYD, an American traveller and author, born in Shrewsbury, N. J., Nov. 28, 1805, died in New York, Oct. 10, 1852. He was graduated at Columbia college, New York, in 1822, studied law, and practised his profession in New York for 8 years. He then spent two years in foreign travel, and in 1837 published his "Incidents of Travel in Egypt, Arabia Petrea, and the Holy Land," followed in the succeeding year by "Incidents of Travel in Greece, Turkey, Russia, and Poland," both in 2 vols. 12mo. The lively style and great descriptive power of these works procured them a very large circulation both in America and Europe. In 1839 he was appointed by President Van Buren special ambassador to Central America, explored the ancient remains of that country, and on his return published "Incidents of Travel in Central America, Chiapas, and Yucatan" (2 vols. 8vo., New York, 1841); and in 1842 he again visited Yucatan, and published "Incidents of Travel in Yucatan" (3 vols. 8vo., 1843). These works were illustrated by his fellow-traveller, Mr. Oatherwood, and the last two named are of special value as contributions to American antiquities. In 1846 Mr. Stephens was elected a member of the convention for revising the constitution of

the state of New York. He was a director of the "Ocean Steam Navigation Company," which established the first American line of transatlantic steamships, and went to Europe as the representative of the company on the trial trip of its first vessel, the Washington. In 1849 he was elected vice-president of the Panama railroad company, negotiated the contract for the right of way with the government of New Granada, was chosen president of the company, and during the winter of 1851-'2 personally superintended the construction of the road, which was nearly completed before his death.

STEPHENSON, a N. W. co. of Illinois, bordering on Wisconsin, and intersected by the Pecatonica river; area, 550 sq. m.; pop. in 1850, 11,666; in 1860, 25,118. The surface is undulating and the soil fertile. The productions in 1850 were 228,267 bushels of wheat, 802,285 of Indian corn, 227,310 of oats, 16,023 tons of hay, 288,567 lbs. of butter, and 18,404 of wool. There were 8 newspaper offices, and 1,800 pupils attending public schools. Lead is found. It is traversed by the Illinois central and the Galena and Chicago railroads. Capital, Freeport.

STEPHENSON, GEORGE, the founder of the railway system of Great Britain, and perfecter of the locomotive engine, born in Wylam, Northumberland, June 9, 1781, died at Tapton park, near Chesterfield, Derbyshire, Aug. 12, 1848. His father, a worthy and industrious man, was fireman of the pumping engine at Wylam colliery, and by his utmost exertions was barely able to provide food and clothing for his family, much less to send them to school. George, the 2d of 6 children, consequently grew up without the slightest knowledge of books, and at 9 years of age was employed at two pence a day to look after the cows of a neighbor, to which succeeded other kinds of farm work. It was, however, his highest ambition to follow his father's occupation; and at the age of 14, being known as a steady, intelligent boy, with a taste for mechanics evinced in the construction of miniature engines and windmills, he was appointed assistant fireman at the Dewley Burn colliery, whither the family had removed. For several years he continued to be employed at various collieries as fireman, and afterward as plugman, and gradually acquired so complete a knowledge of the engine as to be able to take it apart and make any ordinary repairs. At 18 he was still ignorant of reading, and even of the letters of the alphabet; but within two years, partly by attending small night schools resorted to by the colliers' children, partly by his own perseverance, he was able to read, write, and cipher with tolerable facility. In 1802 he was married, but became a widower within two years, and removed in 1805 with his infant son, Robert, to Killingworth colliery, where his little earnings were speedily absorbed by the demands which his father's poverty imposed upon

him, and by the payment of a considerable sum to procure a substitute in the militia, for which he had been drawn. At this time he was desirous of emigrating to the United States; but being unable to raise sufficient money to pay for his passage and outfit, he set himself steadily to work to repair his losses. In his leisure hours he studied mechanics and engineering, mended clocks and shoes, cut out clothes for the miners, and turned his hand to so many useful purposes that he was regarded by his fellow laborers in the colliery as a sort of universal genius. What was of more benefit to him was the favorable impression which his suggestions for improvements in machinery made upon his employers, who in 1812 appointed him engine-wright at Killingworth, at a salary of £100 a year. With this event his mechanical genius seemed to take a fresh start, and beside erecting a winding engine for drawing up coal and a pumping engine, he projected and laid down a self-acting incline along the declivity of the Willington ballast quay, so arranged that full wagons descending to the vessels drew up the empty ones. The construction of an efficient and economical locomotive steam engine, however, occupied his attention beyond any other subject; and after a careful examination of all the machines within his reach, he commenced, and in July, 1814, completed an engine, which worked successfully on the Killingworth railway, and proved the best yet constructed, though its operation was by no means satisfactory to the inventor. It was the first locomotive made with smooth wheels, and from the outset he rejected the clumsy contrivances which Trevethick, Blenkinsop, and others had thought necessary to secure sufficient adhesion between the wheels and the smooth iron surface of the rails to allow the propulsion of a train. At this early day also he told his friends "there was no limit to the speed of such an engine, if the works could be made to stand it;" an opinion he was subsequently obliged to maintain almost single-handed against the most experienced engineers of England. While engaged in plans for an improved engine, his attention was attracted to the increase in the draught of the furnace obtained by turning the waste steam up the chimney—a practice originating solely in the desire to lessen the noise caused by the escape of the steam; and it immediately occurred to him that the proper application of this principle, by increasing the force of the fire, would greatly augment the power of the boiler to generate steam, and the range and capacity of the engine. Hence originated the steam blast, the most important improvement in the locomotive made up to that time, which, however, has also been claimed for Hackworth, another inventor. It was embodied in Stephenson's next engine, completed in 1815; and in 1816 he constructed others, greatly simplified in the working parts, and which as recently as 1854 formed the model for those employed at

Killingworth to drag coal. About this period he invented a miner's safety lamp to obviate the frequent explosions from fire damp, one of which had occurred in 1814 in the colliery under his care. The subject was at the same time brought under the notice of Sir Humphry Davy, and both he and Stephenson, though living hundreds of miles apart, and personally unknown to each other, constructed lamps founded upon identical principles, but arrived at independently by different trains of thought, the former working out his ideas scientifically, the latter mechanically. Stephenson's lamp was practically tested by himself at Killingworth in Oct. 1815, nearly 3 weeks before Sir Humphry made public his invention, and is still employed there. To Davy nevertheless was ascribed the priority of invention, and a sum of £2,000 was raised at a meeting of coal miners and presented to him, £100 being at the same time assigned to Stephenson. The friends of the latter, deeming that injustice had been done him, soon after presented him with £1,000, a proceeding warmly criticized by Sir Humphry, and which provoked a bitter controversy between the partisans of the rival claimants. Having brought the locomotive to a considerable degree of perfection, Stephenson next turned his attention to the improvement of railways, his opinion being that both were parts of one mechanism, and that the employment of steam carriages on common roads was impracticable. For the purpose of making his railways solid and level, and to prevent jerks at the junction of the rails, he took out in 1816 a patent for an improved rail and chair, recommended the employment of heavier rails and the substitution of wrought for cast iron, and established the gauge still generally in use. In connection with these improvements he added considerably to the lightness and strength of the locomotive, and substituted steel springs for the small cylinders on which the boiler had at first rested. Soon after the general peace of 1815 the necessities of internal commerce began to suggest the establishment of railways, although the employment of steam power, except for the purpose of expediting the ascent of heavy grades, was generally considered impracticable. Stephenson and a few others, however, ventured to believe that the locomotive was destined to supersede the mail coach, and the railroad to "become the great highway for the king and all his subjects." His first important undertaking was the construction of a railroad 8 miles in length for the owners of the Hetton colliery, which, on Nov. 18, 1822, was successfully opened, the level parts being traversed by locomotives, while stationary engines were employed to overcome the heavy grades. While this work was in progress similar projects began to be agitated, and in 1820 an act of parliament was obtained for a railway between Stockton and Darlington, of which Stephenson was appointed engineer at a salary of £300. The line was intended to be worked by station-

ary engines for the steep gradients, with horse power on the level portions; but at Stephenson's urgent request the act was amended so as to permit the use of locomotives on all parts of the road, which, at the expiration of somewhat more than 3 years from its commencement, was formally opened on Sept. 25, 1825, in the presence of immense throngs of spectators. The difficulty experienced in procuring suitable locomotives from the ordinary blacksmiths' shops suggested to him the necessity of establishing a special engine factory, which project was successfully carried into effect, with the coöperation of Mr. Pease, the originator of the Stockton road, at Newcastle-upon-Tyne, where some of the most powerful steam carriages in the world have since been constructed, and many skilled workmen and engineers educated. The year 1825 witnessed the production of a multitude of projects for railways, of which the Liverpool and Manchester line, the most considerable and the only one seriously supported, was destined to be not merely the great achievement of Stephenson's career, but the battle field on which were to be fought the momentous questions of the superiority of railways to common roads, of high to low velocities of transport, and of locomotives to fixed engines. Stephenson made the preliminary surveys in the teeth of an opposition which might have readily disconcerted a less determined spirit; and such were the ignorance and prejudice of land owners and their agents, who sometimes drove the surveyors off their grounds, that much of the work had to be done by stealth. An act of parliament having been procured, Stephenson was appointed principal engineer, and in June, 1826, commenced the construction of the road, which employed him incessantly during the next 4 years. Of the engineering difficulties successfully overcome, the most important was the crossing of Chatmoss, a bog $4\frac{1}{2}$ miles in length, pronounced impassable, on which the road was made to float; a feat, as has been observed, "affording an unequivocal proof of that admirable self-reliance which never contemplates failure." The patience of Stephenson was however destined to be still more severely tried: for during the progress of the undertaking the most eminent engineers persisted in recommending stationary engines in place of locomotives, which they declared unsafe and incapable of attaining a high degree of speed; and the clumsy expedient of a series of stationary machines $1\frac{1}{2}$ miles apart, dragging the trains by ropes, was seriously entertained, and would have been adopted but for the energy of Stephenson and a few of his friends. He finally prevailed on the directors to offer a prize, under certain stipulations, for the most effective locomotive engine for the purposes of the road; and at a trial which took place near Liverpool, Oct. 6, 1829, his engine, the "Rocket," constructed by himself and his son Robert, was adjudged to be the best of the 4

entered, having averaged a speed of 14 miles an hour, and even attained a velocity of 29 miles an hour. The "Rocket," the first high-speed locomotive of the standard modern type, was distinguished above all preceding ones by 3 elements of efficiency: the multitubular boiler, which, if not Stephenson's invention, was first applied by him to locomotives; the blast pipe; and the direct connection of the steam cylinders to one axle and one pair of wheels. At the ceremony of the opening of the road, Sept. 15, 1830, Mr. Huskisson, who was in attendance with many other distinguished public men, having been accidentally struck down and fatally injured by this engine, was conveyed in it from Parkside to Eccles, a distance of 15 miles, at the then unprecedented rate of 36 miles an hour. Having fairly inaugurated the railway system of England, Stephenson was almost incessantly employed for the next 10 years on new roads which were projected in all directions, and even visited Belgium and Spain as a consulting engineer. With his increasing wealth he also engaged extensively and profitably in coal mining, particularly in the neighborhood of Tipton park, an elegant seat in Derbyshire, where he passed his latter years in comfort and peace, beloved by his neighbors of every degree and condition, and presenting in his conduct, as well as in his person and manners, the true ideal of an English gentleman. He preserved through life the simplicity of character which had distinguished him in youth, and on several occasions declined the honor of knighthood. Of his scientific character, Sir J. D. Forbes, who disclaims for him any great inventiveness, makes the following estimate: "His skill rather lay in perceiving how far methods and contrivances already known might be pushed to an advantageous result. He possessed that shrewd decision which ingenious persons often want, enabling him to detect what is truly valuable in the numerous mechanical schemes which at any time are afloat, and to devise the means of realizing them. He also possessed that confidence in his own judgment which is necessary to carry out principles to their legitimate extent, but from which feebler or more practical minds usually shrink." A memoir of George Stephenson, by Samuel Smiles, was published in London in 1856.—ROBERT, a railway constructor and engineer, son of the preceding, born in Willington, near Newcastle-upon-Tyne, Dec. 16, 1803, died Oct. 12, 1859. As a child he evinced remarkable intelligence, and became in some sort a fellow pupil in several branches of knowledge with his father, whose own education was continued far into middle life, and whose earnings were long devoted exclusively to the instruction of his son. The latter, who at 12 years of age began to show a decided inclination for mechanics and science, was, after several years' schooling at Newcastle, and a preparatory training in the collieries, sent in 1822 to the university of Edinburgh.

He returned home in the succeeding year, and after assisting his father in a variety of undertakings and perfecting his knowledge of practical mechanics, accepted in 1824, in the hope of benefiting his health, an engagement as mining engineer in South America. Recalled by his father in 1827, he was employed in various labors connected with the construction of the Liverpool and Manchester railway, and in the improvement of locomotives; and in 1829 he assisted in designing and making the successful locomotive, the "Rocket," which was entered in his name. After being engaged on several minor railway lines, he was appointed engineer of the London and Birmingham road, which under his direction was completed in 1838; and thenceforth for many years his time and talents were almost exclusively occupied with similar undertakings at home and abroad. As an engineer he is known by several stupendous works designed in immediate connection with railways, among the most remarkable of which are the high level bridge over the Tyne at Newcastle, the viaduct over the Tweed valley at Berwick, the Conway bridge, and above all the Britannia tubular bridge across the Menai straits, 1,850 feet in length and 106 above high water mark, which Sir James Forbes pronounces "a triumph of art and science, an honor to his own age, and a lesson to posterity." In this last undertaking he received important assistance from Messrs. Hodgkinson and Fairbairn with respect to various points of construction and the strength of materials; but the credit of conceiving the enterprise belongs wholly to himself, as well as the rectangular form of the tube, of which there had previously been no example in mechanical construction. He was also employed on railways in Belgium, Norway, Italy, France, and other parts of Europe, and visited Egypt several times to superintend the construction of a road between Alexandria and Cairo, on the line of which there are two tubular bridges, traversed by trains on the roof instead of the inside, as in the case of the Britannia bridge. He also designed an immense bridge across the Nile at Kaffre Azzayat. In British North America he has left a memorable specimen of his engineering skill and perseverance amid unprecedented difficulties in the great Victoria tubular bridge, which crosses the St. Lawrence near Montreal, and was formally opened by the prince of Wales in the summer of 1860. In addition to his railway labors he took considerable interest in public affairs, and during the last 12 years of his life represented the Yorkshire borough of Whitby in parliament, where he was known as an able debater on subjects connected with the railway interests of the United Kingdom. He was also a member of several scientific bodies, and received a great gold medal of honor from the French industrial exposition of 1855. His great wealth was liberally expended, and he enjoyed a reputation for private worth and mechanical ge-

ninus not less distinguished than that of his father. He published a work "On the Locomotive Steam Engine," and another "On the Atmospheric Railway System."

STEPPE. See PLAINS.

STEREOSCOPE (Gr. *στερεος*, solid, and *σκοπεω*, to see), an optical instrument contrived for combining into one image, which appears solid, or in relief, two plane representations of a statue, a landscape, or any object or field of objects involving three dimensions. The two separate pictures employed for this purpose are so taken as to show the object or field as it would appear when viewed by each of the two eyes separately. Of such pictures, now known as stereoscopic views, the effect, and hence the preparation, depend on the two simple principles, that within certain limits of distance the two eyes see at the same time two really unlike pictures of any solid object or field of objects regarded; and that when two such pictures (for present purposes considered as flat) fall on the retinae of the corresponding eyes, the result is a perception of solidity in the objects, or of depth in the field, so presented. If a thin book be held up before the eyes, with the back toward the face, and looked at with the right eye only, the back and much of the corresponding side are seen, and in a certain direction; but on looking with the left eye only, the image of the book and the plane in which it appears to lie shift slightly toward the closed eye, and the back with the other side now becomes visible. The book presents to each eye a somewhat different surface, and a different position and perspective. On carefully regarding it with both eyes, its apparent position is intermediate to the two before found; the back and in a degree both the sides are now visible, and the book obviously stands in relief toward the eyes. These appearances, alluded to by Euclid, were more definitely observed and described by Galen about 1,700 years since. The familiar but remarkable result is, that we neither see objects double nor as flat surfaces; but always, when not too far removed, as having depth or relief, or as existing in a space which shows this third dimension. (See VISION.) A diagram expressing to the eye Galen's results was drawn by Baptista Porta; and from this, about A. D. 1593, Jacopo Chimenti prepared pairs of drawings (one pair of which is believed to be still preserved in a museum at Lille) intended to show persons as seen by the two eyes separately, and such that, if viewed with the eyes "crossed" by looking at a point nearer to them than are the drawings, so that each eye receives the image of that which is before the other, they are combined, giving a single image in relief. This method, the "ocular stereoscope," is still conveniently resorted to, after some practice, by those who would get the stereoscopic effect of views without employing an instrument. Aquilonius (1613) wrote a volume on the vision of solid objects,

in which this principle was introduced. Mr. Harris (1775) treated on the subject, among other things referring the obviously solid form of the nose as seen by its owner to this effect of vision with two eyes. Prof. Elliott, in 1884, is said to have conceived the plan of an instrument for combining the two single-eye pictures, mentioning it to two or three friends, but not carrying it into execution until 1889. Meanwhile, however, Prof. Wheatstone—to whom is unquestionably due the credit of having devised the first effectual and satisfactory instrument for combining two monocular drawings or pictures into a solid image, as well as of having distinctly brought before the physicists and the public the truth that our actual perception of solidity depends on the combination of two such visual pictures—had exhibited before the royal society in 1838, and also at a meeting of the British association, his “reflecting stereoscope,” demonstrating its power to unite pairs of plane geometrical drawings into single and solid forms. Elliott’s device was simply a wooden box, 18 inches long, 7 broad, and $4\frac{1}{2}$ deep, in the closed or remote end of which the dissimilar pictures were placed. The views he first employed were two representing a leaning cross, with the moon and the branchless stem of a small tree, nearly in line, and as seen from slightly different positions. No mirrors or lenses are required; but on looking into the box, on the “ocular stereoscope” plan, crossing the eyes, the entire view appears to stand forth in solidity or relief. Wheatstone’s arrangement, far superior to this, consists of two plane mirrors about 4 inches square, so placed as to make each an angle of about 45° with the axis of the corresponding eye, the two mirrors being thus at right angles to each other, and the drawings on separate slips being presented, each toward a mirror, at the two sides, and at such a distance and angle that the reflected images thrown to the two eyes respectively shall appear to have come from a single object at a corresponding distance behind the mirrors. Thus the two views are in effect superimposed and united, as in natural vision; and if unlike each other in quite or nearly the same way as when received by the eyes from the actual object, the latter will be exactly represented, though it may be on a reduced scale, but appearing in solid form, so that we seem even to look around and beyond it. Two pictures of a bust become in effect a solid bust; the waters of a cataract stand forth in body; a forest, a mountain, or a group of persons comes out in depth, and we look between and beyond the individual objects, as in the natural view. In 1849 Sir David Brewster devised a more convenient form of instrument for combining the two pictures, which is now in common use. In this, two convex lenses properly adjusted are employed for viewing the pictures; or more commonly, parts of a single large double-convex lens, divided in the middle, the thin edges being set

toward each other, and at the ordinary distance of the two eyes, about $2\frac{1}{2}$ inches apart. These are placed in a convenient box, into which the observer looks; while beyond them are the slides or double views, which, in case they are opaque, as upon pasteboard, are viewed by reflected, or if transparent, as on glass, by transmitted light. A diaphragm, extending from in front between and to a little way beyond the two semi-lenses, confines the vision of each eye to its appropriate picture; while the lenses, refracting laterally outward to the eyes the light which passes through them, cause the two images to appear as if originating from a single field between the real places of the views, that is, they superimpose these; and at the same time their effect is to magnify the single resulting image. The instrument is known as the “lenticular stereoscope.” In the best simple or hand instruments, the semi-lenses being cut from a single lens not less than 3 inches in diameter, and set edge to edge, a single wide aperture serves for both eyes; and the instrument then suits all eyes without adjustment, and allows of an increased field of view.—As no artist can continually and with certainty execute true pictures of trees, persons, or other near objects, with just those differences of surface and perspective which they naturally present to the two eyes separately, it will readily be seen that the stereoscope could be of little use until aided by photography. The pictures employed must be correct, or their faults are exaggerated. Public attention seems first to have been strongly called to the stereoscope as a means of amusement and of the improved representation of objects, by the fine display of lenticular stereoscopes and of appropriate photographic views placed by M. Duboscq in the great exhibition at London in 1861.—It is certain that the perception of solidity or relief, in ordinary vision, is in some way connected with the degree of convergence of the axes of the two eyes (the optic axes) toward the object, or the point on its surface of which at any moment distinct vision is secured. Though we usually judge of distances in a considerable degree, and beyond a certain limit wholly, by light and shade, or aerial perspective, by intervening objects, and by aid of experience, yet when the objects or their parts are within about 250 to 300 feet, there is a sensible difference in the degree of convergency of the optic axes, and hence in the effort to fix the eyeballs in the required positions, and doubtless therefore in the attending muscular sensations. Within some limit, probably that named, the degree and character of these sensations, though unconsciously to him, enable the observer to judge of distances; to determine that some parts of a given object are nearer, others more remote; and thus, perhaps, during the rapid play of the eyes over the object, to obtain that sense of distances which we interpret into solidity of the object. For objects about 250 feet away, the optic an-

gle is small, and the sensation of effort slight; for those much beyond this, both these in effect vanish, and relief is no longer a perception, but only an inference; for distances far within the limit, the convergency and sensation become marked. Looking into the stereoscope, the effort to converge the eyes must be made, the sensation of such effort attends, and relief is perceived. It may be in this way that two views of an object a mile distant, and taken by the double camera in common use, its lenses little further apart than the eyes, still show relief when seen in the instrument; and that, as has been stated, even two flat pictures exactly alike have in the instrument been made to afford a view in relief. Brewster argues that to produce perfect stereoscopic effect, the two views should always be taken through lenses of the double photographic camera, having no more than $\frac{1}{4}$ inch diameter, and placed no more than $2\frac{1}{2}$ inches apart, or successively through one such lens shifted only to such distance, so as to answer exactly to the pictures furnished in nature to the two eyes. When there are moving objects in the field, and also in taking "instantaneous views," so called, the double camera becomes requisite, or two single cameras, stationed at suitable distance and acting together. For stationary objects the single camera is conveniently used, the pictures being taken in succession. In taking stereoscopic pictures, it has been customary (though probably the tendency is now back toward the natural conditions) to exaggerate the effect both in respect to distance between stations and to the size of lens. When the plates used are less sensitive, larger lenses may be employed to accelerate the process; sometimes those of 2, 3, or 4 inches diameter. So a broad base or distance between stations of the camera is resorted to for the purpose of exaggerating the relief; for near persons or statues, sometimes as much as 6 to 8 inches; for landscapes, 10 to 20 inches, or even several feet. Thus, strongly differing sides, perspectives, or projections of the objects are obtained. In the double camera, the tubes through which light enters, to be thrown by a convex lens in each on the prepared plates, are not parallel, but inclined to each other at a certain angle, which is usually less in the cameras for taking portraits than in those for views. But in taking the photographic visiting cards, by 4 parallel tubes directed toward the person and view at the same time, 4 pictures are obtained; then, without shifting the person or instrument, 4 others upon another portion of the same slide; and it is unexpectedly found that of these, any right-hand image being suitably placed in the stereoscope with any left-hand image, perfect relief is the result. With near objects, a long base line and marked difference of perspective result in distorting the objects in the direction from before backward (that of depth); all streets, buildings, and similar views extending away from the eye, appear disproportionately long; and in

persons, the head, or an advanced foot, or the dress, is thrown forward to a disagreeable extent. This principle, however, becomes useful in case of bodies so distant that to the eyes, near together as they are, they cannot present the solid form. Remote mountains, buildings, &c., flat to ordinary vision, are made to give unlike views by placing the cameras many feet apart, as they would to a person whose visual organs could be correspondingly separated; and in the stereoscope such views actually give the solid form. This is also the principle of the tele-stereoscope of Helmholtz, in which 4 mirrors are so placed diagonally, the outer pair many feet apart, and the inner at the distance suiting the eyes, that the binocular parallax or angle between the two lines of sight is greatly enlarged, and distinct relief is secured in objects very remote. The angle made by the axes of the two eyes at the point viewed (the "optic angle") is, by both the two methods last named, in effect greatly enlarged—this angle being always a horizontal one—as if the object were very near; but the visual angle of the object, usually regarded especially in the vertical direction, remaining just what it would be with the ordinary base between the eyes, the result is that the judgment of the observer is deceived, and, unless proportionate magnifying power of lenses be employed, the object appears actually diminished in size. The principle of increased distance between stations is availed of in taking stereoscopes of the moon, as has been done by L. M. Rutherford of New York, and by W. De la Rue of London. At different seasons the moon presents slightly different faces toward the earth; and two views taken from positions in the earth's orbit 15° apart, and placed in the stereoscope, give a perfect and beautiful globe, its surface diversified with the well known lights and shades of that luminary. M. Olandet, of London, has devised a method in which relief is secured by means of the image of a single picture or object thrown on a ground glass screen, hence termed a stereomonoscope. In this case it is asserted that the image in relief is visible to several spectators at the same time. Another method, by Mr. Maugham, applies glasses of complementary colors, say green and red, to the rays which are thrown by a magic lantern on the screen, and corresponding glasses to the two eyes of each observer, in order to keep separate the rays of the two images; but much light is in this way lost, and the image is faint. Mr. Thomas Skaife, of Blackheath, England, using a small thin lens, of 1 inch focus, has obtained almost instantaneous views which, when magnified, are still extremely well defined and perfect, and which he has termed pistolographs. Enclosed between two plates of glass, and the three semi-fused into one, one of these miniature pictures retains its beauty, while it is protected and preserved; the combination he has termed the chromo-crystal. It is stated that Mr. John Sang, of Kirkcaldy, has recently, by

means as yet kept secret, imparted the stereoscopic effect, or relief, to copies of flat surfaces, such as paintings and engravings.—Several instruments have been invented for the purpose of exhibiting a large number of views in succession, usually involving the revolution of an endless band carrying holders, in which the slides or views are previously placed, and by which they are brought successively into suitable position. Prof. H. W. Dove, by covering slides with printed lines, each one repeated, for one eye commencing evenly, and for the other every alternate line being set in or indented, has secured a perfect imitation of the effect of a double-refracting crystal. He has accordingly proposed to detect spurious bank notes which are copies of the genuine, by observing any suspected note alongside of one known to be genuine in the stereoscope; if the former be spurious, slight misplacements of words or lines, inappreciable to the unaided eye, will distinctly show the double-refractive effect, by an apparent projection of such out of the plane of the paper. Copies of prints or drawings may in like manner be known from the originals; with genuine duplicate notes or prints the effect is not observed. Other applications have been proposed, though not yet probably to any great extent adopted. But as a means of amusement, within the past 10 years the stereoscope has risen to a very prominent place in commerce as well as in art; and experienced artists are already visiting almost every portion of the earth's surface, known or supposed to offer objects of historical interest or scenery of striking character; while groups illustrative of domestic and other supposable scenes and situations are multiplied continually.—Prof. E. Emerson, of Troy university, N. Y., has devised a simple means of remedying a common defect of the lenticular stereoscope. (See the "American Journal of Science," Nov. 1861.) The two semi-lenses being fixed at the distance from each other supposed to be that ordinarily required, there may still be very great difficulty or even an impossibility of uniting the two pictures on the slides into one impression in relief; and this mainly from two causes—that the pictures are at improper distances apart, the distance between their centres varying from $2\frac{1}{4}$ to $3\frac{1}{4}$ inches; and that the width between the observer's eyes may also change much. An instrument enabling us to see equally well views whose separation may vary by an inch or more thus becomes a desideratum. In the ordinary arrangement, moreover, the size of each picture is confined to about 3 inches each way, or an area of 9 square inches; the views must be taken under an angle correspondingly small; and even if these be afterward magnified in viewing, still nothing is added in this way to the actual completeness of details. Now, while the lenses employed in the stereoscope are each constant in focal length, yet each will vary in the power of de-

flecting a ray, this power increasing from the centre out to the thin edge. Consequently, pictures at such distance apart as to be readily united through the middle part of the lenses, require to be separated more and more as we separate the lenses themselves, looking through their more deflecting portions. This circumstance suggests the means of giving to the instrument a general character, and adapting it to all sorts of views as well as to differences in the width between the eyes. The modification given is that of rendering the lenses movable in a horizontal direction, approaching till the edges touch, or separating as far as the eyes will allow, each lens moving through slightly more than an inch. The lenses must move simultaneously, at the same rate, and in opposite directions; when the right lens moves to the right, the left goes to the left, and *vice versa*. This is accomplished by fitting the lenses to slide in a brass frame, and attaching the lower edge of each to a nut; within the right nut turns a right-hand screw, and within the left a left-hand screw; and the threads of both screws being cut in the same horizontal rod, both lenses are actuated simultaneously and oppositely by turning the rod by a milled head at one side of the instrument. With this arrangement, the separation of the centres may vary from 2 as far as to $4\frac{1}{4}$ inches, or with achromatic lenses to 5 inches; and as an incidental advantage, views may thus be employed which, as taken, cover an area of 20 square inches, or twice that of those in general use.

STERLING. See POUND STERLING.

STERLING, JOHN, a British author, born at Kaimes castle, in the isle of Bute, July 20, 1806, died at Ventnor, in the isle of Wight, Sept. 18, 1844. His father, Edward Sterling, had been educated for the Irish bar, had served for a time as captain in the army, was now occupied as a gentleman farmer, and afterward became a leading writer of the London "Times." John was the second of 7 children, 5 of whom died in youth. The family removed to Paris during the peace of 1814, but fled on the return of Napoleon from Elba, and settled in London. At the age of 16 he was sent to the university of Glasgow, whence he was removed in the following year to Trinity college, Cambridge, where he was the chief speaker in the union debating club, and was intimate with a group of young men including F. D. Maurice, R. O. Trench, J. M. Kemble, Charles Buller, and Monckton Milnes. In 1828 he and his friend Maurice became proprietors and editors of the recently established "Athenæum," which soon passed out of their hands. Sterling continued to reside in London, and gained the friendship of Coleridge, of whom he was a most enthusiastic admirer. In 1829-'30 he wrote his novel of "Arthur Coningsby" (3 vols., 1838), the hero of which foreshadowed his own career by passing through radicalism, by means of what Car-

lyle calls the "Coleridgean legerdemain," up to faith in the church, in which he finally takes orders. In 1830 he was married, and soon after, for the benefit of his health, went with his wife to the island of St. Vincent in the West Indies, where he resided 15 months on a sugar estate. In 1833, under the influence of his former tutor, J. C. Hare, and of Coleridge, he resolved to enter holy orders, was ordained deacon at Chichester in 1834, and at once became curate of Hurstmonceaux in Sussex, where his friend Hare was rector. At the end of 8 months ill health compelled him to retire from the ministry, which he never resumed. He removed to London, where he now first met Carlyle, who soon filled the place of Mentor to him, which had before been held by Coleridge. From this time literature was his chief pursuit. Carlyle describes him as busy but unproductive, roaming among his friends, a welcome illumination to all, his address everywhere pleasant and enlivening. His ill health continuing, in 1836 he went to the south of France, and in the following year to Madeira; part of the years 1838 and 1839 he passed in Italy; visited Madeira again in 1840; and in 1841 settled at Falmouth, from which he made frequent visits to London. Meantime he had contributed to "Blackwood's Magazine" his delightful "Legendary Lore;" wrote for the "Westminster Review," then under the charge of John Stuart Mill; and was engaged on other compositions, in prose and verse. For the purpose of meeting him on his hasty visits to London, the Sterling club had been formed, among the members of which, beside his friends already mentioned, were Tennyson and Sir G. C. Lewis. He published in 1839 a collection of minor poems; in 1841 "The Election," a poem of English life and society; and in 1843 a drama entitled "Strafford." During the last named year both his wife and mother died, and his own health was rendered more precarious by the bursting of a blood vessel. He retired in 1843 to the isle of Wight, and there commenced a poem entitled "Oœur de Lion," which he did not live to complete. In 1848 a collection of his "Essays and Tales," from periodicals, was edited by Archdeacon Hare, with a biography prefixed (2 vols.). The biography dwelt specially upon the religious aspects of his character, as a heroic truth-seeker and a laborious curate. Mr. Carlyle, deeming this the least significant phase of his career, holding that artistic admiration was his *forte*, and not devotion in any form, and condemning his entrance into the church as "a weak, false, unwise, and unpermitted step," published in 1851 his own "Life of Sterling," one of his best productions and one of the most remarkable of biographies. In 1851 "Twelve Letters by John Sterling" were edited by his relative, Mr. Coningham.

STERNBERG, ALEXANDER VON, baron, a German novelist, born near Revel, in Esthonia, April 22, 1806. He was educated at Dorpat,

and abandoned the study of law for literature. He left Russia in 1830, passed several years in travel, and since 1843 has lived in Berlin. His writings are lively, satirical, and aristocratic. Several collections of his works have been published.

STERNE, LAURENCE, an English divine and author, born in Clonmel, Ireland, Nov. 24, 1713, died in London, March 18, 1768. His parents were both English, and his father, Roger Sterne, a grandson of Dr. Richard Sterne, archbishop of York in the time of Charles II., was a lieutenant in Handaside's regiment, the movements of which, "from barrack to transport, from Ireland to England," young Laurence followed until his 10th year, when he was put to school at Halifax in England. Having been adopted by his kinsman, Mr. Sterne of Elvington, he was in 1733 admitted of Jesus college, Cambridge, where he was graduated in 1736; soon after which he took orders and was presented, through the influence of his uncle, the Rev. Jaques Sterne, to the living of Sutton in Yorkshire, to which preferment a few years later was added a prebend in York cathedral. In 1741 he was married after an ardent courtship of several years, although he lived long enough to cordially hate his wife; and about the same time, through her connections, he obtained the living of Stillington, adjoining Sutton. For nearly 20 years he pursued the career of a rural incumbent, enjoying good health and amusing himself with "books, painting, fiddling, and shooting;" and during this period his only publications appear to have been two sermons, although he probably wrote political paragraphs for the newspapers, and is said to have conducted for some time a periodical electioneering paper in the whig interest. In 1759 he published at York, under the pseudonym of "Mr. Yorick," the first two volumes of "Tristram Shandy," which were reprinted in London early in 1760. The 3d and 4th volumes appeared in 1761, the 5th and 6th in 1762, the 7th and 8th in 1765, and the 9th in 1767. Long before the completion of the work, the charm and the novelty of the style, abrupt and exclamatory rather than continuous, the whimsical digressions, the exquisite touches of pathos and humor, and its many admirably conceived characters, had taken an extraordinary hold upon the public, and Sterne took his place by the side of Fielding and Richardson and Smollett as a great writer of prose fiction. He was extensively lionized in London, where people were invited a fortnight in advance to dine with him; and Boswell has recorded Johnson's remark that "the man, Sterne, had engagements for three months." The erudition which so greatly astonished the not very learned readers who welcomed the appearance of "Tristram Shandy," will however scarcely stand the test of modern criticism; and it has been shown by Dr. Ferriar in his "Illustrations of Sterne" (1798), that the quaint imagery and the quainter conceits and fancies scattered through

the book, were largely borrowed from Rabelais, Burton, and other authors not generally read in Sterne's time or even now. But after making liberal allowances for plagiarisms, his *Uncle Toby*, *Corporal Trim*, *Mr. Shandy*, *Dr. Slop*, and *Widow Wadman*, "creations of a fine fancy working in an ideal atmosphere, and not mere copies or caricatures of individualities actually observed," must be considered beyond all doubt among the most original personages in fiction; and in his peculiar vein of humor it would be difficult to name any author whom he resembles. Thackeray has noted the influence of Sterne's early association with military men and scenes upon some of the most delightful and picturesque passages, which he characterizes as "reminiscences of the boy who had lived with the followers of William and Marlborough, and had beat time with his little feet to the pipers of Ramillies in Dublin barrack yard, or played with the torn flags and halberds of Malplaquet on the parade ground at Clonmel." In 1760 and 1766, during the publication of "Tristram Shandy," appeared 4 volumes of sermons, also by "Mr. Yorick," which met with considerable favor, more perhaps on the score of their paternity than on account of their actual merit. Gray, in his correspondence, while admitting that "they are in style most proper for the pulpit," confesses that the author seems "often tottering on the verge of laughter, and ready to throw his periwig in the face of the audience." In 1760 Sterne received an additional living at Coxwold in Yorkshire; but subsequent to this time he seems to have lived principally in London or on the continent, leaving his wife and daughter to reside in York. In 1762 he visited France, and between 1764 and 1767 spent much time in southern Europe for the benefit of his health, now seriously impaired. Returning to England, he recorded the impressions of his travels in "The Sentimental Journey," which speedily obtained a European reputation. He died soon after the appearance of the book, of which the first part only was completed, at hired lodgings in London, surrounded by strangers, by whom, it has been said, his body was rifled while he was expiring. In 1775 his daughter Lydia published 8 volumes of his "Letters to his Friends," accompanied by a short autobiographical memoir; and in the same year appeared "Letters to Eliza," consisting of 10 letters addressed by Sterne in March and April, 1767, to "Mrs. Elizabeth Draper, wife of Daniel Draper, Esq., counsellor at Bombay, and at present chief of the factory at Surat," and another collection of letters in one volume. With the exception of a few fragments and a collection of "Seven Letters by Sterne and his Friends," printed for private circulation in 1844, these are his only remaining writings that have been published.—Of the personal character of Sterne, as seen in his life and letters, no favorable impression can be formed. The latter show him to have been indifferent to the duties of his profession, lax

in principle, a bad husband, a faithless lover, offering his affections to 2 or 3 married women at once, the dupe of every coarse flatterer, and false to his professions of virtue or sensibility. With wonderful power to move his readers to tears or laughter, he was rather a great jester than a great humorist, wasting his pathos on the most trivial objects, apparently "to make points and seek applause," and leaving the mind in doubt whether it were genuine feeling or a piece of consummate acting. Masson, however, is of the opinion that "not even the artificiality of his pathos can take away the effect on our sympathies," and that "so far as sensibility can be taught by fiction, his works teach it." The gravest charge brought against him, and one which not even the character of the age in which he lived nor the exquisite accuracy and finish of his diction can palliate, is a tendency to indecency. "There is not a page in Sterne's writings," says Thackeray, with a severity perhaps not wholly merited, "but has something that were better away, a latent corruption—a hint, as of some impure presence; the foul satyr's eyes leer out of the leaves constantly." Sterne was tall and thin, with a hectic and consumptive appearance.

STERNHOLD, THOMAS, an English writer of psalms, born in Hampshire about the commencement of the 16th century, died in 1549. He was groom of the robes to Henry VIII. and Edward VI., and was noted at court for his poetical talents and extreme piety. Impressed with the necessity of procuring a substitute for the profane songs in vogue, he undertook a translation into metre of the Psalms of David, hoping they might become popular with the courtiers. He completed only 87, which were printed in 1549, after his death, with 7 by Hopkins, under the title of "All such Psalms of David as Thomas Sternholde, late Grome of the Kinges Majestyes Robes, did in his life-tyme drawe into Englyshe Metre." The version was completed by John Hopkins and others, and was published in 1562 as "The Whole Book of Psalms, collected into English Metre by T. Sternhold, J. Hopkins, and others, conferred with the Ebreu; with apt Notes to sing them withal;" under which title it was annexed to the "Book of Common Prayer," and continued in use until superseded by the "New Version" of Tate and Brady, first published in 1696. Sternhold was also the author of "Certain Chapters of the Proverbs of Solomon, drawn into Metre" (London, 1549). Sternhold's versions are now remembered only for their antiquity and the prominent place they once occupied in English psalmody.

STESICHORUS, a Greek lyric poet, born in Himera, Sicily, flourished during the first part of the 6th century B.C. He appears to have lived to the age of 80 or 85. The incidents of his life are mostly of doubtful authenticity. He is said to have been educated at Catana, and to have been on friendly terms with Phalaris, tyrant of Agrigentum, and is supposed to have

travelled in Greece. Suidas says that his name was originally Tisias, but was changed to Stesichorus because he was the first to establish a chorus for singing to the harp. By some he has been called the inventor of choral poetry. He wrote in the Doric dialect, intermixed with epic. His poems were chiefly on heroic subjects, although he wrote many on themes more purely lyrical. He was the first of the Greek poets who composed erotic poems. Fragments only of his writings are now extant. The best collection is that of O. F. Kleine, entitled *Stesichori Himerensis Fragmenta*, with a dissertation on his life and poetry (8vo., Berlin, 1828).

STETHOSCOPE. See AUSCULTATION.

STETTIN, a town of Prussia, capital of the province of Pomerania, and of the administrative district of its own name, situated on the left bank of the Oder, 76 m. N. E. from Berlin; pop. in 1858, 53,094. The river is crossed by two bridges, and the town is defended by walls, a citadel, and several forts and outworks. It is entered by 5 principal and several smaller gates, 2 of the former being highly ornamented. The town is old, but it contains several fine squares, and is generally well built. The ancient castle of Stettin, which was the residence of the dukes of Pomerania, contains a collection of northern antiquities, and in the chapel attached to it is the ducal vault. Woolen, linen, cotton, sugar, anchors, &c., are manufactured. The value of the imports in 1854 was \$12,295,800, and of the exports \$6,571,550. In 1858 the total value of the imports was \$17,000,000. The number of vessels entered in 1858 was 3,007, tonnage 541,978; and 58,572 tons of shipping was registered in the port.—In the year 830 a large village and a temple to the Wendish idol Trigloff occupied the present site of Stettin. The temple was destroyed and rebuilt several times, and when Christianity was introduced about the beginning of the 13th century a large treasure was found in it. Stettin has belonged at different times to Denmark, Sweden, and Prussia.

STEUART, SIR JAMES, a Scottish political economist, born in Edinburgh, Oct. 10, 1713, died Nov. 26, 1780. He completed his education at the university of Edinburgh, and in 1734 was admitted to the Scottish bar, at which however he rarely practised. Although of a whig family, he became, through intercourse on the continent with several exiled adherents of the old pretender, imbued with Jacobite doctrines; and having declared for the young pretender in 1745, he was sent by him on a mission to the court of France, where he was residing at the time of the battle of Culloden. The consequence was a compulsory absence from Great Britain for nearly 18 years. He resided during the greater part of this period at Angoulême, and employed his leisure in those studies which were afterward embodied in his books. In 1768 he was permitted to return to Scotland, where he passed the remainder of his life, although it was not until 1771 that he obtained

a free pardon from government. While abroad he published several works on currency, and in 1767 produced his "Inquiry into the Principles of Political Economy" (2 vols. 4to.), the first considerable English work on the subject. (See POLITICAL ECONOMY, vol. xiii. p. 449.) Among his remaining works are: "The Principles of Money applied to the Present State of the Coin of Bengal," "A Plan for introducing an Uniformity of Weights and Measures," &c. A complete edition of his works was edited by his son, Sir James Steuart (6 vols. 8vo., 1805).

STEBEN. I. A. S. W. co. of New York, bordering on Pennsylvania and drained by the Chemung, Canisteo, Tioga, and Conhocton rivers; area, 1,500 sq. m.; pop. in 1860, 66,689. The surface is broken and the soil generally very fertile. The productions in 1855 were 807,604 bushels of wheat, 711,307 of oats, 292,689 of Indian corn, 255,988 of potatoes, 297,289 of apples, 58,749 tons of hay, 1,976,129 lbs. of butter, 886,384 of wool, 113,658 of honey, and 112,287 of maple sugar. There were 9 furnaces, 2 car factories, 42 grist mills, 238 saw mills, 15 shingle factories, 7 newspaper offices, 105 churches, and 841 schools. Iron ore and superior building stone are found. There are 2 or 3 small lakes, and Crooked lake is partly within the county. It is traversed by the Erie, the Buffalo, New York, and Erie, and the Blossburg and Corning railroads, and the Chemung and other canals. Considerable lumber is exported. Seats of justice, Bath and Corning. II. A. N. E. co. of Indiana, bordering on Ohio and Michigan, and intersected by the St. Joseph's and Pigeon rivers; area, 814 sq. m.; pop. in 1860, 10,874. The surface is prairie and woodland, and the soil fertile. The productions in 1850 were 101,190 bushels of Indian corn, 73,141 of wheat, 38,734 of oats, and 5,389 tons of hay. There were 4 churches, and 1,600 pupils in public schools. Capital, Angola.

STEBEN, FREDERIC WILLIAM AUGUSTUS, baron, an officer of the American revolution, born in Magdeburg, Prussia, Nov. 15, 1730, died near Utica, N. Y., Nov. 28, 1794. He was educated at the Jesuit colleges of Neisse and Breslau, and when only 14 years old served as a volunteer under his father, who was an officer in the army of Frederic the Great, and was at the siege of Prague. In 1747 he was appointed a cadet in an infantry regiment, became an ensign in 1749, and a lieutenant in 1753. In 1757 he distinguished himself at the battles of Prague and Rossbach, in 1758 was appointed an adjutant-general, and was in the battles of Kay and Kunersdorf, in the latter of which he was wounded. On the capitulation of Treptow in 1761, he was sent to St. Petersburg as a prisoner of war, but released shortly afterward. In 1762 he was appointed adjutant-general in the king's staff, and had charge of the quartermaster's department. He was a member of Frederic's select academy of young officers who were under his special instruction; and after the siege of Schweidnitz, in which he parti-

disputed, the king presented him with a valuable lay benefice. At the close of the 7 years' war Steuben retired from the army and devoted himself to travel, accompanying the prince of Hohenzollern-Hechingen to a number of the courts of Europe. That prince appointed him in 1764 grand marshal, and general of his guard. Steuben was on terms of intimacy and friendship with a number of the European literary characters and noblemen of his time. In 1777, while on a visit to France, the count St. Germain solicited him to come to America; and Steuben, after frequent interviews with the American commissioners, finally decided to acquiesce. He arrived at Portsmouth, N. H., Dec. 1, 1777, and immediately wrote to congress and to Gen. Washington, tendering his services as a volunteer, and expressing the strongest sympathy with the cause of the colonies. Shortly afterward he proceeded to York, Penn., where congress was in session, was directed to join the army under Washington, and during the winter arrived at Valley Forge. On May 5, 1778, he was appointed inspector-general with the rank of major-general, and by his excellent management greatly improved the condition of the continental troops. In June following he was at the battle of Monmouth. He prepared a manual for the army, which was approved by congress in 1779, and introduced the most thorough discipline; and much of the success of the revolution is to be attributed to his sagacious and rigid regulations. He was a member of the court martial on the trial of Major André. In 1780 he was placed in command of the troops in Virginia, and in January following was active in harassing the British forces under Benedict Arnold. The next summer he was attached to Gen. Lafayette's division, and took an important part in the siege of Yorktown. He was distinguished for his generosity and kindness of heart, and was frequently known to share his last dollar with the suffering soldiers. At various times he contributed most of his clothing and camp equipments to the men, and labored unceasingly to promote their comfort and welfare. After the war, in the impoverished condition of the country, congress was tardy in rewarding him for his services, and he experienced much annoyance and vexatious delay in securing an appropriation for his pay and to reimburse him for personal expenses incurred in providing the soldiers with clothing and arms. In 1790 congress voted him a life annuity of \$2,500. Several of the states passed resolutions acknowledging his eminent services, and voted him tracts of land. New York presented him with 16,000 acres near Utica, forming a township called from him Steuben, on which he settled and passed the remainder of his life, giving portions of the land to his aids, and leasing the remainder to settlers. His life has been written by Francis Bowen in Sparks's "American Biography," and by Friedrich Kapp (New York, 1860).

STEUBENVILLE, a city and the capital of Jefferson co., Ohio, on the Ohio river, 22 m. N. from Wheeling, Va., 85 m. W. from Pittsburg, Penn., and 141 m. E. from Columbus; pop. in 1860, 6,164. It stands on an elevation on the right bank of the river, is well laid out and substantially built, is surrounded by a rich farming and stock-growing country, and is the centre of an important trade. It has 2 cotton factories, 8 woollen factories, a paper mill, an extensive rolling mill, a glass factory, 2 iron foundries, a brass foundry, copperas establishments, machine shops, a coal and carbon oil refinery, an extensive white lead manufactory, a distillery, and a number of large flouring mills. It has 2 banks, 1 daily and 3 weekly newspapers, 12 churches, and a female seminary, which enjoys a high reputation and usually has about 150 pupils. The seminary building is a handsome structure, erected at a cost of \$40,000. The river division of the Cleveland and Pittsburg railroad passes through the city, and it is the present terminus of the Steubenville and Indiana railroad. Abundance of excellent coal is found in the neighborhood.

STEVENS, ABEL, LL.D., an American clergyman, born in Philadelphia, Jan. 19, 1815. He studied at the Wilbraham academy, Mass., and the Wesleyan university, Middletown, Conn. In 1834 he was settled as pastor of a Methodist church in Boston; in 1837 he travelled in Europe, and corresponded extensively with American journals. After his return, he was stationed about 8 years in Providence, R. I. He next removed to Boston in 1840, and took editorial charge of "Zion's Herald," a religious newspaper; in 1852 he removed to New York, and was appointed editor of the "National Magazine;" in 1855 he revisited Europe; and on his return in 1856 was elected editor of the "Christian Advocate and Journal." Dr. Stevens has published "Memorials of the Introduction of Methodism into New England," "Memorials of the Progress of Methodism in the Eastern States," "Church Polity," "The Preaching required by the Times," "Sketches and Incidents, a Budget from the Saddle Bags of an Itinerant," "The Great Reform," and a "History of the Religious Movement of the Eighteenth Century called Methodism" (8 vols., New York, 1859-'62). About 100,000 volumes of his works have been issued.

STEVENS, GEORGE ALEXANDER, an English author, born in London in the early part of the 18th century, died in 1784. He commenced life as a strolling actor, and gradually acquired some reputation as a writer of burlesques and of comic songs. In 1760 he published a novel, "The History of Tom Fool," and a few years later produced an entertainment entitled "A Lecture on Heads," which he gave with remarkable success. He also published a volume of "Songs, Comic and Satirical" (1772); and after his death appeared "The Adventures of a Speculist, compiled from the Papers of G. A. Stevens, with his Life, a Preface, and

Notes" (1788). Of his songs, 100 in number, one only, "The Storm," is still popular.

STEVENS, JOHN, an American inventor, born in New York in 1749, died in Hoboken, N. J., in 1838. In 1787, having accidentally seen the imperfect steamboat of John Fitch, he at once became interested in steam propulsion, and experimented constantly for the next 30 years on the subject. In 1789 he petitioned the legislature of New York for a grant of the exclusive navigation of the waters of that state. The petition was accompanied with draughts of the plan of his steamboat, but the right was not granted. In 1804 Mr. Stevens constructed a propeller, a small open boat worked by steam, and his success was such that he built the Phenix steamboat, which was completed but a very short time after Fulton had finished the Clermont. Fulton having obtained the exclusive right to the navigation of the Hudson, Mr. Stevens placed his boats on the Delaware and Connecticut. In 1812 he published a remarkable pamphlet urging the government to make experiments in railways traversed by steam carriages; and if his plan (which varied very little from the present railways) should prove feasible, he proposed the construction of such a railway from Albany to Lake Erie. The railway engines, he thought, might traverse the roads at a speed of 50 miles or even more per hour, though probably in practice it would be found convenient not to exceed 20 or 30 miles an hour. The details of construction of the roadway and of the locomotives and carriages are given with such minuteness and accuracy, that it is difficult to realize that their only existence at that time was in the mind of the inventor.—ROBERT LIVINGSTON, son of the preceding, also an inventor, born at Hoboken, N. J., in 1788, died there, April 20, 1856. Inheriting his father's mechanical genius and his deep interest in propulsion by steam on land and water, he while young commenced a course of discovery and improvement on these subjects which have given him a very high rank among modern inventors. At the age of 20 he constructed a steamboat with concave water lines, the first application of the wave line to ship building; soon after used for the first time vertical buckets on pivots in the paddle wheels of steamers, suspended the guard beam by iron rods, and adopted a new method of bracing and fastening steamboats; in 1818 discovered the advantage of using steam expansively, and of employing anthracite coal as a fuel for steamers; in 1822 substituted the skeleton wrought iron walking beam for the heavy cast iron walking beam previously in use; first placed the boilers on the guards, and divided the buckets on the water wheels in order to lessen the jar of the boat; in 1824 applied artificial blast to the boiler furnace by means of blowers, and in 1827 the hog frame (so called) to boats, to prevent them from bending at the centre; and during the next 22 years made numerous other

improvements, in the way of balance valves, tubular boilers, steam packing, cut-offs, cross propellers to turn boats as on a pivot, the forcing of air under the bottom of the steamer John Wilson to lighten the draft, &c. He had also during this period invented and put into use the T rail, and used successfully anthracite coal as a fuel for fast passenger locomotives. He had at an early age established steam ferry boats on the Hudson river, and on the organization of the Camden and Amboy railroad took a deep interest in its management, and was for many years its president. In 1818-'14 he invented an elongated bomb shell of great destructive power, and imparted to the government the secret of its construction, in consideration of which he received a large annuity. In 1842 he commenced experiments with a view to the construction of an iron-plated war steamer or battery, which should be shot and shell proof. (See BATTERY.) This battery is not yet completed, but the propriety of finishing it is now (Feb. 1862) under consideration.

STEVENSON, ANDREW, an American statesman, born in Virginia in 1784, died at Blenheim, Albemarle co., Va., June 25, 1857. He studied law and attained a prominent position at the bar. In 1804 he was elected to the house of delegates of Virginia, and after being a member for several sessions was chosen speaker. In 1821 he was elected a representative in congress, and for 18 years held that office, for the last 6 of which he was speaker of the house. He was minister to England from 1836 to 1841, and on his return became rector of the university of Virginia, and devoted the remainder of his life to the duties of that office and to agricultural pursuits.

STEWART, LORD HIGH, in England, the highest officer under the crown, who was formerly known by the Latin title of *magnus seneschallus*. The office was under the Plantagenets hereditary, but since the reign of Henry IV. has been abolished as a permanent dignity, and is conferred for some special occasion, as a trial before the house of peers or a coronation, after which its functions cease. The lord high steward presides at the former, and at the close of the proceedings breaks his wand and dissolves the court.—The office of steward, or steward, also existed from early times in Scotland, and gave name to the royal family of Stuart, in which it had been hereditary from the time of Malcolm III. (1056-'93) till the accession to the throne of Robert (II.) Stuart, grandson of King Robert Bruce, in 1371.

STEWART. I. A. W. S. W. co. of Ga., bounded W. by the Chattahoochee, separating it from Alabama, and drained by several of its tributaries; area, 700 sq. m.; pop. in 1860, 18,423, of whom 7,885 were slaves. The soil is fertile. The productions in 1850 were 684,449 bushels of Indian corn, 171,791 of sweet potatoes, 16,390 lbs. of rice, and 19,165 bales of cotton. There were 9 farm implement factories, 4 grist mills, 7 saw mills, 3 tanneries,

33 churches, and 660 pupils attending public schools. Capital, Lumpkin. H. A. N. W. co. of Tenn., bordering on Ky., intersected by the Cumberland river, and bounded W. by the Tennessee; area, 700 sq. m.; pop. in 1860, 9,888, of whom 2,405 were slaves. The surface is undulating and the soil very fertile. The productions in 1850 were 584,050 bushels of Indian corn, 22,020 of sweet potatoes, 43,225 of oats, 290,320 lbs. of tobacco, and 92,625 of butter. There were 11 grist mills, 9 saw mills, 5 forges, 8 tanneries, 42 churches, and 248 pupils attending public schools. Capital, Dover.

STEWART, CHARLES, an American naval officer, born in Philadelphia, July 28, 1778. He entered the navy as lieutenant in March, 1798, and performed his first service in the frigate *United States*, Com. John Barry. He remained in this ship, which was employed in the West Indies for the protection of American commerce against French privateers, until July, 1800, when he was appointed to the command of the schooner *Experiment*, of 12 guns, upon the same station. While lying in Rupert's bay, island of Dominica, he ascertained that an impressed American seaman was on board H. B. M. ship *Siam*, whose release he demanded, and after some negotiation obtained from the English commander. On Sept. 1 the *Experiment* fell in with and captured, after an action of 10 minutes, the French schooner *Deux Amis*, of 8 guns; and soon after, while cruising near the island of Barbuda, she captured, after a very short action, the French schooner *Diana*, of 14 guns. In addition to these two captures, she recaptured a number of American vessels which had been taken by French privateers. In 1801 the *Experiment* arrived at Norfolk, Va., and was sold out of service; and in the following year Lieut. Stewart made a short cruise as first lieutenant of the frigate *Constellation*, employed in the blockade of Tripoli. Upon the termination of this cruise he was appointed to command the brig *Siren* in the squadron of Com. Edward Preble, and participated in the naval operations of 1804 against Tripoli. He coöperated with Lieut. Com. Stephen Decatur, jr., in the destruction of the frigate *Philadelphia* on Feb. 16, as well as in the several attacks on the city and its defences; and for his services in the bombardment of Aug. 8, 1804, he received the thanks of Com. Preble in general orders. He was promoted to the rank of master and commander, and upon the conclusion of peace with Tripoli returned to the United States in command of the frigate *Constellation*. In 1806 he was captain, and was employed in superintending the construction of gun boats at New York. Upon the declaration of war by the United States against England in 1812, the government resolved to withdraw the American ships of war from the ocean and devote them to harbor defence, upon the ground that they would soon be captured by the overwhelming naval force of England; but

Capt. Stewart and William Bainbridge united in most earnest efforts to induce a change of policy in this respect, and succeeded. In conformity with their suggestions, the ships of war were ordered to sea, and in Dec. 1812, Capt. Stewart was appointed to the frigate *Constellation*, then lying at Norfolk. In the summer of 1818 he was transferred to the *Constitution*, there seeming to be no possibility of his eluding with the *Constellation* a close blockade of Norfolk, which was maintained by a strong British squadron. In December he sailed from Boston upon a cruise, which extended to the coasts of Surinam, Berbice, Demerara, and the Windward islands, resulting in the capture of the British schooner of war *Pioton*, of 14 guns, a letter of marque under her convoy, and several merchant vessels. In April, 1814, the *Constitution* was chased into the port of Marblehead by the British frigates *La Nymphe* and *Junon*. About the middle of December following, Capt. Stewart sailed in the same ship upon a second cruise, and on Feb. 20 he fell in with and captured, after an action of 40 minutes, H. B. M. ship *Oyane*, Capt. Falcon, mounting 84 guns, with 185 men, and the sloop of war *Levant*, Capt. Douglass, of 21 guns and 156 men. The *Constitution* mounted 52 guns with 470 men. The action was fought at night, and at the commencement of it the three ships were close-hauled and formed nearly an equilateral triangle, the *Constitution* being to windward. By judicious manœuvring she forced her antagonists down to leeward, and raked them both, while she avoided being raked herself. No British official account of this action has been published. By some statements the joint loss of their two ships is given at 41, while that of the *Constitution* was but 8 killed and 12 wounded. On March 10 the *Constitution* arrived at Port Praya, Cape Verd islands, with her prizes, and while a cartel was preparing to convey the prisoners to the United States a British squadron appeared in the offing. Capt. Stewart believed that the neutrality of the port would not be respected, and therefore cut his cables and put to sea, the prizes following. The squadron was composed of two line-of-battle ships and a heavy frigate, and an active chase ensued, which resulted in the recapture of the *Levant*. The *Oyane* arrived at New York on April 15, and the *Constitution* about the middle of May. Civic honors were bestowed upon Capt. Stewart by New York and Philadelphia; congress voted him a gold medal, and silver ones to each of his commissioned officers, and also passed a vote of thanks to him, his officers, and men; and Pennsylvania voted him a sword. From 1816 to 1820 Com. Stewart commanded a squadron in the Mediterranean, the *Franklin* ship of the line bearing his flag. In 1821 he hoisted his flag in the same ship for the Pacific station, where he commanded 3 years. His later services have been upon the board of navy commissioners from 1830 to 1838, and in

command of the home squadron and of the naval station at Philadelphia. He has also rendered important services in the organization of the navy, and submitted to the navy department at different times valuable papers on the subject. In 1857 he was placed upon the reserved list of the navy, his advanced age, in the opinion of the board appointed under the act of congress of Jan. 16 of that year, leaving them no discretion in his case; but in March, 1859, he was placed upon the active list by special legislation under a new commission as senior flag officer. He was recently at his own request relieved from the command of the navy yard at Philadelphia, and now (1862) resides upon his estate at Bordentown, N. J.

STEWART, DUGALD, a Scottish metaphysician, born in Edinburgh. Nov. 22, 1758, died there, June 11, 1828. The son of Dr. Matthew Stewart, a clergyman and mathematical professor, he was educated at the high school and university of his native city, attracted notice by his taste and capacity for purely philosophical studies, heard the lectures of Reid at Glasgow during one term (1771-'2), was recalled to Edinburgh to act as his father's substitute in the charge of the mathematical classes, and was formally elected conjoint professor as soon as he had completed his 21st year. For several years he was prominent in the weekly debates of the speculative society, before which he also read essays on philosophical subjects. He conducted the class in moral philosophy for one session (1778-'9), during the absence of Prof. Ferguson, upon whose resignation in 1785 he was elected his successor; and as a lecturer in this department he enjoyed the highest reputation during the next 24 years. "Probably no modern," says Mackintosh, "ever exceeded him in that species of eloquence which springs from susceptibility to literary beauty and moral excellence; which neither obscures science by prodigal ornament, nor disturbs the serenity of patient attention; but, though it rather calms and soothes the feelings, yet exalts the genius, and insensibly inspires a reasonable enthusiasm for whatever is good and fair." Lord Cockburn describes him as "one of the greatest of didactic orators. Had he lived in ancient times, his memory would have descended to us as that of one of the finest of the old eloquent sages." "All the years I remained about Edinburgh," says James Mill, "I used, as often as I could, to steal into Mr. Stewart's class to hear a lecture, which was always a high treat. I have heard Pitt and Fox deliver some of their most admired speeches, but I never heard any thing nearly so eloquent as some of the lectures of Prof. Stewart." It was his custom to speak from notes, not to read from full copy, a method suited to his peculiar powers, since it allowed scope to the imagination and the feelings. His aim was always moral and practical more than speculative, to portray ideal perfection and advance the harmonious

culture of all the faculties, intellectual, moral, and sensitive, rather than to teach definite solutions of intellectual problems; and his lectures therefore proceeded from psychology to theories of character and manners, life and literature, taste and the arts, politics and natural theology. The prominence which he assigned to the last subject, as the highest branch of metaphysics, was designed, as he explained, to resist the prevalent sceptical tendencies of the era of the French revolution. From the beginning he gave lectures on the theory of government as a part of the course on moral philosophy, and in 1800 he first delivered a special course on the new science of political economy. He showed no marked advances beyond the doctrines of the "Wealth of Nations," but made modifications and new applications, and had the courage to canvass fundamental questions and to maintain liberal opinions before the youth of Great Britain at a time when hostility to revolutionary tendencies prejudiced all political speculation. He did not appear as an author till 1792, when he published the first volume of "Elements of the Philosophy of the Human Mind." In the following year he published his "Outlines of Moral Philosophy," and read before the royal society an account of the life and writings of Adam Smith, which was printed in the "Transactions," and was followed by his biographies of Dr. Robertson (1796) and Dr. Reid (1802). Nothing else appeared from his pen till the publication of the "Philosophical Essays" in 1810, though in this interval he prepared the matter of all his other writings, with a single exception. In 1806, on the accession of a whig administration, the sinecure office of gazette writer of Scotland was created for him, to which the salary of £300 per annum was attached. He accompanied in that year Lord Lauderdale on his mission to Paris. His health was failing, when in 1809 it received a severe blow by the death of his younger son, and in the following year he was obliged to retire from active duty as a professor, his successor being Dr. Thomas Brown. To divert his thoughts from his affliction, he interrupted his more elaborate work on the mind for the easier task of preparing the volume of "Philosophical Essays," which reached 8 editions in 7 years. He had meantime removed to Kinneil house, on the shore of the frith of Forth, 20 miles from Edinburgh, where he passed the remainder of his life. From this retreat he sent forth in succession the second volume of the "Elements of the Philosophy of the Human Mind" (1814); a preliminary dissertation to the supplement of the "Encyclopædia Britannica," entitled "A General View of the Progress of Metaphysical, Ethical, and Political Science since the Revival of Letters" (part i., 1815; part ii., 1821); the third volume of the "Elements" (1827); and the "Philosophy of the Active and Moral Powers" (1828), which was completed only a few weeks before his death. He had been

struck with paralysis in 1822; but though the malady deprived him of the power of speech and of the use of his right hand, it did not impair the vigor or activity of his mind, and by the aid of his daughter as an amanuensis he continued his literary studies and exertion, until a fresh paralytic shock which soon terminated fatally. A disciple of Reid, adhering to the traditions of the Scottish school, and remarkable rather as an eloquent and elegant writer than as a profound thinker, he did not even reduce to a system the theories of his predecessors; but he rendered them attractive by profuse and exquisite illustrations, and made important improvements in phraseology and classification, especially by proposing the "fundamental laws of human thought or belief" instead of the "instinct" or "common sense" of his master.—His collected works were edited by Sir William Hamilton (10 vols., Edinburgh, 1854-'8). His lectures on political economy were first published in this edition. The last volume contains a memoir by John Veitch, with selections from his correspondence.

STEWART, JOHN, an English traveller, born in London in the first half of the 18th century, died there in 1822. He went to Madras in 1768, in the civil service of the East India company, but at the end of two years resigned his office and commenced a series of pedestrian tours through Hindostan, Persia, Nubia, and Abyssinia, in the course of which he was at different times in the service of the nabob of Arcot and of Hyder Ali. He next walked to Europe by the way of the Arabian desert; and having perambulated every part of Great Britain, he crossed the Atlantic and visited on foot many parts of the United States. The last 10 years of his life were passed in London.

STEWART, MATTHEW, a Scottish clergyman and mathematician, father of Dugald Stewart, born at Rothesay, in the isle of Bute, in 1717, died in Ayrshire, Jan. 23, 1785. He was educated at Glasgow and Edinburgh, and entered the church. The favorite pupil of Simson, he assisted his master in investigating the porisms of Euclid, and, pursuing the same subject, discovered a series of ingenious and curious propositions, published under the title of "General Theorems" (1746). This work caused him to be elected the successor of Maclaurin in the mathematical chair of the university of Edinburgh in 1747, which position he held till 1772. He retired 8 years later to an estate in Ayrshire. His aim as a mathematician was to cherish the forms of ancient demonstration even for such problems as the algebraic calculus alone had been thought able to resolve. Thus he solved Kepler's problem by the methods of the ancients (1756). His other publications were "Four Tracts, Physical and Mathematical" (1761), and an "Essay on the Sun's Distance" (1763), in which he adhered to geometric simplicity, but stopped far short of the results since attained in physical astronomy.

STEWART, ROBERT HENRY, MARQUIS OF LONDONDERRY. See CASTLEREAGH.

STEYER, or STEIER, a town and the capital of the circle of Traun in Upper Austria, 19 m. S. E. from Linz, at the confluence of the Steyer and Enns; pop. about 11,000. The town proper stands between the two rivers, surrounded by crenellated walls flanked with towers; there are two suburbs on the opposite shores of the Enns and Steyer, each connected with the town by a bridge. Steyer is largely engaged in the manufacture of cutlery and hardware, and is often called the Austrian Sheffield.

STICKLEBACK, the popular name of the acanthopterous fishes of the mailed-cheeked family or *sclerogenida*, and genus *gasterosteus* (Linn.). They are also called banstickles, and are the *épinoches* of the French. Most of the species are found in fresh water, and are from 2 to 8 inches long; the sides are more or less protected by bony plates, the other parts being without scales; very small and crowded teeth on the jaws, none on the palate; branchiostegal rays 8; tail keeled on both sides; ventrals abdominal, reduced to a strong spine, used as a weapon, and 1 or 2 soft rays; free spines, from 8 to 15 in front of the dorsal, which is supported by soft rays; bones of the pelvis large, forming an abdominal sternum. They are very active, pugnacious, and voracious fishes, feeding on aquatic insects and worms, and the fry of other fish, in the latter way often doing great mischief in fish preserves; they sometimes spring entirely out of water. They are best known, however, for the parental care which the males take of the eggs and offspring; though Aristotle knew, 22 centuries ago, that some species of fish make nests for the reception of their spawn, it is only within the last 20 years that the fact has been generally admitted by naturalists. They breed in summer, and may be conveniently watched in aquaria, making and guarding their nests and protecting the young fry; the males are the builders, and at this season have the throat carmine red and the eyes brilliant bluish green, the other parts above being ashy green and the abdomen silvery and translucent. The nest is made of delicate vegetable fibres, matted into an irregular circular mass cemented by mucus from the body, an inch or more in diameter, with the entrance near the centre; when the nest is prepared the female is enticed or driven in, and there deposits her eggs, which are fecundated by the male; the latter remains constantly on guard, swimming in the neighborhood, driving away intruders with great ferocity, frequently putting in his head to see if all is right, and fanning the water with the pectorals and caudal to secure free circulation and ventilation for the eggs. They are frequently seen shaking up the eggs, and carrying away impurities in the mouth; the young are hatched in 2 or 3 weeks; any of the small fry getting outside of the nest are instantly seized in the mouth of the parent and put back; there

are about 40 young to a nest, and if any escape far beyond its protection they are eagerly devoured by other fish of the same species always on the watch. This fish takes as good care of its young as does the hen of her chickens; for interesting details on its nidification see "Annals and Magazine of Natural History," 2d series, vol. x., pp. 241-'8 and 276-'80 (London, 1852). The common European species (*G. aculeatus*, Linn.; since separated into 8 by Cuvier) has 8 spines in front of the dorsal, and is found in almost every pool and rivulet in Great Britain; in some years it has been so abundant in Lincolnshire as to be used for manure. The *G. spinachia* (Linn.) has 14 or 15 free spinous rays on the back, and has an elongated head and body; it is a marine species, found in the northern seas of Europe. The best known of the many species in the United States are the 2-spined stickleback (*G. biaculeatus*, Mitch.), which is found from Labrador to New York, 2 inches long, olive green above, yellowish green on sides, with 2 distant spines on the back and a 3d near the dorsal; and the 4-spined stickleback (*G. quadricus*, Mitch.), of the Massachusetts and New York coasts. Other species have 8 to 10 spines, and the males in all assume the red tint in the breeding season, both in salt and fresh water.

STICKNEY, SARAH. See ELLIS, WILLIAM.

STIEGLITZ, CHRISTIAN LUDWIG, a German writer upon architecture, born in Leipsic, Dec. 12, 1756, died there, July 17, 1836. He was educated for the legal profession, but devoted himself chiefly to architectural and antiquarian studies, and published treatises on architecture (1786), on the use of the grotesque and arabesque (1792), and a history of the architecture of the ancients (1792). His most important works are: *Encyklopädie der Baukunst der Alten* (5 vols., Leipsic, 1792-'8); *Zeichnungen aus der schönen Baukunst* (1801), containing engravings of select specimens of modern architecture; *Ueber altdeutsche Baukunst* (1820), which contributed to diffuse and direct a taste for mediæval art; and a valuable *Geschichte der Baukunst vom frühesten Alterthums bis in die neuesten Zeiten* (Nuremberg, 1827). He also published poems and dissertations on literary and antiquarian subjects, and contributed to journals and to Ersch and Gruber's *Encyklopädie*.

STIEGLITZ, HEINRICH, a German poet, born at Arolsen in 1803, died in Venice, Aug. 24, 1849. He completed his studies at Berlin, where in 1828 he became librarian. He married, taught in the gymnasium, published poems with moderate success, and became morbidly melancholy. His wife, who was thought to be a woman of genius, eager for his fame as a poet, and believing that only a great sorrow could restore his mind to health and activity, committed suicide in 1834, after an excursion with him in Russia. Her letters and diary were collected by Mundt in *Charlotte Stieglitz, ein Denkmal* (Berlin, 1835). Her death had

not the effect which she anticipated, and from that time he is stated to have travelled hurriedly, as if accursed, from city to city, publishing occasional poems. His best productions are: *Bilder des Orients* (4 vols., Leipsic, 1831-'8); *Stimmen der Zeit in Liedern* (2d ed., 1834); and *Das Dionysusfest* (Berlin, 1836).

STIGMARIA. See COAL PLANTS.

STILES, EZRA, D.D., an American clergyman, born at North Haven, Conn., Dec. 10, 1727, died in New Haven, May 12, 1795. He was graduated at Yale college in 1746, and was a tutor there from 1749 to 1755. Dr. Franklin having sent an electrical apparatus to Yale college, Mr. Stiles, with one of his fellow tutors, entered with great zeal upon this then new field of philosophical investigation, and performed the first electrical experiments ever made in New England. At the same time he was pursuing the study of theology, and commenced preaching in June, 1749. In April, 1750, he visited the Housatonic tribe of Indians at Stockbridge, and preached among them so acceptably that he was earnestly solicited by the society for propagating the gospel among the Indians to take charge of the mission there, but his imperfect health obliged him to decline the proposal. He then studied law, in 1753 was admitted to the bar, and practised the profession at New Haven for the two following years. In Feb. 1755, he pronounced a Latin oration in honor of Dr. Franklin, on occasion of his visiting New Haven, and was from that time in intimate relations with him till they were terminated by death. In 1756 he became pastor of the 2d church in Newport, R. I., and during his residence there devoted himself assiduously to his professional duties, and found time also for literary and scientific investigations, corresponding with learned men in almost every part of the world. In 1767 he began the study of the Hebrew and other oriental languages, and pursued it with great avidity. His congregation at Newport being entirely broken up by the British occupation of the place, in May, 1777, he removed to Portsmouth, N. H., to become pastor of the North church. In September following he was elected president of Yale college, and shortly after professor of ecclesiastical history in connection with the presidency, and in June, 1778, entered on his official duties. After the decease of Professor Daggett in 1780, he discharged the duties of professor of divinity, beside which he gave each week one or two dissertations on some philosophical or astronomical subject. His labors for the college were intense and uninterrupted during the residue of his life. He published a funeral oration in Latin on Governor Law (1751); a Latin oration on his induction to his office as president (1778); an "Account of the Settlement of Bristol" (1785); "History of three of the Judges of Charles I." (1795); and 5 occasional sermons. His life has been written by James L. Kingsley, in Sparks's "American Biography," 1st series, vol. vi.

STILICHO, FLAVIUS, a Roman general, assassinated Aug. 23, A. D. 408. He was the son of a Vandal officer of the cavalry under Valens, rose to high rank during the reign of Theodosius, by whom he was sent in 384 to Persia to ratify a treaty with the monarch of that country, was rewarded for his services on that occasion with the hand of Serena, the niece and adopted daughter of Theodosius, and soon became master-general of all the cavalry and infantry of the western empire. Jealousy sprang up between him and Rufinus, on whom Theodosius conferred the government of the East, which soon ripened into intense hatred. In 394 Stilicho became governor of the West, as guardian of Honorius, whom Theodosius had proclaimed Augustus; and when Theodosius died in 395, leaving to Honorius the empire of the West, and to Arcadius that of the East, Stilicho immediately passed the Alps in the depth of winter, spread terror among the barbarians by his bold and rapid operations, and having in a single summer established a firm peace on the border, returned to Milan, and prepared to march in person to Constantinople, ostensibly against Alaric and to lead back the eastern legions, but really to break the power of Rufinus. Being met near Thessalonica by a message from the Byzantine court that his nearer approach would be considered an act of hostility, he went no further, but engaged Gainas, the leader of the Gothic allies of Arcadius, to put Rufinus to death, which he accomplished in Nov. 395. Stilicho, however, gained little by this proceeding, as Arcadius fell into the hands of the eunuch Eutropius and Gainas, both of whom became bitterly hostile to himself. Several attempts were made to assassinate him, and the senate of Constantinople issued a decree declaring him an enemy of the republic, and confiscating his possessions in the East. Stilicho, who did not desire to involve the empire in civil war, made no effort to interfere with the ministers of Arcadius. In 396 Alaric ravaged the northern parts of Greece, and penetrated into the Peloponnesus. Stilicho at the head of a powerful army sailed from Italy to chastise the invaders; but Alaric escaped into Epirus, of which he took possession, and concluded a treaty with the ministers of Arcadius, by which he was made master-general of the province of Illyricum. Stilicho retired to Italy, where in 398 a marriage was celebrated between his daughter Maria and Honorius. In 400 Alaric invaded Italy, and Honorius was only prevented from flying with the court to Gaul by Stilicho, who hastened to collect his scattered troops from Rhætia, Gaul, and Germany, while Alaric seems to have been delayed by the siege of Aquileia, and to have returned to the Danube for reinforcements. In 408 that leader besieged Milan, from which the emperor fled, and the garrison was reduced to the last extremity when the rapid approach of Stilicho changed the position of the contending parties. Alaric was attacked in his camp at Pollentia,

and after a bloody battle was defeated, and again soon after under the walls of Verona. Alaric now departed from Italy, and Stilicho in 404 received the honor of a triumph in Rome. Intrigues were still carried on against him in the Byzantine court, and he now formed an alliance with his late enemy against the emperor of the East. His preparations, however, were disturbed by the invasion of Italy in 405 by Radagaisus, at the head of a mixed multitude of Vandals, Suevi, Burgundians, Alani, and Goths. But while they were besieging Florence, Stilicho cut off their communications and supplies by strong lines of circumvallation, and hunger and disease forced them to capitulate. Radagaisus was put to death, and his men were sold as slaves; but the other portion of this horde, which had not entered Italy, ravaged Gaul, from which the garrisons had been withdrawn, and which Stilicho, intent chiefly on the preservation of Italy, was obliged to leave to its fate. Meanwhile Alaric had become impatient of the delay, and marching to Æmona on the borders of Italy, sent to the emperor of the West a demand for the promised subsidies. The influence of Stilicho secured to the Gothic king the payment of 4,000 pounds of gold; but a large party were indignant at his supposed partiality for the barbarians, and his power at court was also secretly undermined by the arts of the eunuch Olympius, whom he himself had introduced into the imperial palace. The latter represented to Honorius that he was without authority in his own kingdom, and that his death was meditated by Stilicho, who designed placing the imperial crown upon the head of his son Eucherius. On the death of Arcadius in May, 408, Honorius proposed to visit Constantinople as the guardian of Theodosius, the infant son of that emperor. From this project he was diverted, but he could not be dissuaded from showing himself to the camp at Pavia, filled with Roman troops and enemies of Stilicho. Immediately after his arrival there, through the agency of Olympius, the friends of Stilicho, some of the most illustrious officers of the empire, were murdered. Stilicho was in the camp of the barbarian allies at Bologna, and immediately called a council of his friends, who demanded to be led against the murderers. But he hesitated, and his friends, indignant at his want of resolution, left him to his fate. An unsuccessful attempt to assassinate him was made by Sarus, a Goth, but he succeeded in escaping, and threw himself into the hands of his enemies in Ravenna, and took refuge in a church. From this sanctuary he was led out, and no sooner had he passed the threshold than he was slain by Count Heraclian at the head of a troop of soldiers. His family and friends were persecuted, and many of them put to death, and his own name was branded with the title of public enemy, and his estate confiscated. His qualities and services have been celebrated by the poet Claudian.

STILLING, JUNG. See JUNG-STILLING.

STILLINGFLEET, EDWARD, an English author and prelate, born in Cranbourn, Dorset, April 17, 1635, died in London, March 27, 1699. He was educated at St. John's college, Cambridge, at the age of 18 obtained a fellowship, and in 1657 was presented to the rectory of Sutton. Subsequently he became chaplain in ordinary to Charles II., and dean of St. Paul's, and in 1689 bishop of Worcester. His first work, "Irenicum, or the Divine Right of particular Forms of Church Government Examined" (1659), was distinguished by a toleration inclining, as the high church party thought, toward Presbyterianism, and which he subsequently confessed "showed his youth and want of due consideration." His views however soon took another direction, and he combated Roman Catholics and nonconformists with equal energy. Of this character were his "Rational Account of the Grounds of Protestant Religion" (fol., 1664), written in vindication of Archbishop Laud's views in his conference with Fisher, the Jesuit; his "Discourse concerning the Idolatry practised in the Church of Rome" (1671), which he afterward defended against several antagonists; a sermon against the nonconformists entitled "The Mischiefs of Separation," which was answered by Owen, Baxter, and others, to whom Stillingfleet published a rejoinder entitled "The Unreasonableness of Separation" (4to., 1681); and a variety of less important tracts against the Roman Catholics, the Socinians, &c. He is, however, better known at the present day by his "Origines Sacre, or Rational Account of the Grounds of Natural and Revealed Religion" (4to., 1662), which is still regarded as one of the ablest defences of the truth of revelation; and by his "Origines Britannicæ" (1685), an account of the ecclesiastical history of Britain from the introduction of Christianity to the conversion of the Saxons. After his consecration he devoted himself with great energy to diocesan reforms, and participated with distinction in parliamentary debates. He wrote several more polemical tracts and a number of miscellaneous pamphlets, and in the latter part of his life engaged in a sharp controversy with Locke on the latter's definition of substance and theory of ideas in general. His works were printed in 1710 in 6 vols. fol., to which was added in 1735 a volume of his miscellaneous works.

STILLMAN, SAMUEL, D.D., an American clergyman, born in Philadelphia, Feb. 27, 1737, died in Boston, March 12, 1807. His parents removed in his childhood to Charleston, S. C., where he studied theology; and he was licensed to preach in 1758, and ordained as an evangelist of the Baptist church in 1759. In 1761 he removed to Bordentown, N. J., and in 1763 to Boston, where in 1765 he became pastor of the first Baptist church, which relation he held till his death, being for many years regarded as the most eloquent and popular

preacher in Boston. He was one of the founders and incorporators of Brown university, and the schools of Boston were also indebted to his efforts for much of their efficiency. He was active in the promotion of all humane institutions, and was an officer of several of them at the time of his death. He was a member of the convention which framed the constitution of the United States. During his lifetime Dr. Stillman published a great number of sermons and addresses, some of which, with others previously unpublished, were collected in an 8vo. volume in 1808.

STILLWATER. See SARATOGA, BATTLE OF.

STILT, a wading bird of the avocet family, and genus *himantopus* (Briss.), so called from the length and slenderness of the legs. The bill is long, straight, slender, and pointed, with a groove on each side to the middle; wings long and pointed, 1st quill much the longest; tail short and nearly even; legs very thin and long, with scaled tarsi; toes moderate, joined at the base, with a wide membrane between the outer and middle toes; hind toe wanting; claws small and sharp; neck long. Of the half dozen species found in various parts of the world, may be mentioned two, the black-necked and the white stilt, the former American and the latter European. The black-necked stilt (*H. nigricollis*, Vieill.) is about 14 inches long, black above, with forehead, lower parts, rump, and tail white; bill black, and legs red. It is found as far N. as the middle states in spring, going S. beyond the limits of the United States in autumn; though the legs seem disproportionately long, it is a graceful bird, and frequents salt marshes in flocks of 6 to 20, delighting to wade knee-deep in search of aquatic larvæ and insects, snails, and small fry; the nests are built in company, at first upon the ground, from which they are gradually raised by successive additions; the eggs are usually 4, of a pale yellowish clay color, with large irregular blotches and lines of brownish black; though the gait on first alighting is rather unsteady, the flight is rapid and regular, the legs extending behind; the flesh is indifferent eating. The white stilt (*H. melanopterus*, Meyer) is of about the same size, and with similar habits, preferring, however, the edges of fresh water streams; it is white, with the back and wings shining greenish black, and legs red; it is found in S. E. Europe, Asia, and Africa; the bill is 3 inches and tarsus 4.

STIRLING, a parliamentary and municipal burgh of Scotland, capital of Stirlingshire, on the river Forth, 81 m. W. N. W. from Edinburgh; pop. of the burgh in 1861, 13,846. The town is built on a height at the head of the navigation of the river, which is crossed by two bridges and a railroad. Many of the public buildings are very ancient, and the castle is supposed to have been originally built by the Romans. It stands upon a rocky height more than 200 feet above the plain, and forms a conspicuous object from several of the sur-

rounding counties. The castle of Stirling holds a prominent place in the history of Scotland, and is connected with most of the important events that occurred in that kingdom before it was annexed to England. The royal palace is still standing in an apartment of which the earl of Douglas was mortally stabbed by James II.; and in another room the same James, as well as James V., was born. There is also a palace commenced by the latter and finished by his daughter Mary. The parliament house has been much defaced by being occupied by troops. Part of the royal chapel is used as an armory. There are several ancient churches and some modern ones within the town, beside numerous schools. The town house is very ancient, and the old residence of the earl of Mar is a very curious building. Stirling has some manufactures, the principal of which are woollens of different descriptions, leather, ropes, &c. The river is shallow, but a considerable trade is carried on. The Scottish central railway passes it, and 8 others have their termini at the town. The salmon fishery of the Forth is valuable.

STIRLING, EARL OF. See **ALEXANDER, WILLIAM.**

STIRLING, WILLIAM, a Scottish author, born at Kenmure, near Glasgow, in 1818. He was graduated at Trinity college, Cambridge, in 1839, and soon after turned his attention to the study of Spanish literature, history, and art, for which purpose he travelled and resided several years in Spain. In illustration of these subjects he has published "Annals of the Artists of Spain" (3 vols. 8vo., 1849), "The Cloister Life of the Emperor Charles the Fifth" (1852), and a life of Velasquez, entitled "Velasquez and his Works" (12mo., 1855). In 1852 he was elected in the conservative interest a member of parliament for Perthshire, which constituency he still represents.

STIRLINGSHIRE, a central county of Scotland, bounded by the counties of Perth, Clackmannan, Linlithgow, Lanark, and Dumbarton; area, 462 sq. m.; pop. in 1861, 91,926. The principal towns are Stirling, Falkirk, Alva, Bannockburn, and Denny. The chief rivers are the Forth, Avon, Kelvin, Endrick, and Carron. Half of Loch Lomond belongs to Stirlingshire. Loch Coulter, Loch Elrigg, and some others are also in the county; and the W. end of Loch Katrine forms the N. E. boundary for a short distance. Ben Lomond, in the N. W. part of the county, rises to the height of 3,197 feet above the sea. Coal and iron are mined, and woollen and cotton goods are manufactured; the iron works situated at Carron are among the largest in the world.

STIVER, a Dutch copper coin, of the value of about two cents in the currency of the United States.

STOAT. See **ERMINE.**

STOBÆUS, JOANNES, the compiler of a valuable collection of passages from Greek authors, probably born at Stobi in Macedonia, lived in the latter half of the 5th century.

Stobæus called his whole work an "Anthology," and divided it into 4 books; but it has come down in a somewhat different form and as two separate works. The original 1st and 2d books are now entitled "Physical and Ethical Extracts," and the remainder the "Anthology," or by the Latin writers *Sermones*. These works, with extracts from many still extant ancient writers, contain passages from a large number of writers whose works are lost, and who are not otherwise known. A complete edition of both the "Extracts" and the *Sermones* was published by Tauchnitz (3 vols. 16mo., Leipzig, 1838).

STOCK EXCHANGE, the appellation originally given to the building in which stocks were bought and sold, but which has now come to signify transactions of all kinds in stocks. In England the term stocks is confined to the government stocks, annuities, &c., and the term shares is used for the capital or stock of railroad, banking, and other companies; but in the United States the obligations of the national debt, as well as of states, counties, and cities, and the shares of railroads, banks, mining, manufacturing, and insurance companies, are all called stocks. In France the word *rentes* has the same limitation as stocks in England. The amount of the public debt of Great Britain at the end of 1860 was £801,477,741, and the interest £26,833,469. The debt of France in 1860, of which the *rentes* are the evidences, was \$1,714,000,000, and the interest on it \$114,000,000. The dealing in the various stocks, bonds, and annuities is the business of the stock exchange, and the dealers in them are usually known as stock brokers and stock jobbers. In New York the traffic in stocks is of two kinds, the regular sales at the first and second boards, and the operations of the street. The first are, or are supposed to be, legitimate in their character, and the sales *bona fide*; the second are speculative in character, often illegal, and as often mere gambling or betting by parties without capital. The board of brokers in New York is composed of 200 regular members, who are men of reputed wealth, and who at their two daily sessions, either on their own account or on account of persons for whom they act, purchase or sell the various stocks which are called in order. Many of these sales and purchases are made for speculative purposes, but very seldom on account of brokers themselves. The delivery of stocks and the payment at full price is the almost invariable custom. It is only when a failure occurs that differences are fixed between members of the board. When a member of the board fails to deliver or pay for stocks as agreed, his name is struck from the list. He may be reinstated, however, upon effecting a settlement with his creditors. The efforts by one class of brokers to depreciate stocks, and by another to enhance their value, have led to the technical names of bears and bulls, and in the French *bourses* to the similar terms *baisseurs* and *hausseurs*. (See **BEARS**

AND BULLS.) The measures resorted to for the purpose of raising or depressing values are extraordinary and not always creditable.—The stock exchange has its own peculiar terms, not generally understood by outsiders. The phrase "buyer's option," added to the memorandum of a sale of stocks, implies that the purchaser, who buys at 80 or 60 days, can at his own choice call for the delivery of the stocks at any time within the period by giving one day's notice and paying interest at 6 per cent. up to the time he calls. Such purchases are usually made at a little above the cash price. "Seller's option," on the contrary, is a little below the cash price, and the seller has the right to deliver any day within the limited time, by giving one day's notice, receiving interest up to the time of delivery. A "corner" is an operation by several brokers, who form a clique to compel others to pay a heavy difference on the price of stock. Sometimes the clique purchase gradually a large amount of stock on time, buyer's option; they next sell nearly the same amount on time, seller's option, so as to secure an eventual market for their stock; then buy for cash, thus raising the price, and make a sudden call for the stock they have purchased on buyer's option, which, if they have calculated correctly, compels the parties from whom they have purchased to buy of them at a high price in order to deliver at a low one. The operation is attended with considerable hazard. A "lame duck" is a broker who is unable to respond with the shares or money when contracts mature. A "spread eagle" is the operation of a broker who sells a given quantity of stock on time, say 60 days, buyer's option, and buys the same quantity at a lower price, on the same time, seller's option. If both contracts run their full time, he makes his difference; but if the buyer or seller compel him to deliver before the time, he may be seriously embarrassed. The "street" or "the curbstone brokers," as the board call them, though often men of probity and honor, and transacting a very large amount of business, are not governed by as strict rules, nor as careful to abide by the letter of the law. Many of them are "lame ducks." They have a room adjoining that occupied by the board, and during its sessions in communication with it. Their operations are mostly speculative, and there are few of the tricks of the trade in which they are not skilled. Few of them possess any considerable capital, and if they are successful one day, they often lose the next.—In Paris, the *bourse* is conducted on a very similar plan. There are 60 *agents de change*, 60 *courtiers de commerce*, and 8 *courtiers d'assurance*, who together make up the *parquet*, answering to the board of brokers. The *coulisse* answers to our "street." The time transactions are usually "the end of the current month," or the end of the next month. The 4th of each month is settling day. There is a class of transactions called "free or premium sales," in which the purchaser has the right on the 16th or 30th of

the month to annul his contract by the payment of a small fixed sum. If he adheres to his bargain, when called upon on these days, it is then called *ferme*, "fixed." The *parquet* is in session from 1 to 3 P. M. every day; the *coulisse* is in session then, as well as before and after. The transactions of the latter are as irregular as those of our "curbstone brokers," and its premiums for annulling a sale are less than those of the *parquet*. The stock exchange at London has very similar rules, and its street operators are similar in character.—The excitement at the hour of "high change," in London, Paris, or New York, is often such as beggars description; several hundred men are shouting, calling out what they have to sell or what they wish to buy, at the top of their voices, all together, and leaping and gesticulating, almost as if insane; in speculative periods, immense sums are made or lost in a few minutes. Nathan Mayer Rothschild, the day after the battle of Waterloo, made, it is said, over £1,000,000 sterling in the purchase of stocks.

STOCK FISH. See COD.

STOCK JOBBING. See STOCK EXCHANGE.

STOCKBRIDGE, a township of Berkshire co., Mass., on the Housatonic river and railroad, 168 m. by railroad from Boston, and 17 m. from Pittsfield; pop. in 1860, 2,000. The surface of the township is varied; in the S. is Monument mountain, separating it from Great Barrington, in the W. West Stockbridge mountain, in the S. E. the Beartown mountains, and in the N. W. Rattlesnake mountain. Between these are valleys of great beauty. The Housatonic and its affluents drain the town. The Stockbridge or Housatonic Indians, among whom John Sergeant and Jonathan Edwards labored as missionaries, formerly had their home here, but removed westward in 1788. There are two manufacturing villages in the township, Glendale and Curtisville, where woollen goods to the amount of \$200,000 annually are made, as well as some castings, hollow ware, &c. The village of Stockbridge has a bank, an insurance office, an incorporated academy, several private schools, and 8 churches (Congregational, Episcopal, and Roman Catholic).

STÖCKHARDT, JULIUS ADOLPH, a German writer and lecturer upon chemistry and agriculture, born at Röhrsdorf, near Meissen, Saxony, Jan. 4, 1809. After receiving a classical education he studied practical pharmacy and the natural sciences for several years, and in 1833 was graduated by the board of government examiners at Berlin as an apothecary of the first class. In 1834 he travelled in Belgium, England, and France, and on his return entered as assistant the laboratory of Dr. Struve's pharmaceutical establishment in Dresden. In 1838, having received the degree of Ph.D. from the university of Leipzig, he became teacher of natural science in Blochmann's institute in Dresden, and in the following year teacher of chemistry, physics, and mineralogy in the

technological school at Chemnitz, and royal inspector of apothecaries. His rare talent for presenting, both in the recitation and lecture room, scientific knowledge upon subjects which are usually exceedingly obscure to the community at large, was soon recognized both by the students and the citizens, and the remarkable power of critical observation displayed in his writings (*Untersuchung der Zeickauer Steinkohle*, 1840; *Ueber Erkennung und Anwendung der Giftfarbe*, 1844, &c.) was the occasion of almost innumerable applications for the investigation of commercial problems, and demands for his opinion upon scientific legal questions. In 1848 he travelled in Belgium and France to perfect himself in technological science, and in 1846 published his *Schule der Chemie*. In Germany new editions of this work have been published almost every year since its origin; and it has been translated into at least 8 different languages. It was translated into English by O. H. Peirce, M.D., under the title of "The Principles of Chemistry illustrated by Simple Experiments" (Cambridge, Mass., 1850). In 1844 Stöckhardt began a course of popular agricultural lectures before the Chemnitz agricultural society. The interest excited by these lectures led to the establishment of the system of agricultural experimental stations (*Landwirtschaftliche Versuchs-Stationen*), the importance of the influence exerted by which, throughout Germany, in diffusing scientific knowledge, and in bringing it to bear immediately upon the affairs of practical life, can hardly be overrated. From 1846 to 1849 Stöckhardt edited (with Dr. Hulse) the *Polytechnisches Centralblatt*, and from 1850 to 1855 (with Schober) the *Zeitschrift für Deutsche Landwirtschaft*. In 1848 he was appointed professor of agricultural chemistry in the royal academy at Tharand, a new chair having been founded purposely for him; and he still holds that position (1862). Since then, extending his idea of popular agricultural instruction, he has given, chiefly at his own expense, plain conversational lectures (*Feldpredigten*) in the various farmers' clubs and societies of Saxony and other parts of Germany, explaining the improvements in agriculture which chemical science has shown to be desirable, and illustrating these with experiments whenever this could be done. Several of the more important portions of these lectures have been published in a popular form by their author, as his *Guanobüchlein* (1851; 4th ed., 1856), and *Chemische Feldpredigten* (1851; 4th ed., 1857), both of which have been translated into several foreign languages; and of the latter several English editions exist, as "Chemical Field Lectures for Agriculturists," translated by J. E. Teschemacher (Cambridge, Mass., 1858), and "Agricultural Chemistry, or Chemical Field Lectures" (London, 1855). In 1855 he established at Leipsic a popular journal, *Der chemische Ackeremann*, in which his so called field sermons have since been published; and he

has also contributed to various kindred publications. In 1851 he travelled through the farming districts of England, Scotland, France, and Belgium, and in 1856 through Holland and Belgium. It is said that, principally through his efforts, two bushels of grain are now harvested in Saxony where formerly but one grew.

STOCKHOLM, the capital and largest city of Sweden, in lat. 59° 20' 31" N., long. 17° 54' E., 330 m. N. E. from Copenhagen, and 440 m. W. S. W. from St. Petersburg; pop. in 1861, 136,972. It is beautifully situated at the junction of Lake Mælar with an arm of the Baltic called the Skærgård, the latter being more properly an archipelago indented as it were into the land. The city is built chiefly upon a number of islands, and consists of three principal divisions: the *Stad*, or original city, the *Norrmalm* (northern suburb), and *Södermalm* (southern suburb). It is handsomely designed and built, with several squares and public walks ornamented with trees and statues. The surrounding country, and much of the ground upon which the city stands, are rocky and solid; yet it has been necessary, from the nature of other parts, to build much upon piles, whence the name is derived, meaning island of piles. The city has been likened to Venice, and there are several points of view which recall the southern city of the sea; but the resemblance is imperfect. The approaches by water are uncommonly beautiful, both on the lake side and from the Baltic, commanding views probably unsurpassed of their kind. The most striking object from every point is the great rectangular palace, an immense structure, standing upon an eminence in the central island. Its vast and massive walls rise far above all the neighboring buildings, and its long straight lines need the relief afforded by the towers of the neighboring cathedral church. The palace, of Italian architecture, is a regular quadrangle, flanked upon the E. and W. sides by handsome parallel wings. There are few cities in Europe whose general aspect is more attractive than that of Stockholm. There are vast ranges of buildings, relieved and overshadowed in the Stad by the majestic palace and church towers rising from their midst, in the Norrmalm laid out with modern symmetry and elegance, and in the Södermalm rising from the harbor terraced upon a noble amphitheatre of rocky cliff, and all or nearly all reflected in the clear waves of lake and fiord. From the corner of almost every street debouching upon the wide water fronts, the eye encounters the richest and most remarkable pictures. Nowhere has nature disposed her undulations of soil and curves of water boundary with more endless variety; and nowhere does she produce effects and perspective of more striking beauty. In the compass of a single evening walk one may pass through sombre forest and smooth pasture slopes, climb tall granite cliffs overhanging glassy lake and bay, and glide through the busy seaport filled with sails and moving industry,

the granite quays lined and adorned with architectural beauty, with statues and monuments of art. The various subdivisions of the city, intersected by the waters of the lake and by the sinuosities of the sea, are chiefly islands connected by bridges, some of which are of superb granite masonry. Picturesque ferry boats, propelled by Dalecarlian women in their showy provincial costume, add greatly to the originality of the scene in summer. In winter the waters are compact plains of snow-clad ice, covered with all the moving activity of thoroughfares.—The whole city is contained within a circumference of about 16 miles; but the great park, about $2\frac{1}{2}$ miles in circumference and occupying an entire island nearly opposite the Stad, is not comprised within this area. It is probably the most beautiful public resort in the world. There are over 25 churches; and one of the most interesting objects in the town is the Riddarholm church, containing the tombs and trophies of many heroic personages, and among them those of Gustavus Adolphus, Charles XII., and Charles XIV. (Bernadotte). The houses of the city, about 5,500 in number, are large and convenient, usually 4 stories high, and occupied by families living independently in flats or *étages*; they are generally of brick stuccoed, and colored usually of uniform buff or yellow. Their aspect is cheerful and agreeable, but undistinguished by architectural elegance. In the principal streets, especially in the Norrmalm, there are a few elegant shops; but this species of luxury is still almost in its infancy in Stockholm. In the Norrmalm, the fashionable quarter, are the residences of the wealthy classes and of the nobility. Here the streets are wider and straighter than in most European capitals of the second class. It is so also in the Södermalm, which is the site of the principal factories. In the Stad, on the contrary, the commercial quarter, the streets, with 2 or 3 exceptions, are crooked, narrow, and dark. The city generally is sheltered from high winds. The air is pure and healthy, and the climate in all respects preferable to that of St. Petersburg. The mean annual temperature of Stockholm is 42° F., and the mean temperature of 6 winter months has been observed at 29.4° F. The harbor is one of the finest in the world, and the largest sized ships may penetrate into the very heart of the city.—As the seat of government and residence of the king, Stockholm is the central point of Swedish public affairs, of diplomacy, of several academies of belles-lettres, science, and the arts, of elegant society, and of a great number of institutions useful and charitable. There are several fine theatres and other public places of amusement. The city government is confided to a governor, lieutenant-governor, and a municipal corps composed of 8 burgomasters and 19 councillors. A strong military garrison of lifeguards is always quartered in the handsome barracks built by Charles XIV.; and there is also a burgher guard always on duty. A naval squadron, chiefly of

gun boats, is stationed at an island opposite the palace, called Skeppsholm (ship island). The city, covered by a strong fortress in the neighborhood (Waxholm), is perhaps impregnable by water. By land it is quite without defensive works.—Stockholm is the chief seat of Swedish manufactures, which are here extensive, and include woollen, linen, cotton, and silk fabrics, iron ware, leather, earthenware, tobacco, refined sugar, soap, &c. Iron is the principal article of export, amounting in 1857 to 49,461 tons, in 1858 to 34,984, and in 1859 to 45,162. The other chief exports are tar, planks and boards, and copper. The imports consist principally of cotton and cotton yarn, coffee, grain, rice, hides, tobacco, wool, sugar, salt, coal, breadstuffs, and spirits. The imports of coffee in 1856 amounted to 6,087,741 lbs., of tobacco to 2,076,870 lbs., of sugar to 11,553,425 lbs., and of hides to 1,970,588 lbs. In the same year 217,026 barrels of breadstuffs were imported, and 185,817 barrels exported. The total imports in 1856 amounted to about \$9,000,000, and the exports to \$3,000,000. The following is compiled from the official Swedish reports of tonnage owned in Stockholm:

Years.	Vessels.	Tonnage.	Crews.
1795.....	919	39,092	2,386
1820.....	928	34,558	2,380
1840.....	150	26,048	1,160
1850.....	118	22,264	1,228
1853.....	117	23,716	1,141
1856.....	147	23,263	1,368

—The foundation of the town of Stockholm has been ascribed to Birger Jarl, the father and guardian of Waldemar, elected king in 1250. A settlement had been in existence at the spot, however, since the destruction of Sigtuna by Finnish pirates in 1187. At this epoch the island upon which the modern palace stands was originally fortified with walls and towers of wood, and the pirates were kept in check by works which thus defended 7 towns which stood on the banks of the lake. The strength of its fortifications subsequently exposed the city to repeated sieges. It became the residence of the Swedish monarchs soon after Birger's death, but Upsal continued long afterward to be the seat of government. With Lübeck and Hamburg reciprocity of free trade was established; and similar relations with Riga soon followed. Birger also sought to form commercial relations with England. On two memorable occasions Stockholm was defended by women—"Shakespearian women," as a Swedish historian aptly terms them. In 1501 the citadel was held against insurgents by Christina, queen of Denmark, whose husband, King John, ruled over the 3 united kingdoms of Scandinavia. King John had left his queen in command of a garrison of 1,000 men, whose number, after a siege of 5 successive months, was reduced by famine and the sword to 80. She was compelled to capitulate. A still more heroic defence was that originated and conducted by Christina Gyllenstierna, the widow

of the fallen regent Stan Sture. The besiegers were Danes, under Christian II. After a terrible siege of 4 months, the place was surrendered with the most solemn guaranty of the king to respect the rights of the inhabitants. A most fearful massacre ensued, known as the "blood bath of Stockholm."

STOCKING, a covering of some textile fabric closely fitted to the foot and leg. The word is said to be derived from the Saxon *stican* (past participle, *stocken*), to stick, because the material was stuck, or made with sticking pins, now called knitting needles. In the 15th century the whole dress below the waist was made in one in England, and was called hose. In the next century, possibly somewhat earlier, it appears to have been first divided into breeches and stockings, which last also retained the original name. Stockings are said to have been made first of cloth in England; and such, Howell states, in his "History of the World," Henry VIII. ordinarily wore, "except there came from Spain, by great chance, a pair of silk stockings. K. Edward, his son, was presented with a pair of long Spanish silk stockings by Thomas Gresham, his merchant, and the present was taken much notice of. Queen Elizabeth was presented by Mrs. Montague, her silk woman, with a pair of black knit silk stockings, and thenceforth she never wore cloth any more." On the continent stockings were made much earlier than in England; and in 1527 there existed in France, as stated by Beckmann, a stocking knitters' guild. Nothing is known of the origin of knitting, or with certainty when it was introduced into England. It was practiced there in the reign of Queen Elizabeth, and stockings were knit of worsted as well as of silk. A machine called the stocking frame for weaving them was invented in 1589 by William Lee, a student expelled from St. John's college, Cambridge, for marrying against the rules of the college, and who was thus rendered dependent upon the labor of his wife in knitting stockings. Failing of encouragement at home, he took the machine to France. After his death there his workmen brought back the invention to England, and introduced the manufacture in London and its vicinity. It was afterward established in Nottinghamshire, which has ever since been famous for its production of stockings. When Sir Richard Arkwright introduced cotton spinning at Nottingham, the first product, made of two roves instead of one, and called double spun twist, was found from its evenness so well adapted for the stocking manufacture, that it was all devoted to this purpose; hand-spun cotton was entirely laid aside, and stockings made of twist soon supplanted those of thread. It was on Lee's stocking frame that the first machine-made lace was produced in the last century, and it formed the basis of those now used in this manufacture. In 1756 an improvement was added in Derby to the machine, fitting it for making ribbed stockings like those produced by knitting, and

these are still known as the "Derby ribs." The old frame, however, still continued a clumsy and complicated machine, workable only by hand; and all attempts to adapt it to power, though many were made at great cost, were abandoned in England as hopeless, until this had been successfully accomplished in the United States, as will be noticed below. The stocking manufacture is now carried on to a vast extent in the counties of Nottingham, Leicester, and Derby, England, and to a less degree in some towns in Scotland. Hawick, in Roxburghshire, produces annually between 1,500,000 and 2,000,000 pairs. The business has been greatly improved since 1844, and an immense change has of late taken place in the cheapness of the goods, so that they are introduced where stockings were before unknown. With the old hand frames a workman made in a week about a dozen cotton hose, weighing 2 lbs. The same labor now applied to a set of the power rotary round frames easily produces in the same time 200 dozen, consuming 300 lbs. of cotton, which sell at 2s. 6d. per dozen. The total number of stocking frames in Great Britain is estimated at about 50,000, of which at least 17,250, worth £810,000, are in Nottinghamshire, giving employment to about 40,000 persons in the various operations of making, stitching, sewing, finishing, &c. Those in Leicestershire give employment to about 35,000 persons. The materials used are woollen yarns, lamb's wool, cotton, silk, and mixed cotton and wool or angola.—Stocking frames were introduced into the United States in the 18th century at several places where the cotton manufacture was prosecuted. German emigrants established the knitting business at Philadelphia and Germantown, Penn., and English emigrants from Nottinghamshire introduced it into New York city and several places in the middle and eastern states. The adaptation of the old Lee machine to power was first accomplished by the ingenuity of Timothy Bailey in Albany in 1881; and the first machine thus run was at Cohoes, N. Y., in Oct. 1882. At this place the manufacture of hosiery has since become a very important branch of industry, but with machines of much more perfect construction. The old Lee invention was a square frame, which produced a straight strip or flat web, which was cut off in proper lengths, and seamed together to form the stocking. But a great improvement upon this, the origin of which is unknown, was the circular loom in which a continuous circular web is knit of any length, and which is cut up and formed by different methods into the shape of a stocking. It is believed that the first of these introduced into America was brought from Belgium into Connecticut by a German, about the year 1885. Several others of different construction have since been devised in the United States for manufacturing purposes, and a few intended also for family use.—The various knitting machines, which are too numerous to be men-

tioned in detail in this article, produce what is called the stocking stitch or chain work, the same as in common hand-knitting with two or more needles, or in crocheting, which consists of loops formed in succession upon a single thread, each one locked by that which follows it. The fastening of the end finally secures the whole and prevents its ravelling. These machines may be distinguished by the different kinds of needles they employ, and also by the manner in which these are arranged—whether on a straight horizontal line, all pointing the same way, as in the common stocking loom, or around an open horizontal circle, all pointing toward the centre. The latter are known as the rotary round machines. All the needles are hooked at the end, so as to hold the thread laid across it that is to form the next loop, while the loop previously formed on the same needle slips back on the shank as the needle is pushed forward, and with its return runs over the hook and off the end. The contrivance by which this is effected distinguishes the several needles. In the spring or bearded needle used in the original stocking frames, and still in common use, the hook is drawn out to considerable length and is made elastic, so that when its point is pressed down into the groove upon its shank it may spring up when the pressure is removed. In the machines this pressure is applied by means of a wheel bearing down upon the beard of the hook for an instant with the production of every loop. A very efficient rotary round machine using this needle, and introduced in many of the factories of the United States, is that invented by Mr. Goff of Seneca Falls, N. Y. A second needle is that used in the McNary patent seamless hosiery machine. It is a short slender needle with a groove upon the top of the shank, in which works a tongue distinct from the needle. This is a rotary round machine, and is distinguished for producing the whole stocking without seam. The stocking was patented in 1856, the machine in 1860, and improvements in 1861. The capacity of each machine is to produce from 2 to 3 dozen pairs of half hose per day, and one female operator of ordinary skill will tend 3 or 4 machines. Another needle is known as the latch needle, and this is used in the machines of Mr. J. B. Aiken, of Franklin, N. H. It has a very short hook, and is provided with a little tongue or latch working upon a pivot in the shank, so as to close down upon the point of the hook and thus allow the loop to run over it. The latch works back and forth as it is pushed by the loop when the needle moves first forward and then back. The first movement, sending the loop on to the shank from the hook, first throws back the latch for the loop to slide over it, and the next closes the latch upon the point of the hook, allowing the loop to run off the end of the needle. In the working of the machine, the thread while the latch is open is laid across the needle in the hook; and when

the previous loop is slipped off, this serves as a new one to support the work. This consequently hangs upon the needles by a single loop upon each one. The thread as the operation goes on is rapidly carried to each needle in turn, and the movement is instantly produced that adds a new loop and slips off the old one. In the straight frames the work is done first across the needles in turn in one direction and then back in the other, and so on; but in the rotary round machines the revolution carries the needles constantly round in the same direction, each one taking up the thread in turn, and so rapidly that the movements cannot be clearly perceived. The one class of machines produces a flat web, and the other a cylindrical or tubular one, each of which hangs from the needles and is drawn down as it increases in length, by means when necessary of a weight attached to it. The number of stitches or loops which each machine can form in a minute varies with the gauge of the needles or the distance apart at which they are set. The machine of Mr. Aiken for ordinary stockings, containing 92 horizontal needles and run by power in the factories, may make from 100 to 200 revolutions per minute, producing the same number of stitches to each needle, thus amounting to 9,200 to 18,400 stitches per minute. The machines constructed for family use, and worked by a treadle or crank like a sewing machine, make about half as many stitches as the factory machines. In the factory 3 or 4 machines are easily tended by one boy. Ribbed work is performed in the same machines by bringing in play a set of vertical needles, so arranged as to work in connection with the horizontal and produce the additional stitches required. As the needles are set to a particular gauge, they necessarily produce the same number of stitches to the inch; and the only variations practicable in the work are in using yarns or threads of different degrees of fineness, and in altering the tension so as to make the work closer or more open. In the stocking frames this is of no great importance; but in the various kinds of fancy work, subject to the fluctuations of fashion, the machines adapted for special patterns may be suddenly rendered almost worthless by the demand for those patterns ceasing.—The shaping of the web to fit the foot is a matter of no little ingenuity. The flat web is either knit in long strips of sufficient width to make when turned over several stockings which are cut out from these; or the web is at once knit upon the machine in the shape required for making a stocking when the parts are properly folded over. The former is known as out work, and the latter as regular work. In the latter the wider part, when turned over and fastened, either by lapping and sewing with the sewing machine, or by seaming with a needle and thread, forms the leg of the stocking. Two narrow strips at the base of this part, turned under and joined together upon the machine

or by other means, form the heel; while a central strip twice the length of the foot, being turned over at the toe, forms the top and bottom of the foot, and is neatly united to the heel and around its edges by knitting or seaming. The cutting and fitting of the broad webs cannot be intelligibly described without the aid of drawings. In forming the foot to the circular webs after these are cut off in suitable lengths, a slit is made above the heel half across the web, which admits of the part designed for the foot being curved out at the instep. The loops along the edges of the cut are then taken up on hand needles, and the space for the heel is filled out by hand knitting, the edges being carefully united. In the same manner the toe is completed; and thus the stocking is finished without a seam. An important machine was very recently invented by Mr. Leslie of Brooklyn, N. Y., which accomplishes what has never been done before upon rotary round machines—the narrowing of the work in any manner desired.—Notwithstanding the large number of machines employed in knitting, stockings are still largely produced by the old method of hand knitting, which admits of the use of a harder and firmer yarn than that adapted to the machines; and even where the machine work is produced in large mills employing steam power, the hand looms are also in extensive use, many of them in the houses of the operatives, who work at their own hours and at their own convenience. In the factories the knitting machines are also made to produce many other articles of apparel, as undershirts, drawers, comforters, scarfs, opera hoods, talmas, nubias, gloves, mits, &c. One factory in Philadelphia, that of Martin Landenberger, employs about 500 hands, and consumes annually more than 250,000 lbs. of American wool. The total operations in Philadelphia for the year 1857 have been estimated as follows:

500 knitting frames averaging \$1,657.50	\$828,750
7 factories in Germantown and Kensington.....	900,000
Total value of woollen hosiery	\$1,628,750
200 knitting frames on cotton hosiery, \$897 each..	179,400
Total.....	\$1,808,150

The other principal establishments in the United States are the factories in Cohoes, Troy, and Seneca Falls, N. Y., Paterson, N. J., and the Brooklyn knitting works, Brooklyn, N. Y.

STOCKPORT, a manufacturing and market town and parliamentary borough of Cheshire, England, at the junction of the Mersey and the Thame, 5 m. S. E. from Manchester; pop. in 1861, 54,681. It stands upon a hill, and the houses rise above each other in irregular tiers. The river is crossed by 4 bridges, and there are several suburbs, the most extensive of which are Heaton-Norris, Edgeley, and Portwood. The principal public buildings are the barracks, court house, union workhouse, and the building for the Sunday school, which is attended by nearly 4,000 children. In former times the manufacture of silk was extensively carried on here; but lat-

terly it has been supplanted by that of cotton, for the spinning and weaving of which there are in the town and suburbs about 100 factories, employing nearly 4,000 horse power. One of these buildings is 800 feet long, 200 feet broad, and 6 stories high, and has 100 windows in each story. There are also several establishments for bleaching, dyeing, and printing cotton, brass and iron foundries, &c. Rich coal mines are worked in the vicinity, and great facilities are given to trade by the Manchester and Ashton canal, and by several lines of railway which have their junction at Stockport.—The town is believed to occupy the site of an old Roman station. Stockport castle, which has now disappeared, was held against Henry II. in 1178 by Geoffrey de Constantin. During the civil wars the town was garrisoned by parliamentary troops, was taken by Rupert in 1644, and retaken by Lesley the next year. It was occupied by Prince Charles Edward in 1745.

STOCKS, a wooden machine once universally employed in England for confining unruly persons by the feet or hands, and sometimes by both. It has long gone out of use, but is still to be seen in secluded rural districts.

STOCKS. See **STOCK EXCHANGE**.

STOCKTON, a town, port of entry, and capital of San Joaquin co., Cal., situated on a channel of its own name, near the San Joaquin river, and 130 m. E. S. E. from San Francisco; pop. in 1860, 3,679. It is an important commercial point, vessels of 400 tons being able to navigate the channel. It is on the main road from Los Angeles to Sacramento, and is the chief point of trade with the southern gold mines. It has 3 newspapers, several churches, and a hospital.

STOCKTON, RICHARD, an American statesman, and a signer of the declaration of independence, born near Princeton, N. J., Oct. 1, 1780, died there, Feb. 28, 1781. He was graduated at the college of New Jersey, at Newark, in 1748, studied law, was admitted to the bar in 1754, and rose rapidly to the first rank as a lawyer. In 1766 he visited England. He was made a member of the executive council of New Jersey in 1768, and in 1774 appointed a judge of the supreme court. In 1776 he was elected to congress, and, though at first doubtful of its policy, cordially supported the declaration of independence. In the same year he served on the committee appointed to inspect the northern army and report its state to congress, and after his return to New Jersey was captured by the British and confined in the common prison at New York. The unusual severity with which he was here treated broke down his strength, and eventually caused his death.—**ROBERT FIELD**, an officer of the U. S. navy, grandson of the preceding, born in Princeton, N. J., in 1796. In his 15th year, while a student in Princeton college, he entered the navy as midshipman, became an aid to Commodore Rodgers on board the frigate President, receiving honorable notice for his gallantry in several bat-

ties, and in Dec. 1814, was promoted to a junior lieutenant. In 1815 he was sent to the Mediterranean in the *Guerrière* in the war against Algiers, but was soon transferred to the *Spitfire* as first lieutenant, in which he distinguished himself by boarding with a boat's crew an Algerine war vessel. In Feb. 1816, he was ordered to the *Washington*, 74, the flag ship of Com. Chauncey, cruising in the Mediterranean, and subsequently transferred to the *Erie*. In 1821 he was sent to the United States in command of the *Erie*, and was then ordered to the coast of Africa, with permission to aid the colonization society in procuring a new site for its settlement. Accompanied by Dr. Ayres, the agent of the society, he succeeded with some difficulty in obtaining from the native chiefs a treaty ceding a tract of land around Cape Mesurado, which was the original territory of the present republic of Liberia. During his cruise on the African coast, Lieut. Stockton captured a considerable number of slavers, and a Portuguese privateer, the *Marianna Flora*, of 22 guns, which had attacked him. This vessel he sent to the United States, and a series of trials followed in the United States courts as to the propriety of her capture. Lieut. Stockton was finally justified in the supreme court, but the vessel was given up to Portugal as an act of comity. He also captured a French slaver, which led to litigation, but was again justified by the court. On his return from the African coast he was ordered to the West Indies to break up the nests of pirates preying upon our commerce, in which enterprise he was successful. In 1826-'88 he was for a considerable time absent on leave from the navy, at his home in Princeton, taking an active part in politics in favor of Gen. Jackson, and also in the promotion of internal improvements in the state. In 1888 he was sent to the Mediterranean as flag officer of the *Ohio*, Com. Hull's flag ship, and in 1889 promoted to a post-captaincy and recalled. He had for some years given much attention to gunnery, the construction of steam engines, and naval architecture, and obtained permission from the navy department to construct a war steamer after much solicitation, the previous attempts of the department having proved failures. Capt. Stockton's plans were new, and embraced designs which the naval constructors confidently pronounced impracticable; but the steam sloop of war *Princeton*, commenced at Philadelphia in 1842, and completed in 1844, proved to be superior to any war vessel at that time afloat, and has furnished substantially the model for numerous others, not only in the United States, but in England and France. Her speed and sailing qualities, her admirable model, the security of her motive power, which for the first time was placed below the water line, and her powerful armament, all attracted attention. She carried 2 225-lb. wrought iron guns, made under the supervision of Capt. Stockton, beside 12 42-lb. carronades. The

unaccountable explosion of one of these large guns, at Washington, Feb. 28, 1844, led to the death of 5 distinguished men, among them the secretaries of war and the navy, and seriously injured Capt. Stockton himself. The naval court of inquiry which investigated the case, completely exonerated him from all blame or want of precaution either in the construction or firing of the gun. In Oct. 1845, he was sent with a reinforcement to the squadron on the Pacific coast, in the command of which he succeeded Com. Sloat soon after his arrival at Monterey, California. Here he was placed in circumstances which in his opinion required prompt and decisive action, while communication with his government was impossible. With a force of not over 1,500 men in all, of whom about 600 were sailors from the ships of the squadron, and the remainder mostly Californian settlers, in about 6 months he conquered the whole of California, and established the United States authority there. The collision between him and Brig. Gen. Kearny in relation to the right to the supreme command there, was subsequently made the subject of a court martial. Having established a provisional government, he returned to the east, overland, in June, 1847. In 1849 he resigned his commission in the navy, and in 1851 was elected to the U. S. senate, where he strenuously opposed the project of intervening in favor of Hungary and against Austria, as desired by Kossuth, and procured the passage of a law for the abolition of flogging in the navy. In 1853 he resigned his seat in the senate, and has since held no public position.

STOCKTON, THOMAS HEWLINGS, D.D., an American clergyman, born at Mount Holly, N. J., June 4, 1808. He began to write for the press at the age of 16, and studied medicine in Philadelphia, but in May, 1829, commenced preaching, in connection with the Methodist Protestant church. In 1830 he was stationed at Baltimore, and in 1833 was elected chaplain to congress, and reelected in 1835. From 1836 to 1838 he resided in Baltimore, and in addition to pastoral duties compiled the hymn book of the Methodist Protestant church, and was for a short time editor of the church newspaper, "*The Methodist Protestant*;" but, unwilling to submit to restrictions sought to be imposed upon him in its discussion of slavery by the Baltimore conference, he soon resigned and removed to Philadelphia, where he remained till 1847 as pastor and public lecturer. He then removed to Cincinnati, and while residing there was elected president of Miami university, but declined, and in 1850 returned to Baltimore, where he was for 5 years associate pastor of St. John's Methodist church, and for 3½ years temporary pastor of an Associate Reformed Presbyterian church. Since 1856 he has resided in Philadelphia. He was again chaplain of the U. S. house of representatives from 1859 to 1861, and is now (1862) chaplain of the senate. Dr. Stockton has edited several

different periodicals, and published an edition of the New Testament in paragraph form, and, beside numerous pamphlets, sermons, and occasional addresses, the following works: "Floating Flowers from a Hidden Brook" (Philadelphia, 1844); "The Bible Alliance" (Cincinnati, 1850); "Sermons for the People" (Pittsburg, 1854); "The Blessing" (Philadelphia, 1857); "Stand up for Jesus" (1858); "Poems, with Autobiographic and other Notes" (1861); and "The Peerless Magnificence of the Word of God" (1862).

STODDARD, a S. E. co. of Missouri, bordering on Arkansas, and bounded W. by the St. Francis and E. by the Castor and White-water rivers; area, 900 sq. m.; pop. in 1860, 7,877, of whom 215 were slaves. The greater portion of the county is level, and there are a number of swamps and shallow lakes, the principal of the latter being Lake Nicormy, 25 m. long and 4 m. wide. It is a part of the "sunk country" produced by the earthquake of 1811. (See EARTHQUAKE, vol. vi. p. 722.) Large forests of cypress abound. The productions in 1860 were 151,094 bushels of Indian corn, 17,260 of oats, 5,972 of wheat, and 38,174 lbs. of butter. Capital, Bloomfield.

STODDARD, RICHARD HENRY, an American poet and author, born in Hingham, Mass., in July, 1825. His father, a sea captain, was lost on a voyage to Sweden in the early youth of the son, who for several years worked in an iron foundry in New York. His health failing in consequence, he became in 1848 a contributor to the magazines and newspapers. In 1849 he published a volume of poems under the title of "Footprints," followed in 1852 by a maturer collection. About the same time he was married and received an appointment in the New York custom house, which he still holds (1862). His remaining publications comprise "Adventures in Fairy Land" (Boston, 1858), a series of prose tales; "Songs of Summer" and "Town and Country, a Book for Children" (1857); and "The Loves and Heroines of the Poets" (New York, 1860). He is still a frequent contributor to the periodical press.

STODDARD, SOLOMON, an American clergyman, born in Boston in 1648, died in Northampton, Mass., Feb. 11, 1729. He was graduated at Harvard college in 1662, was afterward appointed "fellow of the house," and was the first librarian of the college, which office he held from 1667 to 1674. During this time, on account of his health, he accompanied Gov. Serle to Barbados in the capacity of chaplain, and remained there nearly two years, preaching to the dissenters. In 1669 he was called to succeed the Rev. Eleazar Mather as minister of the church at Northampton, and was ordained as such Sept. 11, 1672. In Feb. 1727, Mr. Jonathan Edwards, a grandson of Mr. Stoddard, was elected as his colleague. In 1700 Mr. Stoddard published "The Doctrine of Instituted Churches," as an answer to the work of Increase Mather entitled "The Order of the

Gospel," which occasioned an exciting controversy. He maintained that the sacrament of the Lord's supper is to be regarded as a converting ordinance, and that all baptized persons, not scandalous in life, may lawfully approach the table, though they know themselves to be destitute of true religion. In 1708 and 1709 the same controversy was renewed, and one or two able pamphlets on each side were written. He also published several miscellaneous and occasional sermons; "A Guide to Christ, or the Way of directing Souls in the Way of Conversion, compiled for Young Ministers" (1714); and "The Safety of appearing in the Day of Judgment in the Righteousness of Christ," which was reprinted at Edinburgh in 1792.

STOIOS (Gr. *στωα*, porch), or philosophers of the porch, one of the speculative schools of antiquity, so called from the place in which their founder Zeno gave his instructions. Of their earlier representatives, the most prominent were Zeno (about 800 B. C.), Ariston, Cleanthes, Chrysippus, Zeno of Tarsus, Diogenes of Babylon, Antipater, Panætius of Rhodes, and Posidonius (probably 135-51 B. C.); of their later, Seneca (died A. D. 65), Epictetus, Marcus Antoninus, Arrian, and many of the most distinguished Roman citizens. Originally treating the three departments of logic, physics, and ethics, they are chiefly known as moralists, since they connected philosophy intimately with the duties of practical life, and taught the most complete of pagan ethical systems. In logic, they found the criterion of knowledge in sensuous impressions, which furnish the materials fashioned by reason, and combated scepticism, like the modern Scottish school, by affirming that every representation of an object implies the existence of the object itself. In physics, they inclined to pantheism, regarding God and the world as power and its manifestation, matter being a passive ground in which dwells the divine energy. But though they conceived of the Deity as the controlling reason of the universe, the earlier of them sought a material expression for this conception, and spoke of him either as a rational breath or an artistic fire. Their ethics was a protest against growing moral indifference, and had in it something of the excess of a reaction. Their aim was to transfer the theory of nature, ruled by reason, to human life. To live in harmony with nature, conformably to reason, was their fundamental maxim. Reason is impersonal, universal; hence pleasure, whose ends are individual, must be disregarded; the passions, which are not rational impulses, are to be extirpated; and a state of apathy is to be cherished, which secures liberty, the prize and quality of virtue. To be free is to act by universal reason, looking only to universal good, disengaged from anger, jealousy, envy, and hatred, and with entire self-abnegation. Thus life is rendered always uniform and equal to itself. The sage is like a good actor, who, whether he take the part of Agamemnon or of

Thersites, does it equally well. And as the divine reason is the law of virtue, every virtuous act is an act of piety; and as all things are well done in the city of God, the wise man will resign himself complacently to events. Thus there is no good but virtue, or obedience to reason, and no evil but vice. Pleasure, pain, health, wealth, life, and death are matters of indifference. Virtue depends exclusively on ourselves, and no one can take it from us; but all things else depend on others or on fortune, and the sage should be independent of them. But even the stoical apathy admitted the promptings of the heart as the impulse of nature; it did not, as Plutarch says, wish to transform men into Lapithæ of bronze and diamond; it allowed a choice in indifferent things, so far as they might enter into the account of a moral life; but it laid its stress on the inner light of duty, on resignation, piety, and tolerance. While it introduced a clear conception of absolute right, founded on universal order and harmony, it failed to furnish a system of concrete duties. Its ideal of man was a divinity without earthly relations. The asylum of heroic moralists, it exerted a private and speculative but no political influence, and regenerated nothing in Greek society. More congenial to the genius of the Romans, it became among them an ardent faith, the religion of great souls, having its devotees and martyrs, and furnished to the empire its best rulers. During the period of decline, it disputed with Epicureanism for the supremacy. The one taught love of self, voluptuous repose, intellectual relaxation, moral suicide; the other, dwelling in the sanctuary of conscience, taught love of virtue, tended to concentration and force, killed the passions. The apathy of the one proceeded from a soft abandonment to circumstances; that of the other, from an earnest effort to save the dignity of man when all the interests of society seemed to be making shipwreck. The one had no higher view than pleasure; the other, in a falling empire, conceived of a universal republic, and of law as the queen of mortals and immortals, generalized the conditions of sympathy, and proclaimed beneficence a virtue equal to justice. The stoical and Christian ethical systems have often been compared. *Stoici nostro dogmati in plerisque concordant*, said St. Jerome. Others of the church fathers spoke of Seneca as *Seneca pene noster*. Montesquieu said that, if he could for a moment forget that he was a Christian, he would not hesitate to account the extinction of the sect of Zeno among the misfortunes of mankind. Yet the two systems belong to entirely different schemes and tempers of thought, and cannot be compared in detail. There is a more direct antagonism between stoicism and utilitarianism. Bentham, after stating the doctrine that pain is no evil, and that virtue of itself is sufficient to confer happiness, adds: "This was the sort of trash which a set of men used to amuse themselves

with talking, while parading backward and forward in colonnades, called porches."—See Ravaisson, *Essai sur la métaphysique d'Aristote*, vol. ii. (1887); Tiedemann, *System der stoischen Moral* (1776); and Meyer and Klippel, *Vergleichung der stoischen und christlichen Moral* (1823).

STOKE-UPON-TRENT, a town and parliamentary borough in Staffordshire, England, the latter including about $\frac{1}{3}$ of what is commonly called the Potteries, and embracing several parishes and townships, among which are Burslem, Lane-End, Longton, Hailey, &c.; pop. of the borough in 1861, 101,803; of the town, 57,942. Stoke is situated on the river Trent, 16 m. N. by W. from Stafford, and 148 m. N. W. from London. It has very extensive manufactures of china and earthenware. The borough returns two members to parliament.

STOKES, a N. co. of North Carolina, bordering on Virginia, and drained by a branch of the Dan river; area, 550 sq. m.; pop. in 1860, 10,402, of whom 2,469 were slaves. The surface is hilly and the soil fertile. The productions in 1860 were 16,004 bushels of wheat, 228,000 of Indian corn, and 42,636 of oats. There were 6 iron forges, 19 tobacco manufactories, and 1,085 pupils attending public schools. Iron ore is abundant. Capital, Germantown.

STOLBERG, FRIEDRICH LEOPOLD, count, a German author, born at Bramstedt, Holstein, Nov. 7, 1750, died near Osnabrück, Dec. 5, 1819. At Göttingen, where he completed his studies (1772-'5), he was a leader in the *Dickterbund*, including Boje, Bürger, Miller, Voss, Hölty, and Leisewitz, which acknowledged Klopstock for master. In 1775 he travelled with Klopstock, Goethe, and others through southern Germany and Switzerland; in 1777 was appointed ambassador of the prince-bishop of Lübeck at Copenhagen; fulfilled a diplomatic mission in Russia in 1785; became Danish ambassador at Berlin in 1789; and, on returning from travels in Italy (of which he wrote a narrative, 4 vols., 1794), was placed at the head of the administration of Lübeck in 1791. He had already published a translation of the *Iliad* (1778); a volume of lyrics (1784); the *Schauspiele mit Chören* (1786), in which Theseus and Timoleon are celebrated as founders of civil liberty; and the prose romance *Die Insel* (1788), a Utopian description of a perfect republic. In 1800 he united himself with the Roman Catholic church; and his position as a statesman and scholar lent importance to this event, which appears prominently in the contemporary writings of Voss, Gleim, Jacobi, Herder, Haller, Lavater, and Schiller, and which served as an example to the younger Schlegel and others of the romantic school. His principal subsequent work was the *Geschichte der Religion Jesu Christi* (15 vols., Hamburg, 1811-'18), embracing the period from the creation to A. D. 480. It was continued by Kerz (vols. xvi. to xlvii., Meitz, 1825-'46), to the end of the 12th century, and

by Brischer (vols. xlvii. *et seq.*, Mentz, 1849 *et seq.*). An index to vols. i. to xv. was prepared by Moritz (1835), and to vols. xvi. to xxiii. by Saanen (1834). He also published lives of Alfred the Great (1815) and St. Vincent de Paul (1818). His writings form the larger part of the *Werke der Brüder Stolberg* (22 vols., Hamburg, 1821-'6).—CHRISTIAN, count, a German author, brother of the preceding, born in Hamburg, Oct. 15, 1748, died near Eckernförde, Jan. 18, 1821. He studied at Göttingen (1769-'74), where he was a member of the *Dichterbund*, and wrote poems, translations, and plays.

STOMACH, the hollow organ in which the function of digestion is performed, as uniformly present, in variously modified forms, in every perfectly developed animal, as it is absent in the vegetable kingdom. From the simplest form in the polyp to the complex structure in the ruminant, this organ is described under the appropriate titles, and particularly under **COMPARATIVE ANATOMY**. As a general rule, throughout the vertebrate animals we find a complex stomach associated with a vegetable diet; but this has striking exceptions, as for instance in the dolphin, which has a multiple stomach with an animal diet, and the horse, which has a simple stomach with the same vegetable food as the ox. In man the stomach is the widest and most dilatable part of the alimentary canal; it is situated in the upper part of the abdomen, in the epigastric and part of the left hypochondriac region, below the diaphragm, above the arch of the colon and transverse mesocolon, and to a certain extent between the liver and spleen; it comes in contact in front with the anterior wall of the abdomen, and behind with the organs and vessels lying upon the spine. Its shape varies greatly, but when moderately distended, in or out of the body, resembles a bent cone, curved from before backward and from above downward, following its length; it lies almost transverse, a little obliquely downward, forward, and to the right; the anterior border is the greater curvature, and is lodged between the folds of the great omentum; the œsophagus enters at about $\frac{1}{4}$ of the length from the left extremity; the great *cul-de-sac* on the left is limited to the spleen by short vessels. It is about 14 inches long, and 5 wide at the central part, tapering gradually to the pylorus on the right; its normal capacity is about 175 cubic inches or 5 pints, and its weight 6 to 7 ounces. Though naturally kept in place by the omental folds of the peritoneum, any unusual distention may displace it, chiefly in a downward direction; the habit of tight lacing sometimes gives to the stomach a permanent hour-glass shape, variously thrusting its openings from their natural positions, and greatly embarrassing digestion. The œsophagus or gullet, after passing through the diaphragm, opens into the stomach at the cardiac orifice on the left, and the digestive cavity is separated from the intestinal

canal by an external constriction and an internal valve at the pyloric opening on the right. Its walls consist of 8 coats, an external or serous, middle or muscular, and internal or mucous; the 1st keeps the organ in place, limiting its movements, the 2d enables it to execute the peristaltic movements so necessary to digestion, and the 3d secretes by its glands the gastric and other juices concerned in the preparation of chyme; some anatomists count a 4th or fibrous layer between the muscular and the mucous. Between the coats are layers of areolar tissue, containing the vessels, nerves, and lymphatics; the muscles are of unstriated or organic fibre, arranged in longitudinal, circular, and oblique layers. The mucous membrane is delicate, smooth and velvety in some parts, more or less rugose in others, reddish white, covered with a mucous secretion, and rapidly undergoes disorganization; beside the usual glands noticed under **INTESTINE**, it also contains special gastric cells, whose secretion has been described under **DIGESTION**. The blood vessels are very large and numerous, the arteries coming from the coeliac axis of the abdominal aorta, and the veins emptying into the vena portæ; they freely inosculate in their branches, and are tortuous in their course and loose in their connections to accommodate the distentions of the organ. The nerves are derived from the pneumogastric, and from the solar plexus of the sympathetic system. On the introduction of food into the stomach the organ is excited to movements, the mucous membrane becomes darker and begins to pour out the gastric fluid; the food enters from the œsophagus in successive waves, and is at once subjected to the peristaltic movements which thoroughly mix the gastric juice with its mass; the act of respiration assists in the stomachal movements. The usual course of the food is first to the left of the cardiac orifice, thence along the larger curvature from left to right toward the pylorus, thence returning along the upper or lesser curvature from right to left, to go again through the same course; the revolution takes place in from 1 to 8 minutes, according to the stage of digestion; it is due probably in great measure to the action of the circular muscular fibres. The pylorus is closed during early digestion, gradually relaxing as the process goes on, allowing an almost constant passage of chyme into the duodenum; sometimes the contents pass in the reversed direction, as in vomiting, in which the cardiac orifice is relaxed, the pylorus comparatively closed, and the organ compressed by the abdominal muscles, assisted perhaps by its own contractions. The mucous membrane may be the seat of softening, congestion, hæmorrhage, acute and chronic inflammation, ulceration, and cancerous growths.

STOMACH PUMP. See **SYRINGE**.

STONE, a general term including all solid mineral substances. The subject is treated mineralogically in the article **MINERALOGY**, and

economically under the various names of useful minerals and rocks, as DOLOMITE, GRANITE, MARBLE, PORPHYRY, SANDSTONE, and SLATE. In the present article the adaptation and uses of stone for different structures of importance will be considered. In the remotest periods durable stones were esteemed the most valuable materials for architectural purposes, and more judgment was shown in their selection, than are exercised at the present day. It may even be said that greater skill was possessed by the architects of the most ancient monuments in carving and polishing the hardest stones than has ever since been exhibited. The ancient Egyptians, using no harder tools, that we are aware of, than those of bronze, quarried and dressed huge blocks of granite, and covered them with the most delicate and sharp-cut hieroglyphics, leaving the whole surface highly polished. Their wonderful structures are referred to more particularly in the article PYRAMID; and the use of different stones by other nations of antiquity is incidentally treated in the article ARCHITECTURE. It is remarkable that the ancients, with their imperfect machinery, possessed the power of quarrying and moving masses of stone as large as any moved in modern times. Structures were even hollowed out of single blocks, and transported long distances. Such was that described by Herodotus, which Amasis transported from the isle of Elephantine to Sais, a distance of 20 days' ordinary sailing. It measured outside 27.72 by 18.48 feet, and was 10.56 feet high; within, 24.86 by 15.84, and 6.6 feet high; thus containing 2,822 cubic feet, which probably weighed 458,744 lbs. Another structure of similar character, also described by Herodotus as forming part of the temple of Latona at Buto, is estimated to have weighed 9,944,750 lbs. This enormous mass, it is supposed, was quarried upon the spot where it was placed, as no mention is made of its transportation, and as its movement would seem to be utterly impracticable; but it was covered with a block, which must have been moved and raised above its walls, described as 52.8 feet square and 5.28 feet thick, making 14,720 cubic feet, and a probable weight of 1,984,550 lbs. The largest mass of stone that has been transported in modern times is the pedestal of the statue of Peter the Great at St. Petersburg, which weighs 3,284,000 lbs. It was found impossible in moving it to make use of rollers of wood or iron, and even balls of wrought and cast iron were crushed down under the immense weight; and the last resort was to balls made of an alloy of copper, tin, and zinc. From the drawings preserved of the operations of the ancient Egyptians and Assyrians, it appears that the heavy stones which they employed were drawn by main strength of men, arranged in order along several strong ropes, upon causeways and inclined planes of cut stones specially constructed. Some were placed upon massive

sledges, and drawn upon wooden ways, which were lubricated with some liquid substance, and some were moved by rolling them over. It has been estimated that a force equal to a little over $\frac{1}{2}$ of the weight of a stone is necessary to draw it, when rough, upon a firm and smooth horizontal bottom; $\frac{1}{3}$ of its weight upon a surface of wood, or $\frac{1}{4}$ if upon a wooden support moved upon wood, and if the two surfaces are soaped only $\frac{1}{5}$. The use of rollers upon ground not compressible reduces the required force to about $\frac{1}{10}$ of the weight, to $\frac{1}{15}$ if they roll upon wood, and to about $\frac{1}{20}$ if they roll between two smooth wooden surfaces. Allowing that a man can haul $1\frac{1}{2}$ times his own weight, there would be required to move the stone cover of the temple at Buto, upon smooth ground, 10,000 men; upon a surface of wood, 9,000; with the stone upon a wooden platform and drawn upon wood, 8,833 men; and if the surfaces were soaped, 2,500 men. In raising it upon an inclined plane to place it upon the walls, the increase of force required is in the ratio of its inclination.—The comparative durability of building stones is a matter of the first importance, and received especial attention in England on the occasion of selecting the best variety attainable for the houses of parliament. The effects of the weather upon some of the buildings in that country are noticed in the article SANDSTONE. In the United States the disintegration of building stones is exemplified in a remarkable degree in the old capitol at Washington. In a report of the secretary of the interior to congress in 1849, it is stated that some of the stones near the base of the building were so deeply affected, that it was necessary to remove them. The stone readily absorbs the moisture that condenses upon it, and the natural cement that holds the particles together appears to be dissolved, causing the material to crumble. In the words of the report: "If left wholly unprotected from atmospheric action for one fifth of the time that marble structures are known to have stood, this noble edifice would become a mound of sand. The treasury building and the present patent office building are of the same material, and, having been in no manner protected, already show signs of decay." The only remedy proposed is by some method to render, if possible, the stone permanently and absolutely impermeable to moisture. To test the comparative durability of stones, M. Brard proposed a method, which was afterward adopted by the engineers of bridges and highways in France, and was supposed in its effects to represent the action of frost. According to the directions published by a commission appointed by the royal academy of sciences for inquiring into the value of this process, the specimens to be tested are cut into 2-inch cubes with sharp edges, and boiled for half an hour in a saturated solution of sulphate of soda in an earthen pipkin. The cubes are then taken out and suspended separately by threads over

caps containing a little of the solution in which the stones were boiled. The salt gradually forms small needles on the surface of the stone; and these should be washed off several times a day, for 4 or 5 days, in the cup beneath. If the stone be capable of resisting the action of frost, the crystals are supposed to abstract nothing from it; but if otherwise, small particles will drop off into the cup below, and these being collected and weighed will give the relative character as to durability of each specimen. Although experiments of this kind made in Paris agreed in their results with the effects noticed by long continued exposure of the same stones in buildings, the report on stone for the new houses of parliament (March, 1839) presents many instances of an opposite character. Some specimens well known to decay rapidly in a building disintegrated least of all; and others of the most durable quality disintegrated more than all the rest. This method of testing is consequently not to be depended upon. In fact, it appears from experience that the same stone weathers very differently in different localities; and that the atmosphere of large cities is much more destructive than that of the country. The magnesian limestone selected for the houses of parliament appears to have been satisfactorily proved at Southwell minster, in which, though exposed for 800 years, it still retains every mark of the tool; but in London it is soon found to suffer serious injury, from the effect, it is supposed, of the sulphurous acid in the smoke of the city. The softer limestones are also affected in the same way, so that it has even been necessary to resort to paint to protect Buckingham palace and other important buildings from decay. The Caen stone, it is said, endures well in lower Normandy, while it decays rapidly in Havre, and still more so in London. Some stones also are injuriously affected by the salt water atmosphere, which stand very well in the interior; some again, which are very durable if always either wet or dry, gradually give way when exposed to continual tidal changes; and others that stand well in fresh water disintegrate in salt water. Sandstones in general are least affected by heat, and limestones are readily cracked by it, and even partially calcined. Thus it appears that in selecting stones for structures of importance, special attention should be directed to the peculiar conditions to which they are to be exposed. A method of testing the durability of marbles for the U. S. capitol, adopted by the commission appointed for this purpose, was submitting them many times to the action of freezing mixtures. An account of this is given in *MARBLE*, vol. xi. p. 175. The mode of testing the resistance of stone to the crushing effects of heavy weights is also there described. The value of this proof in important structures can hardly be over-estimated. Prof. Walter R. Johnson states, from his experiments upon some of the marble introduced in the Washington monument at Washington,

VOL. XV.—8

that he considers it not at all improbable that the monument will fall to pieces from its own weight before it is completed. A specimen of the stone in it 4 cubic inches in dimensions sustained a weight of only 9,000 lbs., while a single cubic inch of good material sustained 18,000 lbs. The following are results of trials made in Washington, under direction of the ordnance board, upon the resistance per square inch of some of the most important building stones of the country. Quincy granite or syenite, sp. gr. 2.648, 29,220 lbs.; Pottsdam sandstone from Malone, New York, sp. gr. 2.591, 24,105 lbs.; blue micaceous rock employed for the foundation of the new capitol broke (average of 7 samples) under 15,503 lbs. The compact red sandstone of the Smithsonian institution broke under 9,518 lbs. The strength of several marbles tested varied from 7,000 to 10,000 lbs. The sandstone of the capitol broke under a pressure of 5,245 lbs. The sandstones were tested as they are usually laid in building with the lines of stratification perpendicular to the horizon; but the marbles and granites were tested in an exactly opposite position. Mr. R. G. Hatfield of New York found that the New Jersey and Connecticut sandstones broke under pressures varying from 8,000 to 8,500 lbs. per square inch. In Europe the strength of stones has been the subject of numerous experiments, and is treated by Rondelet, *L'art de bâtir*; Gothey, *Construction des ponts*, in Rozier's *Journal de physique*, vol. iv. (1774); and by Emerson in his "Mechanics." The following are given as the weights which it is judged may be safely borne upon a square foot of the stones named, which is $\frac{1}{3}$ of the actual crushing force:

Variety of stone.	Weight of a cubic foot, lbs.	Safe weight for a square foot, lbs.
Porphyry.....	179.44	640,000
Granite, Aberdeen blue.....	174.90	500,000
" Cornish.....	164.06	196,000
" " ".....	166.87	114,000
Marble, white statuary.....	172.50	109,000
" " ".....	168.87	57,000
" " ".....	170.37	88,000
" veined white, Italian.....	170.37	174,000
" variegated red, Devonshire.....	158.12	129,000
Dundee stone.....	158.12	119,000
Portland stone.....	151.48	82,000
Fourneau pillars of All Saints church at Angers.....	160.69	110,000
Bagneux pillars of Pantheon at Paris.....	187.12	62,000
Stone of temples at Pestum.....	140.87	58,000
Derbyshire grit, a friable red sandstone.....	144.75	56,000
Tuff from Rome.....	76.00	15,000
Chalk.....	97.81	9,000
Brick, hard, well burned.....	97.81	34,000
" pale red.....	180.81	10,100
" red.....	185.50	14,500

The following are weights actually borne upon the square foot of stone in some buildings: the pillars of the church of All Saints at Angers, named in the table, support on each superficial foot a pressure of 86,000 lbs.; the Bagneux stone in the pillars of the dome of the Pantheon at Paris, 60,000 lbs.; a red sandstone pillar in the centre of the chapter house at Elgin, 40,000 lbs.; the piers under the dome

of St. Paul's in London, 89,000 lbs.; those under the dome of St. Peter's at Rome, 83,000 lbs. (See **STRENGTH OF MATERIALS**).—The methods of extracting stones from their beds are described under each variety (see also **BLASTING**); the mode of shaping blocks of stone by sawing in the article **MARBLE**, and of polishing in **LAPIDARY**. The dressing of blocks of stone is usually performed with wedge-shaped hammers by hand, the surface being gradually reduced by light blows, each one being struck in regular order close to the points abraded by the preceding blow. The work upon hard stones is necessarily laborious, and machines have been devised in England and in the United States for accomplishing it by steam power upon several plans. By one method large masses of hard stone are cut by a series of chisels, which follow each other in the same track, each striking a heavy blow, and which are fixed to a frame that travels on a kind of railway. Pavement slabs are cut in Dean Forest by revolving disks, 10 or 12 feet in diameter, which carry on the periphery 20 or 80 cutters. A machine devised by the earl of Caithness, for dressing the surface of hard slabs for street pavements, consists of about 80 iron bars standing vertically by the side of each other and each toothed at the bottom; these are raised successively and fall heavily upon the stone, which is carried along slowly beneath them. The following is an account of a very efficient machine invented by Mr. Charles Wilson of Springfield, Mass., for dressing sandstone. Broad wheels or cylinders are made by placing 8 to 12 disks of steel, 7 inches in diameter, and as thick as a common circular saw of that size, alternating with iron washers $\frac{1}{2}$ of an inch thick and $\frac{1}{4}$ inch less in diameter than the disks. Two such cylinders are adjusted upon their axes so that the cutters stand at an angle of about 25° with a horizontal line, and are then caused to revolve in an "iron head," which passes quickly back and forth across the stone as this is moved slowly along upon its carriage, like that used in saw mills. A rough block of 6 superficial feet has been smoothly dressed in this way in 8 minutes. Marble and other soft stones are sometimes cut into parallel slabs by circular cutters of this kind set upon a horizontal axis, at distances apart equal to the intended width of the strips. Circular pieces are sometimes cut by means of chisels fixed to the ends of revolving horizontal arms. Small circles have been cut with hollow cylindrical chisels made to revolve upon their axes; in this way pillars have been made, and hollow cylinders or tubes of stone. (See **PIPE**, vol. xiii. p. 846.) Stones are sometimes turned in lathes shaped with cutting tools; and mouldings upon flat stones are produced by running the stones through lathes upon which are fixed the tools, sometimes of iron, having the counterpart shape of the moulding to be made. Such tools may be fed with sand and water.—The want of durable

building stones in certain localities, and the extreme labor of dressing them, have led to many attempts to produce artificial substitutes, that might be moulded from liquid or plastic compounds, and which should afterward become solid and durable; and also to produce certain applications which should harden and render more permanent soft stones that are easily dressed. Bricks are successful substitutes for stone, and pottery and terra cotta have been produced in various forms applicable to architectural purposes. The cinders of iron smelting furnaces have also been run into moulds, and strengthened by slow cooling, with the same object; but this application does not seem to have succeeded. It has been also proposed to mould the alkaline solutions of silica (see **SILICATES**, **SOLUBLE**); but their employment seems likely to prove more beneficial in coating the softer stones. Ransome's process, recently introduced into England, by which he produces artificial stones for a great variety of purposes, as grindstones, whetstones for scythes, mouldings, &c., for decorations, tombstones, tablets, and chimney pieces, consists in moulding a mixture of 10 parts of sand, 1 of powdered flint, 1 of clay, and 1 of the alkaline solution of flint, after they have been thoroughly kneaded into a putty-like consistence. The proportions of the ingredients vary with different articles. The moulds are generally of plaster of Paris, oiled over and dusted with finely powdered glass, and the compound is rammed into them with a stick. When the casts are taken out, they are first washed over or floated with a diluted solution of the silicate. To cause the casts to dry equally and to prevent the formation of an external crust impervious to the moisture from the interior, the ingenious expedient was adopted of placing the articles in a close chamber heated by steam, into which a jet of steam is admitted, until the stones attain throughout a temperature of 212° or more. The vapor then being allowed to escape slowly from the chamber, the stones are left uniformly dried. A variety of stony mixtures have been compounded so as to resemble many of the natural stones, and the materials have been held together by cements of different sorts; but none of them have ever been brought into extensive use. The external applications proposed (beside the soluble silica) for protecting the surface of stones are numerous. The most promising of these seem to be of oily, fatty resinous matters, which the stone is made to imbibe, sometimes by being boiled in them. Gutta percha, quicklime, copers, and various other substances have also been introduced into the preparations. Patents were taken out in England in 1856 for applications, first of a solution of sulphate of zinc or of alum, followed by one of sulphur in oil; and another for a solution of wax in coal tar, naphtha, &c.

STONE, the common name of calculus in the urinary bladder, for the composition of

which see *Calculus* and *Gravel*. The prominent symptoms are irritability of the bladder, with frequent irresistible desire to pass water, and occasional stoppage of the stream, with pain in various parts of the urinary system; none of these, however, can be depended on, the only sure diagnosis resting on making the stone perceptible to the ear and fingers by means of a metallic sound introduced through the urethra, and brought into direct contact with the foreign body; even with this instrument, several introductions in various positions of the body are sometimes necessary for its detection. The symptoms vary in intensity according to the size and roughness of the stone, the state of the urine, and the condition of the bladder. Stone may be formed from the urine and from the mucus of the bladder, the latter being always phosphatic; all stones become coated with phosphates if they remain long enough to produce inflammation of the mucous membrane; the phosphatic are the largest stones. Supposing all methods for correcting the diseased condition of the urine and for removing pain and irritation to have been used in vain (see *Gravel*), the only other remedy is to extract the foreign body; this may be attempted in 4 ways, extraction through the urethra, solution by injections into the bladder, lithotomy (Gr. *lithos*, stone, and *tomos*, incision), and lithotripsy or more properly lithotripsy (Gr. *lithos*, and *tribos*, to grind). Extraction by the urethra was employed by the Egyptians centuries ago; it is practicable only for small stones, and especially applicable in females, where the canal is short and nearly straight; in favorable cases, when the irritability of the bladder has been diminished and the organ filled with fluid, the urethra may be dilated by bougies, and small stones be extracted by forceps made for the purpose. Sir Benjamin Brodie has shown that phosphatic calculi may be sometimes entirely dissolved, or so disintegrated as to escape by the urethra, by the injection of very dilute nitric acid; uric acid calculi are more rebellious to this treatment, and the oxalic entirely so. Both these processes are less employed, as the other two methods are more certain, and generally unattended with danger. If the stone be large, sacculated, or very hard, the urethra strictured, the prostate gland enlarged, the coats of the bladder diseased, or the patient very weak and irritable, most surgeons would employ lithotomy in preference to lithotripsy; both these operations are comparatively rare on the Atlantic seaboard of the northern states, but very common in the western and middle states, where limestone strata take the place of the granitic rocks. Supposing the operation not to be contra-indicated by organic disease, and the general and local condition of the organs to be as good as possible, lithotomy may be performed in 4 ways, called respectively the lateral, bilateral, recto-vesical, and high or hypogastric operations. The lateral operation is in general the best, and it may be performed

as follows: a grooved steel staff or sound of full size is introduced, the bladder being moderately distended, the patient on his back, with shoulders elevated, thighs separated widely in order to expose the perineum, the hand grasping the foot and bound together; the patient being etherized, an incision is made on the left side of the perineum from about an inch before the anus downward and outward to a point midway between the anal opening and the tuberosity of the ischium, the muscular fibres being divided down to the staff; the groove is carefully entered by the knife or gorget, the fascia divided forward, and the urethra perforated a little in front of the prostate, the rectum being thrust back by a finger in the incision; the knife is gently pushed into the bladder, slitting up the urethra and dividing the prostate for about half an inch; the finger is then introduced, dilating the opening; the finger being withdrawn, the forceps are introduced, opened, and the stone seized, if possible, with the first gush of fluid from the wound, and then extracted by slow, steady, and undulating movements, dilating and not tearing the soft parts. If properly performed, and the after treatment not interfered with by hæmorrhage, inflammation, sloughing, or other complications, the urine begins to flow by the urethra in about a week, and the wound heals completely in 4 or 5 weeks. In the bilateral operation, a curved incision, with the convexity upward, is made from one side of the perineum to the other, between the anus and the urethral bulb, dividing both sides of the prostate by a double bistoury; the recto-vesical operation consists in cutting into the bladder from the rectum on the median line behind the prostate; and in the high operation the bladder is opened above the pubes through the linea alba, where there is no covering of peritoneum; the last is resorted to when the stone is of great size, the prostate enlarged, or the tuberosities of the ischia too near together. Lithotomy was practised 25 centuries ago; Hippocrates bound his pupils by oath not to practise it, but it came into use again in the time of Celsus, in whose writings are found the first indications of the bilateral operation; the lateral operation was first practised toward the end of the 17th century; the recto-vesical method was first employed by Sanson.—Lithotripsy has for its object to reduce a stone in the bladder by crushing it into fragments so small that they may be expelled by the urethra. The early instruments used for this purpose were very rude and dangerous, the stone being grasped by branches made to protrude from a straight catheter, and then bored by a drill extending through the instrument and worked by a watchmaker's bow; after it was bored it was crushed by another complicated instrument. The next improvement was introduced by Heurteloup in 1880, which consisted in seizing the stone in curved forceps, the anterior sliding in the posterior blade, and then breaking it to pieces by

blows applied outside with a hammer; the instrument was liable to be bent or broken, and the urethra and bladder to be wounded by it or the fragments of the stone. The instrument now used is composed of two sliding blades, introduced in the shape and after the manner of a sound, between which the stone is seized, and then crushed by the gradual pressure of a screw; the fragments may then be washed out by injections or by the urine, large pieces being again broken by the same or a smaller instrument. This operation, by variously modified instruments, is generally preferred to lithotomy, as easier, safer, applicable in a greater variety of cases and at all ages, and quite as effectual.

STONE, a new S. W. co. of Missouri, bordering on Arkansas, intersected by White river, and drained by its tributary the James; area, about 500 sq. m.; pop. in 1860, 2,401, of whom 16 were slaves. The surface is broken and the soil fertile. Capital, Galena.

STONE, FRANK, an English painter, born Aug. 23, 1800, died Nov. 16, 1859. He originally painted in water colors, and in 1837 became a contributor to the exhibitions of the royal academy. Subsequently for more than 20 years he produced many works in *genre* and history, and on subjects of sentiment and imagination. Some of these are well known by engravings, particularly the companion pieces entitled "The First Appeal" and "The Last Appeal," once very popular. He was elected an associate of the royal academy in 1851.

STONE, THOMAS, a signer of the declaration of independence, born at Pointon Manor, Charles co., Md., in 1743, died in Alexandria, Va., Oct. 5, 1787. Having studied law, he commenced practice at Fredericktown, Md., in 1769, and in 1771 removed to Charles co. In 1774 he was by a vote of the provincial deputies added to the Maryland delegation in congress, and in 1775 was rechosen. He strongly favored the establishment of an independent government, although under instruction from the Maryland convention to oppose it; but that state receded from its opposition in time to allow its delegates to sign the declaration. He served on several committees, including that charged to prepare a plan of confederation. Re-elected to congress in 1777, he saw that plan accepted, declined another election, and became a member of the Maryland legislature, where the measure was still opposed. In 1783 he was again elected to congress.

STONE, WILLIAM LETTE, an American journalist and author, born at New Paltz, Ulster co., N. Y., April 20, 1792, died at Saratoga Springs, Aug. 15, 1844. When a child, his father removed to the valley of the Susquehanna. The son received from him thorough instruction in Latin and Greek, and at the age of 17 entered a newspaper office at Cooperstown to learn the printer's trade, and soon began to write newspaper paragraphs. In 1818 he became the editor of the "Herkimer American," and subsequently edited political newspapers at

Hudson, Albany, and Hartford. In the spring of 1821 he became editor and one of the proprietors of the New York "Commercial Advertiser," which position he retained till his death. Though possessing decided ability as a political writer, Col. Stone (as he was always called) preferred literary pursuits to partisanship. In 1825 he was appointed by the corporation of New York to write the narrative of the "Grand Erie Canal Celebration." His tales and sketches published in the annuals were subsequently collected in 2 volumes. "Ups and Downs in the Life of a Distressed Gentleman" (1836), a satirical work, was very successful. Among his more elaborate works were "Letters on Masonry and Anti-Masonry" (8vo., New York, 1833); "Border Wars of the American Revolution" (2 vols. 18mo., 1834); "Matthias and his Impostures" (18mo., 1835); "The Life of Joseph Brant" (2 vols. 8vo., Cooperstown, 1838); "Life and Times of Red Jacket" (8vo., New York, 1840); "The Poetry and History of Wyoming" (16mo., 1841), and "Uncas and Miantonomoh" (12mo., 1842). At the time of his death he was engaged upon a life of Sir William Johnson.

STONE BORER, a name given to several bivalve shells, especially *pholas* (Linn.) and *lithodomus* (Cuv.), from their power of boring into the hardest rocks. The *pholadida* (Gr. *φωλεω*, to hide in a hole) are true bivalves, and have 2 accessory plates in the neighborhood of the hinge for the protection of the dorsal muscles; they belong to the group *siphonophora* (Gray), or those having long respiratory siphons, united for the greater part of their length; they are all burrowing animals, penetrating the hardest substances. The shells are usually elongated, gaping at one or both ends, and closed by 2 adductor muscles; the foot is large and powerful, and the mantle is closed; they are found in all climates. The typical genus *pholas* is often of considerable size, with a white, hard, rough, but very brittle shell, rendering it an interesting question how it can perforate a solid rock; the operation in this case is supposed to be performed by a rotatory motion of the shell effected by the powerful foot. The date shell (*P. dactylus*, Linn.), about 2 inches long and 6 or 7 wide, is found along the European coast, mostly in calcareous rocks; it is eaten along the Mediterranean. The *P. candida* (Linn.), a much smaller species, is extensively used for bait on the coast of Devonshire. The *P. costata* (Linn.), a large species from the West Indies, is sold for food in the markets of Havana. The *P. crispata* (Linn.), much smaller, is found along the coasts of our middle and southern states. Many fossil species are known. The family of *veneracea*, of the same group, are also stone borers, principally by means of the foot.—Among the asiphonate bivalves, the most remarkable stone borer is the *lithodomus lithophagus* (Cuv.); it is commonly found in holes which it has excavated in calcareous and coral formations; it is the sea

date shell of the Mediterranean, and is a delicate article of food. Its perforations have served as important indications of the change of level of the sea coast in modern times; the columns of the temple of Serapis at Puteoli are perforated by these shells at a considerable height above the actual level of the sea.—Another bivalve, coming near the clams, generally considered a stone borer, is *saxicava* (Lam.), which appears under such a variety of forms that 2 genera and at least 15 species have been made of the single representative *S. rugosa* (Lam.); the young symmetrical form constitutes the genus *hiatella* (Bosc). It is found in almost all parts of the world, largest in the arctic seas, in crevices of rocks and corals, assuming very exactly the shape of the cavity which contains it; it occurs from low water mark to the depth of 140 fathoms; it is found fossil in the miocene and glacial deposits. It has been questioned whether *saxicava* is the excavator of the holes in which it is found, and the subject of the mechanism by which the stone borers operate is by no means well understood.—The *pholas* bores into the hardest stone by means of its rough rasping shell, but *saxicava* is smooth, covered with epidermis, and has a very small foot; accordingly some have supposed that a peculiar acid is secreted in many cases, capable of acting chemically on the rocks, and of so softening them that the branchial currents wash away the particles; while others have called into play the thickened anterior margins of the mantle, covered with silicious grains which act like a rasp. The perforations made in shells by *natica* seem more like chemical than mechanical action, the solvent being most concentrated where it is immediately used, and not necessarily acting, in its otherwise diluted state, on the shell of the animal secreting it; the excavations of *saxicava* are attributed also to the action of the brushes of vibratile cilia along the edges of the mantle. After all the explanations offered, it is possible that the excavations are only occupied, not made, by *saxicava*; the finding of this shell, and *crepidula*, *petricola*, &c., in cavities which fit them exactly, may be rather an evidence of a power of adaptation of their external form to the cavities into which they enter than of ability to perforate.—Sea urchins also may in many instances be called stone borers, the excavation of their cavities being effected by the constant action of their spines, and perhaps also by the vibratile cilia of their ambulacral tubes and suckers. It is conceivable, if not probable, that the continual action of soft vibratile cilia may excavate holes even in the hardest rocks.

STONE-CHAT (*saxicola rubicola*, Bechst.), a dentirostral bird of the warbler family, and sub-family *erythacinæ*, or old world robins. The bill is short, with broad gape furnished with bristles; wings long and rounded, with 4th and 5th quills equal and longest; tail short and broad; tarsi and toes slender, and hind toe

long. There are several species of the genus; they prefer open and rocky grounds covered with furze, and are usually seen singly or in pairs hovering about these bushes and from stone to stone, uttering a quick but agreeable chattering song, which has given the above name to the best known species; the food consists of worms and insects, the latter being generally seized on the wing in the manner of the flycatchers; the nest is on or near the ground, carefully concealed, and the eggs 6. The stone-chat is about 4½ inches long; the head, throat, and back black, on the latter edged with whitish red; sides of neck, upper part of wings, and rump, white; breast orange brown; lower parts reddish white. It is resident in England, but migratory on the continent. A similar but migratory species is the whin-chat (*S. rubetra*, Bechst.), so named for its partiality for furze or whin bushes; it is 4½ inches long, with the top of the head and upper part of the body blackish brown, each feather bordered with reddish and yellow; broad band above eyes, stripe on sides of neck, and large spot on wings and tail, white; breast rose-colored; 2 middle tail feathers dusky. These 2 species belong to the sub-genus *pratinea* (Koch). Another European species (*S. ananthe*, Bechst.) sometimes straggles into North America from Greenland; it is called stone-chat by Baird, but is more properly styled the wheatear.

STONE LILY, the popular name of the fossil radiated animals of the class of echinoderms and order of crinoids, and especially of the group called encrinurites. They have some resemblance to petrified lilies in the plates at the base of the body, bearing the arms and their divisions, and supported on a long, jointed stem. The perforated joints of the stem are used in rosaries, and are known in the north of England, where they are abundant, as St. Cuthbert's beads. Most of them are fossil forms, very numerous during the secondary epoch, vast strata of limestone and marble in North America and Europe being formed by the myriads of their petrified remains. They were attached at the bottom of the sea, the flexible stems yielding to the force of the waves. The genus *pentacrinus* is found living in the West Indies. (See CRINOIDEA, and ENCRINURITES.)

STONEHENGE, a collection of huge stones on Salisbury plain, Wiltshire, England, about 9 m. N. from Salisbury. Seen from a distance, they appear to be merely an irregular mass of stones, but a closer inspection shows them to have originally constituted a rude architectural structure, arranged in two circles and two ovals. There are altogether about 140 stones, the smallest estimated to weigh 10 or 12 tons, and the largest 70 tons. They are much weather-worn, but in many of them the sharp angles and the tenons and mortises by which they were joined are well preserved. Most of those on the outer circle are standing, and the whole work is surrounded by a circular earth embankment 15 feet high, and a trench 30 feet

wide and 1,009 feet in circumference, and approached by a straight avenue similarly formed 594 yards long, divided into two branches at its outer extremity. There are other earth-works and numerous ancient barrows or burial mounds in the neighborhood. In the centre of the work is a massive slab of fine sandstone, supposed to have been an altar. Among the ruins have been found the relics of human bodies, and of oxen, deer, and other animals.—Stonehenge has given rise to much speculation and discussion among the learned in regard to its origin and purposes. History throws no light upon the subject. According to Geoffrey of Monmouth, it was erected by order of Aurelianus Ambrosius, the last British king, in honor of 460 Britons slain by Hengist the Saxon; but Polydore Vergil argues that it was a monument to the memory of that king. Inigo Jones believed it to have been a Roman temple, and Rickman attributes it to the post-Roman period. Dr. Charleton conjectured that it was built by the Danes during their temporary possession of Wiltshire. The theory best sustained by antiquaries and most plausible is that it was a druidic temple.

STONINGTON, a town and port of entry in New London co., Conn., at the E. extremity of Long Island sound, 68 m. E. from New Haven, and 50 m. S. S. W. from Providence; pop. in 1860, 7,740. It is built upon a peninsula nearly a mile long, and has a commodious harbor protected by a breakwater. It has a flourishing coasting trade, and was formerly largely engaged in whale fishing. On June 30, 1860, its shipping amounted in the aggregate to 19,587 tons, of which 7,305 tons were registered, and 12,282 enrolled and licensed; and 2,484 tons were engaged in whale fishing, 10,063 in the coasting trade, and 1,741 in the cod fisheries. There are 3 banks, a savings bank, a newspaper, 12 churches, and a number of manufactories of various kinds. The New Haven and Stonington railroad connects it with New Haven and New York, and the Stonington and Providence railroad with Providence and Boston.—The town was settled in 1649, and incorporated in 1807. On Aug. 9, 1814, it was attacked by the British fleet under Sir Thomas Hardy, and during that and the next day several attempts were made to land; but the militia speedily gathered and compelled the enemy to retire.

STONY POINT, a small rocky promontory on the right bank of the Hudson river, in Orange co., N. Y., 42 m. N. from New York, at the entrance of the highlands, and opposite Verplanck's Point. On both these points forts were built by the Americans during the revolution, which were captured by Sir Henry Clinton, June 1, 1779, strengthened, and strongly garrisoned; but that on Stony Point was retaken by a bold night attack under Gen. Anthony Wayne, with 550 men, July 16, and the garrison of 543 officers and men made prisoners. The Americans had 15 killed and 88

wounded, and the British 63 killed. The simultaneous attack on Verplanck's Point having failed, the works on Stony Point were destroyed and abandoned on the 18th.

STOPPAGE IN TRANSITU, in law, the arresting by the seller of goods on their passage to a distant purchaser who has become insolvent. Though the right to do this originated with and is still most frequently exercised in respect to water-borne goods, yet it is well settled that it applies as well in the case of goods carried by land. When and how the doctrine of stoppage in transitu became a part of our law cannot be definitely asserted. As to the time, its introduction was comparatively recent; as to the mode, it may have been in either of three ways: 1, by adoption from the continental law of that principle of the law of sales which considers that the right of property (the *jus in re*) does not pass to the buyer until he has possession of the goods, so that the seller continues to own the goods until they reach the buyer; 2, by supposing that the seller had, until the goods reached the buyer, a right to rescind the sale for non-payment, provided the buyer became insolvent, and that the act of stoppage in transitu was an exercise of the right. This last was at one time rather a favorite view, but the prevailing course of adjudication in the United States is decidedly against it. The third way is by considering that the common law doctrine of the seller's lien for the price on the goods sold so long as he has them in his possession, continues in force after they have left his possession, and until they have reached that of the buyer; or, in other words, that the goods are considered constructively in the possession of the seller until the buyer has actual possession. Perhaps a combination of the first and third of these ways will best account for the right of stoppage in transitu as it exists in the English and our own law; that is to say, the rule of the civil or continental law, recommending itself by its reason and justice, established itself in the law merchant. When, as a part of that system, it came to the observation of the English courts, they recognized its reasonableness, and sought to support it by some familiar principle of the English law. This they found in the law of lien and in the continued constructive possession of the seller; and upon this law, and adopting its general principles, they founded the law of stoppage in transitu.—The right exists only between a buyer and a seller. A surety for the price of the goods, bound to pay for them if the buyer does not, has not this right; but every one who is substantially a seller has. Thus, one ordered by a foreign correspondent to buy goods for him, and then buying them in his own name and on his own credit, and sending them as ordered, may stop them *in transitu*. So may a principal who sends goods to his factor, or one who remits money for any particular purpose. The reception and negotiation of a bill for the goods does

not defeat the right, nor does part payment. But goods cannot be stopped when they are sent to pay a precedent and existing debt.—The right arises only upon actual insolvency, which however need not be legal or formal bankruptcy or insolvency. It is enough if the buyer cannot pay his debts; and it is enough, too, if the buyer refuses to comply with the specially agreed terms of the sale, for this is insolvency so far as the seller is concerned. When the goods are stopped, the buyer may, by payment of the price or by tender of security if they were sold on credit, defeat the stoppage and reclaim the goods. If the seller stop the goods maliciously, and without actual belief of the insolvency on good grounds, he would doubtless be answerable for any damages which the buyer might sustain. The seller's right to stop the goods cannot be defeated by any bargain between the consignee and his assignee, or by any claim or lien or attachment of any other person. In some cases it may be necessary for the seller to discharge the claim before he can have complete control of the goods, as for example in case of a lien for freight; but this is not necessary when the attachment is by a creditor of the buyer or consignee, because the seller's lien has the precedence.—Nice questions have arisen in respect to the *transitu*. Generally speaking, the goods are in transit when they are not in the actual possession either of the buyer or of the seller. But the law goes sometimes further than this, and inquires into the constructive possession; for the goods may be in the actual possession of the seller, and yet so far constructively in the possession of the buyer that the seller cannot retain them; or they may be in the actual possession of the buyer, but under such circumstances that the seller's right is not taken away. It becomes, therefore, very important to ascertain in many instances whether the transit is or is not complete. A carrier of goods, by land as well as by sea, acquires a lien on the goods which he carries for the freight money. The goods are still in transit, and may be stopped, so long as the carrier withholds them from the buyer by his lien for the freight, and a seller who seeks to stop them then must discharge this lien. In general, whenever a carrier enters into a new arrangement with the consignee, by which he agrees to hold the goods as the property of the consignee and at his disposal, there is a termination of the transit. Yet all acts in reference to such question must be open to explanation by existing circumstances, the general inquiry in such case being whether the carrier, warehouseman, wharfinger, or other person having actual possession of the goods at the time of the intended stoppage in transitu, was then acting as the agent of the seller or of the buyer; for if of the latter, the transit was terminated. If the buyer order the goods to be sent to some other person by any suitable conveyance without designating any one especially,

or by a designated carrier who is not specially his agent or servant, the goods remain in transitu until they reach that second person. Questions of constructive possession arise very frequently in respect to goods in the charge of warehousemen. In general, every warehouseman is the agent of any party who puts the goods in his warehouse and can take them out at his pleasure; and therefore his possession is the possession of such party. This is carried so far, that where a seller had a warehouse, and it was part of the bargain of sale that the goods might remain in his warehouse until the buyer took them out, without charge, and they remained there after the sale under this bargain, it was held that the actual possession of the seller was the constructive possession of the buyer, and that the seller could not stop or retain them for the price. On this point it is a material question whether any thing remains to be done by the seller; if nothing, this goes far to make the warehousing a delivery to the buyer. If a seller of goods that are warehoused delivers an order for them to a buyer, this alone may not transfer the possession; but if the buyer delivers the order to the warehouseman, this in general transfers the possession, and still more so if the warehouseman enters the same in his books or otherwise accepts the order, so as to be responsible for the goods to the buyer. If the buyer sells to a third party, to whom the warehouseman certifies that the goods are transferred to his account, and who thereupon pays the price, the warehouseman becomes responsible to this third party; and if the original seller, though there remained something material to be done by him to the goods, justified the warehouseman in so certifying, he would be held to have lost his right of stoppage in transitu.—The effect of the bill of lading upon the right of a seller to stop the goods in transitu is very important. The law merchant regards the bill of lading, not as a mere receipt which the carrier gives for the goods, but rather as a muniment of title, carrying property with it, and of itself a negotiable instrument. This view, in its entire breadth, the common law has not yet adopted. It admits, however, that the bill of lading is *quasi* negotiable, and that an indorsement and delivery of it for value operate as a symbolio delivery of the goods mentioned in it. It results from this doctrine that a consignee, who sells for value goods to arrive and indorses over the bill of lading, confers upon the purchaser a title and property which destroy the right of the seller of the goods to stop them in transitu. If, however, the party buying from the consignee knows that the sale is in fraud of the original seller, it is voidable by that seller of course; and if he knows that the consignee is, or is about to become, insolvent, this knowledge would probably have the same effect. Generally, the purchaser's claims will be defeated, not only by his knowledge or adequate means of knowledge of the consignee's

fraud, but by knowledge or notice of any circumstances which rendered the bill of lading not properly assignable. If the bill of lading be transferred and indorsed by way of pledge to secure the consignee's debt, the consignor does not lose entirely his right to stop the goods, but holds it subject to the rights of the pledgee. That is, he may enforce his claim to hold the surplus of the goods after the pledgee's claim is satisfied; and he holds this surplus to secure the debt of the consignee to him. But the pledgee's claim, which the consignor is thus bound to recognize, would not be for a general balance of account, but only for the specific advances made upon the security of that particular bill of lading; and therefore, by paying or tendering that amount, the consignor acquires the right of retaking all the goods.—The insolvency of the buyer, however complete or however manifested, will not operate of itself as a stoppage in transitu. The goods must be actually stopped, in some way which the law recognizes as adequate, by the seller or his authorized agent. An actual taking possession by the seller is however not necessary, at least not in all cases, although actual possession should be taken if possible, and as soon as possible. Yet a constructive possession may suffice for the seller. This is usually and properly acquired by giving notice to the carrier of the title and purpose of the seller, forbidding him to deliver the goods to the buyer, and requiring him to give them up to the seller or his agent, or to hold them subject to his order. This notice should be given to the person who has actual possession of the goods. If the carrier, after sufficient notice to the contrary, actually delivers the goods to the buyer, the delivery does not defeat the seller's right. He has still a constructive possession, and the carrier is responsible to him for all the injury he may sustain. Or, if the buyer becomes insolvent, and the goods pass into the possession of his assignees, the seller may maintain an action of trover against them. What the consignor may do personally, he may do by his agent; and if the demand be made by one who acts as agent, but without authority, a subsequent adoption and ratification will have the effect of a previous authority, provided this be made before the goods are demanded by the buyer.

STORACE, STEPHEN, an English composer, of Italian extraction, born in London in 1768, died there, March 19, 1796. He received his musical education at the Conservatorio San Onofrio, Naples, and subsequently visited with his sister Anna, an accomplished singer, some of the chief cities of Europe. Returning to England in 1787, he was soon after appointed composer to Drury Lane, in which capacity he produced the "Haunted Tower," "No Song, no Supper," "The Pirates," "The Iron Chest," all successfully performed on the stage, and a number of miscellaneous pieces.

STORAX. See **BALSAMS.**

STORK, a wading bird of the heron family, sub-family *ciconina*, and genus *ciconia* (Linn.); other allied genera are the jabiru and marabou, described under their own names. In the storks the bill is long, straight, strong, gradually tapering to a sharp tip; sides compressed; wings long and ample, the 3d and 4th quills the longest and equal; tail short and broad; tarsi long and scaled; toes short and stout, webbed to the 1st joint; hind toe elevated, partly resting on the ground. They are large birds, most abundant in warm countries, and performing periodical migrations to and from the marshy regions of Europe, Asia, and Africa; like vultures and other carrion feeders, they eat almost any kind of garbage that comes in their way, and are hence valuable scavengers in hot climates; they seek their food on the borders of streams; the body is light and well balanced; during flight the head is thrown back and the legs extended; the space round the orbits is destitute of feathers, and in some the whole face and throat are naked. There are about a dozen species, of which the best known is the white stork (*C. alba*, Briss.); it is 3½ feet long, the bill 7½ inches; the general color is white, with the quills and wing coverts black, and bill and feet red; around the eyes a bald blackish circle; it is the *cigogne* of the French. They arrive in N. Europe, especially in Holland and Germany, in the spring, returning in the autumn to Africa by night and in large flocks; the only noise they make is by clapping the mandibles together like a pair of castanets; they rest sleeping on one leg, with the neck folded and head turned backward on the shoulder. The food consists of reptiles, fish, young birds, and insects. The flesh was once considered a dainty dish, but is not now eaten; many famous medical preparations were in old times made from these birds. The nest is large, coarsely made of sticks and twigs, placed on housetops (often in the midst of crowded cities), and is repaired by the males year after year; the eggs are 8 or 4, white tinged with buff, 2½ by 2 inches; both sexes incubate, and the young are hatched in about a month; the nestlings are tenderly cared for, and are fed by food regurgitated from the parents' stomachs. The flight is very high, and the gait slow, with long and measured steps; the disposition is gentle, the manner familiar, and the docility considerable; they do not propagate in captivity, and have rather a melancholy look. According to the ancient mythology, Antigone, the sister of Priam, was changed into a stork by Juno for having boasted of her superior beauty; but the jealous goddess left her with all her virtues and amiable qualities; the stork, accordingly, has been considered by the ancients as the personification of piety, conjugal and filial love, gratitude, and temperance; it was supposed to bear a charmed life, and it was a crime to offer it violence; in some places it was even an object of worship, and in hieroglyphic language is the symbol

of piety and beneficence; "pious" or "beneficent" is also the meaning of its name in Hebrew (*hasidah*). In Holland it is always welcome as a harbinger of spring, and a house honored by a stork's nest is regarded with special favor; it is of great benefit to man in destroying serpents, frogs, lizards, mice, and other noxious animals; the attachment to its young and to its parents is proverbial. The black stork (*C. nigra*, Bechst.) is about 2½ feet long, with a bill of 5½ inches; the color above is black with green and purplish gloss, and white below; it avoids the vicinity of man, nests in trees, and feeds like the herons chiefly on fish; it is found in many countries of Europe, especially in the Alps. The American stork (*C. Americana*, Briss.) is about as large as the white species; it is found in South America, particularly in Brazil.

STORM BIRD. See **PETREL**.

STORR, GOTTLÖB CHRISTIAN, a German theologian, born in Stuttgart in 1746, died there in 1805. He was appointed professor of theology at Tübingen in 1775, in the same year superintendent, and in 1795 court preacher at Stuttgart. He was a chief representative of orthodox Lutheranism. He was the author of treatises on the Syriac translations of the New Testament and on the Arabic Gospels, a commentary on the Epistle to the Hebrews, and other works. His "Biblical Theology," written in conjunction with Flatt, was translated by Prof. S. Schmucker (8vo., New York, 1838).

STORRS, RICHARD SALTER, JR., D.D., an American clergyman, born at Braintree, Mass., Aug. 21, 1821. He was graduated at Amherst college in 1839, and completed his studies at Andover theological seminary in 1845. In the latter year he was ordained pastor of the Harvard Congregational church, Brookline, Mass., but a year later became pastor of the church of the Pilgrims, Brooklyn, N. Y., which position he still retains; and he has been associate editor of the "Independent" newspaper since its commencement in 1848. He has published 12 or 14 sermons, orations, and addresses; a very elaborate report on the revision of the English version of the Bible undertaken by the American Bible society some years since; a volume of "Graham Lectures, on the Wisdom, Power, and Goodness of God, as manifested in the Constitution of the Human Soul" (New York, 1856); and some minor works.

STORTHING. See **NORWAY**, vol. xii. p. 411.

STORY, a central co. of Iowa, intersected by Skunk river; area, 550 sq. m.; pop. in 1860, 4,052. The surface is undulating and the soil fertile. It is on the line of the projected Iowa central railroad. Capital, Nevada.

STORY, JOSEPH, an American jurist and judge, born in Marblehead, Mass., Sept. 18, 1779, died in Cambridge, Sept. 10, 1845. His father, Dr. Elisha Story, was an ardent whig of the revolution, who in 1770 removed from Boston to Marblehead. The son was graduated at Harvard college in 1798. At the uni-

versity he was distinguished for his devotion to general literature and poetry, and cultivated a more than ordinary talent for versification. On leaving college, he returned to Marblehead, and began the study of law in the office of Samuel Sewall, afterward chief justice of the supreme judicial court of Massachusetts. In Jan. 1801, he removed to Salem, and finished his legal studies with Samuel Putnam, who subsequently became an associate justice of the same court. In July, 1801, he was admitted to the bar and commenced practice in Salem. His political opinions and connections were with the republican party, then in a small minority in the county of Essex; and the social differences caused by political feeling seemed likely for a time to impede his success. But his industry, learning, and fidelity, as well as his engaging manners, not only won him clients and gave him a lucrative and honorable practice, but also, notwithstanding the heats of party, secured for him the warm friendship of some of the leading federalists, and especially of the Hon. William Prescott, then at the head of the Essex bar. At this period (1804) he published a volume of poems containing "The Power of Solitude" and some smaller pieces; but it was not successful. He then, to use his own words, "took a lawyer's farewell of the muse, and, following out the precepts of Blackstone, plunged at once into the dark labyrinth of the ancient learning of the law." He became, in short, at this time a great student, notwithstanding the cares of a large practice; pushing his researches into the whole black-letter learning of the common law, as well as into the more modern systems of commercial and maritime law, and laying the broad and deep foundations of that extensive knowledge of jurisprudence for which he became afterward so much distinguished, and in which he was surpassed by no American, if by any, jurist of his own time. In 1806 he was elected to the lower house of the legislature of Massachusetts, of which he remained a member until the autumn of 1808. He took a very active part in the business of the house, as the principal leader on the republican side; but in two of the measures which he espoused, he acted upon purely independent grounds. The first was a bill to increase, and to establish on a permanent basis, the salaries of the justices of the supreme judicial court. The state constitution of 1780 had provided "that permanent and honorable salaries shall be established by law for the justices of the supreme judicial court; and that if it shall be found that any of the salaries aforesaid, so established, are insufficient, they shall from time to time be enlarged, as the general court shall judge proper." Down to the year 1807, however, the regular salaries fixed by law had continued to be entirely inadequate, and they were occasionally eked out by special grants, made generally upon the petition of the judges. In 1806 Theophilus Parsons was appointed chief

justice; but he made it a condition of his acceptance that the salaries should be placed upon a constitutional footing, and this condition he communicated to Mr. Story, who undertook to carry a bill through the legislature for this purpose. His report on the subject treated the practice of low salaries and legislative grants, which had until that time prevailed, as an insufficient compliance with the constitution of the state, and strongly condemned it as unjust and impolitic. By his zealous exertions, a bill was passed (1807), by which the salaries were raised and permanently established. The other measure introduced and advocated by Mr. Story, in disregard of party lines, was a bill (1808) to establish a court of chancery for the state; but he was not successful. In the same year he defended the embargo as the only measure which the administration of Mr. Jefferson could have adopted, short of a declaration of war, without submitting to the ignominious restrictions on American commerce by the belligerent powers. He had previously (1806) written the celebrated "Memorial of the Inhabitants of Salem relative to the Infringements on the Neutral Trade of the United States," addressed to the president and to congress. In the autumn of 1808 he was elected to congress from the Essex district. In opposition to the wishes of the administration he exerted himself to procure a repeal of the embargo. This defection from his party was warmly resented by Mr. Jefferson. But Mr. Story separated himself from the administration on the question of continuing the embargo, upon the ground that he had originally supported it as a temporary measure; that as such it had done all the good of which it was capable; that it was then doing uncompensated mischief; and that its continuance as a permanent law would endanger the authority of the government and the perpetuity of the Union. He left congress before the repeal was consummated, but not before he had largely contributed to bring it about; and indeed Mr. Jefferson attributed it almost wholly to his exertions. While there, he endeavored to effect an increase of the navy, but without success. Declining a reelection to congress, he was again chosen to a seat in the legislature of Massachusetts in 1810, and in Jan. 1811, he was elected speaker of the house. His character as a presiding officer is thus sketched by one of his contemporaries: "He was a most efficient and business-despatching presiding officer, and with such tact and rapidity did he manage the business of that crowded and sometimes stormy house, that it seemed often to be left with him to do with it pretty much as he pleased; and the question in controversy was often got through with, and was satisfactorily disposed of, before a large portion of the greener members knew exactly what it was, or in what stage of consideration it stood." On Nov. 18, 1811, he received from President Madison the appointment of associate justice of the supreme

court of the United States, in place of Mr. Justice Cushing, then recently deceased; and on Jan. 17, 1812, he resigned the office of speaker. He now commenced that long judicial career, extending through a period of 34 years, for which he was eminently qualified by natural gifts and acquired tastes, and in which he not only won great fame as a judge, but achieved both a European and an American reputation as a comprehensive and philosophical jurist, before he began the publication of the works which he produced in the discharge of his duties in the law school at Cambridge. In 1820 the people of Massachusetts instituted a convention for the revision of their state constitution. Of this body, comprehending many of the most eminent citizens of the state, in all the walks of life, Judge Story was a very important member. His principal services in the convention related to the tenure and the compensation of the judiciary, the apportionment of the house of representatives, and the property basis of the senate. The original constitution contained, as we have seen, a clause authorizing the legislature to increase the salaries of the judges of the supreme judicial court. A motion was made and suddenly carried in the convention, to insert the words "or diminish." The reconsideration and rejection of this amendment were produced by a powerful and brilliant argument by Judge Story, which commanded the assent of more than two thirds of the convention. In committee, he advocated the district system, and the apportionment of representatives according to population, so as to reduce the number of the members; but this plan, although resorted to nearly 40 years afterward, was not then adopted. The senate had been since 1780 founded upon property, by a provision which assigned the members in the proportion of the public taxes paid by the districts which they represented. A great effort was made in the convention to overthrow this provision; but it was successfully defended by Judge Story and other leading persons, and it was not until 1840 that it was abolished, and a system of representation in the senate based purely upon population adopted. In 1829 Judge Story was appointed professor of law in Harvard university, on a foundation established by the Hon. Nathan Dane, for the delivery of lectures on the five branches of law and equity in force throughout the United States, namely, the law of nature, the law of nations, commercial and maritime law, federal law, and federal equity. For the better discharge of the duties of this professorship, he removed to Cambridge in Sept. 1829, and continued to reside there until his death. As the founder of the Dane professorship had foreseen, when he requested the appointment of Judge Story, the law school of which the latter now became the head immediately attracted students from all parts of the United States, and has continued to preserve the rank won for it by his labors, assisted by those of his colleagues, Professors Ashmun and

Greenleaf. From the time of his accession to the bench until his death, his learning, activity, zeal, and industry continually impressed themselves upon society in various functions, official and voluntary, in all of which he exercised a wide influence upon the time in which he lived. This long period comprehends his judicial life, his career as a professor and a juridical author, his services as a member of the corporation of Harvard college, and the many important but less conspicuous capacities in which he promoted the welfare, the literary culture, and the social improvement of his age and country. As a judge, he was eminently distinguished for the rapidity and ease with which he brought the copious stores of his learning to bear upon the subjects litigated before him, in tribunals embracing a wide range of jurisprudence; and if sometimes, from uncommon ardor of mind, combined with extensive knowledge, he announced conclusions apparently too soon, they were rarely such as move deliberate examination required him to modify, nor if they were did he lack the power to change them when they had been reviewed. In his constitutional views he was of the school of Washington and Marshall, upholding what he considered as the just powers of the federal Union, without encroaching upon the separate rights of the states. The long series of his juridical works, which have largely tended to widen and perpetuate his influence as a jurist, are marked by an extraordinary affluence of learning, luminous expositions, and profound views of the science of law. Few lawyers in any country have written so much, and no one has written more practically; for although primarily designed as text books for students in the law, there is not one of his treatises that does not occupy an important place in the library of the practitioner, wherever the system of jurisprudence which it touches is known and administered. They comprehend a full commentary on the constitution of the United States; an elaborate and exhaustive work on the "Conflict of Laws;" treatises on the law of bailments, agency, partnership, bills of exchange, and promissory notes; and commentaries on equity jurisprudence and equity pleadings. The materials, where the subjects admitted of such an excursive treatment, are drawn, not merely from the common law of England or America, but also in a large degree from the civil law, as practised by the Romans or by the modern nations of continental Europe. All of these works have passed through many editions. Judge Story was gifted with great colloquial powers, and his social qualities in private life largely added to the influence of his learning, talents, and public positions. A life of him by his son, William W. Story, was published at Boston in 1851 (2 vols. 8vo.). There is also a collection of his "Miscellaneous Writings" (8vo., 1854). His decisions as a circuit court judge are contained in 13 vols. 8vo., being the reports of Gallison, Mason, Sumner, and Story. His judgments pro-

nounced in the supreme court of the United States may be found in the reports of Cranch, Wheaton, Peters, and Howard, from 1811 to 1845.—**WILLIAM WETMORE**, an American lawyer and sculptor, son of the preceding, born in Salem, Feb. 12, 1819. He was graduated at Harvard college in 1838, studied law, and was admitted to the bar in Boston. In 1844 he published a "Treatise on the Law of Contracts," which was well received by the profession, and has passed through several editions; and in 1847 a "Treatise on the Law of Sales of Personal Property," which has reached a 3d edition. He also published 8 volumes of "Reports of Cases argued and determined in the Circuit Court of the United States for the First Circuit" (1847). Mr. Story's tastes were however more for literature and art than for the practice of the law. In 1847 he published a small volume of poems; in 1851 an elaborate and interesting life of his father (2 vols. 8vo.); and in 1856 a second volume of poems, which in originality of thought and grace of expression were decidedly in advance of his first. Mr. Story is now (Jan. 1869) and for many years has been a resident of Rome, devoting himself to the art of sculpture, for which he early showed a strong inclination. Among his works are a sitting statue of his father, in marble, in the chapel at Mt. Auburn; a shepherd boy, a statuette of Beethoven, several busts, and a model for a statue of Cleopatra which has been highly commended by all who have seen it.

STOTHARD, THOMAS, an English painter, born in London, Aug. 19, 1755, died there, April 17, 1834. His talent for drawing developed itself when he was 5 years of age, and at 14 he was apprenticed to a designer of patterns for brocaded silks. Soon after his 20th year he became a designer for illustrated books, and studied painting at the royal academy, of which institution he was in 1794 elected an academicien, and in 1812 succeeded Mr. Birch as librarian. As a designer he is known by his contributions to "Boydell's Shakespeare," his "Canterbury Pilgrims," the "Flitch of Bacon," and the Wellington shield, and particularly by his illustrations of Rogers's "Poems" and "Italy." During the period when annuals were in fashion his pencil was often employed in illustrations for them. The number of his designs is estimated at 5,000, of which 3,000 have been engraved. His life, accompanied by numerous illustrations from his works, including the design for Chantrey's "Sleeping Children" in Lichfield cathedral, has been written by Mrs. Bray, the widow of his son Charles Alfred (4to., 1851).—**CHARLES ALFRED**, son of the preceding, born in London, July 5, 1786, died at Beer Ferrers, Devonshire, May 27, 1821. He studied painting at the royal academy, and in 1811 he published the first number of a work on the "Monumental Effigies of Great Britain," designed as an aid both to the historical painter and the player, which obtained great success. Having been appointed in 1815 histori-

cal draughtsman to the society of antiquaries, he executed for them during the next 4 years a complete series of drawings from the Bayeux tapestries, and contributed to the 19th volume of the "Archæologia" a paper showing the tapestries to be a work coeval with the Norman conquest of England. Throughout his life he was indefatigable in his efforts to perpetuate by means of drawings the relics of mediæval art in England. While engaged in tracing a portrait from one of the windows in the church at Beer Ferrers, he fell from a height of 10 feet and was killed on the spot. His work on monumental effigies was completed by his widow, now Mrs. Bray, who also wrote a memoir of him.

STOVE (Ang. Sax. *stofa*), an enclosed fireplace, used for warming rooms, cooking, &c.; also an open fireplace when this is movable. The term was also formerly applied to the room itself, heated by a fire. Some of the early methods of heating rooms are described in the article CHIMNEY. Stoves are of comparatively modern invention, and were probably first in use in the countries of the north of Europe, built of bricks and tiles of massive forms, and somewhat resembling large ovens. Dr. Franklin, who was one of the earliest writers on the subject of stoves, and himself invented some very ingenious forms of them, observes that "the Swedes, Danes, and Russians are said to live in rooms, compared to ours, as hot as ovens;" and again, that "though those countries have been well inhabited for many ages, wood is still their fuel, and yet at no very great price, which could not have been if they had not universally used stoves, but consumed it, as we do, in great quantities by open fires." The arrangements for warming apartments were exceedingly defective at the time of Dr. Franklin's inventions, which were first made in 1745. Cardinal Polignac had published in 1709, under the assumed name of Gauger, a treatise entitled *La mécanique du feu, ou l'art d'en augmenter les effets, et d'en diminuer la dépense*; and of this was published in London in 1716 a translation by Dr. Desaguliers, who modified the Polignac fireplaces, which were constructed with hollow backs, hearths, and jambs of iron, so as to adapt them for burning coal as well as wood. Count Rumford afterward introduced the same principle into stoves. The Holland stoves, described by Dr. Franklin, were plain iron box stoves, with a flue proceeding from the top, and a small iron door opening into the room. He speaks of them as using little fuel, the heat being almost all saved, and as carrying off comparatively but little air through the small flue, and of the circulation thus created as being beneficial in ventilating the apartments. They attracted little favor in England, principally because the fire could not be seen; and the same prejudice has ever since operated to prevent the general use of close stoves in that country. The German stove, as described by Dr. Franklin, was also an iron box made of 5 plates put together and fastened by screws,

leaving one side open. This side was set outside of the room, the stove itself projecting through the partition. While all trouble from smoke in the room is thus avoided, the advantage of ventilation through the stove flue is lost. Dr. Franklin's stove, invented in 1745, was a great step in advance of all the older forms. It was a rectangular box of cast iron plates, open in front except near the top, with a sliding shutter by which the whole might be closed entirely or in part, either for safety or for increasing the draught. The hearth projected in front, and was cast with double ledges to receive the edges of the upright plates; and also with a number of holes, viz.: one in the front part with a regulating valve for admitting air to the fire from an air flue beneath when the shutter was down; one behind the first upright plate in the back, for discharging the air brought under the hearth from without into a narrow rectangular air box that was as long as the width of the stove, and as high excepting the space for the smoke flue over its top; and lastly 8 holes near the extreme back edge for the smoke, after it had passed over the air box and descended behind it, to enter the flue leading into the base of the chimney. The air box at its sides was furnished with holes through which the heated air was admitted into the room, and a succession of shelves one above another was provided in this box, reaching not quite across, by which the circulation of the air was extended and it was longer exposed to the heated surfaces before passing out into the room. The back plate of the stove, heated by the descending smoke flue, imparted heat to the air between it and the chimney, the stove standing a little out from the wall. A register of sheet iron was introduced in the descending flue, which could be closed wholly or in part, and check the fire to any desired extent. Thus this stove embodied the principles of the modern air-tight stoves, and the directions Dr. Franklin gave for using it are just as applicable to these, though, by reason of its ruder workmanship, the joints were not air-tight, which the inventor himself remarked, and supposed could not well be otherwise. This stove was ornamented in front with a representation of the sun, near which were the letters, intended for the name of the stove, *Alter Idem*. In 1771 Dr. Franklin completed and used in London a stove designed for burning bituminous coal and consuming its own smoke. It was a vase-shaped iron vessel for receiving the fuel, set upon a horizontal grate, and beneath this was a large box of cast iron, furnished with partitions, which caused the flame and smoke drawn down through the grate to circulate around until they finally escaped into the chimney by a flue at the bottom on each side. With the same object of consuming the smoke, he also invented a basket grate or cage, with movable bars at the top and bottom. The fuel being introduced at the top and kindled, the cage might then be turned over upon pivots, which

supported it by the centre. The name of Count Ramford afterward became celebrated for the improvements which he introduced in stoves, especially those designed for culinary purposes. He greatly reduced their dimensions, and contrived that most important feature in all cooking stoves, of arranging a number of pots and boilers over the flues proceeding from a single fire; and the method of roasting meats in ovens of sheet iron stoves without their acquiring a disagreeable taste, a gentle current of air being allowed to circulate through the ovens.—The stoves of the north of Europe, already referred to as massive structures, are variously built of brickwork and pottery, and sometimes faced with porcelain. They stand upon a platform raised a little above the floor, with a fireplace in the bottom, and at intervals of a few inches horizontal partitions or floors extending nearly across the interior, the openings alternating with each one from one side to the other of the stove. The most elaborate of them are tower-like structures of pure white porcelain, rising one story above another, and finished with various architectural ornaments; sometimes surmounted with classic figures of great beauty, and furnished with brass doors that are kept as bright as gold. The walls are made very thick with brick, and the tiles that form the outside are backed with a sort of earthenware box filled with mortar, and stuck upon the brickwork by iron hooks or pins set in the joints for this purpose. The object of this is to present a heavy mass for receiving and gradually giving out the heat. After the fire has been well kindled, the aperture below for the admission of air is closed, and the door above the fire is opened. This is to check too rapid combustion; and when the fire is at the hottest this door is closed, and also the aperture into the chimney. Thus regulated, these great stoves are commonly kept sufficiently hot during 24 hours by a single feeding of the fire. Some of them are constructed with ovens and with receptacles for boiling. The fireplace is sometimes on the back of the stove, opening into an adjoining apartment. Owing to the material, and moderate heat of the outside, the air is not unpleasantly affected by the burning of any floating particles. Where these stoves are used, all access of air into the room is carefully prevented by tight doors and double windows, and the closing of all crevices. In Germany cast iron stoves are used to some extent, which are provided with tortuous smoke flues, sometimes rising above the stove on each side, and meeting in an arch form before connecting with the chimney flue.—Stoves in the United States are used of the greatest diversity of forms, of cast iron, of sheet iron, and sometimes of soapstone; and those of iron are commonly lined with fire brick specially adapted to their shapes, which not only increases the durability of the stoves, but prevents the iron from being overheated and disagreeably affecting the atmosphere. The stoves are not merely designed for

warming apartments, but are also made for cooking purposes, either with wood or anthracite for fuel. When made of brickwork and iron plates and permanently set, the apparatus is called a cooking range. The manufacture of stoves is a very important branch of industry, and is carried on upon an immense scale in many places. In Albany, N. Y., as stated in the article *FOUNDREY*, nearly 200,000 stoves are annually produced. A large proportion of these are cooking stoves of a great variety of patterns, made of the best mixtures of cast iron, in thin plates, the corresponding parts in all stoves of the same pattern being exact duplicates. These stoves are provided with boilers, kettles, and all necessary cooking utensils. Airtight stoves were introduced not many years since, and have been very generally used for warming rooms, in the country especially, notwithstanding the charge brought against them of vitiating the air by reason of their obstructed draught. They have also in a few instances been the cause of explosions through sudden admission of air to the gases generated by the combustion and pent up in the tight receptacle. Stoves heated by jets of burning gas have recently come into use for warming rooms, and also for cooking. (See *GAS*, vol. viii. p. 101.)

STOW, BARON, D.D., an American clergyman, born in Croydon, Sullivan co., N. H., June 16, 1801. He was graduated at Columbian college, D. C., in 1825, and for the next two years was editor of the "Columbian Star," a religious newspaper published in Washington. On Oct. 24, 1827, he was ordained pastor of a Baptist church in Portsmouth, N. H., and in 1832 became pastor of the Baldwin place Baptist church in Boston, and afterward of the Rowe street church. He was recording secretary of the board of the general missionary convention, afterward merged in the American Baptist missionary union, from 1838 to 1846; he has served 27 years on its executive committee, and in 1835, 1841, and 1858 was elected its corresponding secretary, but in each case declined from a preference for the pastoral work. Dr. Stow is president of the trustees of the Newton theological institution, and a member of the board of fellows of Brown university and of the board of overseers of Harvard university. In 1840-'41 he made the tour of Europe, and in 1859 he spent some time in Great Britain. His published works, apart from occasional sermons, numerous articles in reviews and periodicals, introductions to books by other authors, &c., are: "Daily Manna for Christian Pilgrims" (Boston, 1848); "Christian Brotherhood," "The Psalmist," by Dr. Stow and the Rev. S. F. Smith (1849); "First Things, or Development of Church Life" (1859); "The Whole Family in Heaven and Earth" (1860); "History of the Danish Mission on the Coast of Coromandel," "Memoir of Harriet Dow," "Question Book of Christian Doctrine" (1848); and "History of the English Baptist Mission to India" (Philadelphia).

STOW, JOHN, an English antiquary and annalist, born in London in 1595, died in 1605. He was bred a tailor, and in 1560 devoted himself to the study of the antiquities of English history, but was occasionally obliged to return to his trade to obtain a subsistence, until he was assisted by Dr. Parker, archbishop of Canterbury. Stow made an extensive collection of papers, and, as many of them were Catholic records, they were thought suspicious, and he was cited before an ecclesiastical commission on charges preferred by his own brother; but upon trial he was acquitted of any dangerous attempt. In his old age he was in want, and in 1603 received from James I. a brief by which he was authorized to collect in churches the benefactions of the well disposed. His works are: a "Summary of the Chronicles of England" (8vo., 1561); the "Survey of London" (4to., 1598); and "Flores Historiarum; or Annals of this Kingdom, from the Time of the Ancient Britons to his Own." The folio volume entitled "Stow's Chronicle" was published after his death. The "Summary" concludes with 1560, and the "Flores Historiarum" is only an extensive amplification of the same work; and even this formed but part of a projected "far longer work" for which Stow had accumulated materials.

STOWE, CALVIN ELLIS, D.D., an American clergyman, born at Natick, Mass., April 6, 1802. He was graduated at Bowdoin college in 1824, and, after a year's service as tutor and librarian, entered Andover theological seminary in 1825, and spent two years after completing his studies there in assisting Prof. Stuart, acting at the same time as assistant editor of the "Boston Recorder." In 1830 he was inaugurated as professor of languages in Dartmouth college, and in 1838 became professor of biblical literature in Lane seminary, Cincinnati. Here, in addition to his regular duties, he aided in laying the foundations of the present public school system of Ohio, lecturing and writing on the subject with great effect. In May, 1836, he visited Europe to procure a library for Lane seminary, and to examine, in behalf of the state of Ohio, the public school system of Prussia and some of the other German states. On his return, the next year, he published his report on "Elementary Education in Europe," which was distributed in every district of Ohio by the legislature of that state, and republished and circulated in 6 or 7 other states. He subsequently published reports on the "Education of Immigrants," on "The Course of Instruction in the Primary Schools of Prussia," and on "Elementary Instruction in Prussia." In 1850 he accepted an appointment as divinity professor at Bowdoin college, and in 1852 as professor of sacred literature in Andover theological seminary, which latter he still holds.—HARRIET ELIZABETH BEECHER, an American authoress, wife of the preceding, and daughter of the Rev. Lyman Beecher, D.D., born in Litchfield, Conn., June 15, 1812. At the age of 15 she

was associated with her sister Catharine as principal of a female seminary at Hartford, and in 1838 accompanied her father, who had been elected president of Lane theological seminary, to Cincinnati. She was married in 1836, and removed from Cincinnati with her husband in 1850. She had previously written frequently for periodicals, and published a small volume of sketches entitled "The Mayflower," and several Sunday school books. In 1851-'2 her novel of "Uncle Tom's Cabin" was furnished in weekly chapters to the "National Era," an anti-slavery newspaper of Washington, D. C. On its completion it was published in 2 vols. 12mo. (Boston, 1852), and met with extraordinary success; no work of fiction in the English language ever had a circulation at all comparable to it. In the United States 4 different editions were published, one illustrated and one in German, and not far from 400,000 copies were sold. In England, not being protected by copyright, editions were issued at all prices from 6d. to 10s., and more than 500,000 copies were sold. It was translated into every language of Europe, and several of those of Asia, including Arabic and Armenian; and in many of these, as in the German, French, Italian, Welsh, Wallachian, and Russian, there were from 2 to 12 different translations. It was dramatized in a great number of versions, and acted at almost every theatre in Europe and America. The British museum has a long shelf filled with its different translations, editions, and versions. The truth of some of her statements respecting slavery having been called in question, she published in 1853 a "Key to Uncle Tom's Cabin," verifying them by official and other authentic documents. In 1853 Mrs. Stowe visited Europe, and was warmly welcomed. Several of the English publishers of "Uncle Tom" offered her a copyright compensation, and she received numerous testimonials from the readers of that work. On her return she published "Sunny Memories of Foreign Lands" (2 vols. 12mo., Boston, 1854) and a new and enlarged edition of her "Mayflower." After a second European tour she published "Dred, a Tale of the Dismal Swamp" (1856). "The Minister's Wooing" (12mo., Boston, 1859), a fiction portraying New England life in the latter part of the 18th century, originally appeared serially in the "Atlantic Monthly" magazine (Boston); and another from her pen entitled "Agnes of Sorrento" is now (1862) in course of publication in the same work, beside one entitled "The Pearl of Orr's Island" in the "Independent" newspaper (New York), to which she has been a contributor since 1848.

STOWELL, WILLIAM SCOTT, baron, an English jurist, born in Heworth, Durham, whither his family had fled before the advancing army of the young pretender, Oct. 17, 1745, died Jan. 28, 1836. He was the eldest son of William Scott, a coal merchant at Newcastle-upon-Tyne, and with his brother John, afterward earl of Eldon, received his early education

at the Newcastle grammar school. Having, through the accident of his birth in Heworth, obtained a Durham scholarship at Corpus Christi college, Oxford, he took his bachelor's degree there in 1764, was elected a fellow of University college, and soon after a college tutor. In 1774 he became Camden professor of ancient history in the university, in which capacity he delivered a course of lectures which greatly enhanced his previously high reputation for scholarship. He was in the latter part of 1779 admitted at doctors' commons into the faculty of advocates, and in Feb. 1780, was called to the bar. He readily adapted himself to the practice of the ecclesiastical courts, while an early association at Newcastle with shipping interests suggested the admiralty courts as a field of labor. He accordingly made a speciality of these branches of his profession, and in a few years had obtained so great a reputation as to complain of being "exceedingly oppressed with business." Within a few years he was appointed successively registrar of the court of faculties, judge of the consistory court, vicar-general of the archbishop of Canterbury, and advocate-general. In 1798 he was made judge of the high court of admiralty, the highest honor attainable in his profession, outside of the courts of law and equity. This office he occupied for nearly 30 years, with a reputation surpassing that of any other incumbent, and his decisions are unhesitatingly accepted as law. He entered public life in 1784 as member of parliament for Downton, but was unseated on petition. He subsequently, however, represented this borough for several years, and in 1801 was elected one of the members for the university of Oxford, which constituency he represented until 1821, when he was created Baron Stowell of Stowell Park. He was, like his brother Lord Eldon, strongly conservative, but took no active part in politics. In private society he was noted for his brilliant conversational powers, his wit and polished manners; and, in the latter part of his life, for his gluttony and excessive avarice. It is said that his refusal to allow his only son a sufficient sum to marry drove the latter to intemperance. He died two months before his father, whose title expired with him, and whose immense wealth was divided among collateral relations. Lord Stowell's judgments in the admiralty court, reported by Dr. Dodson, were revised by himself, and, in the words of Lord Brougham, "should form part of every classical library of English eloquence or even of national history."

STRABO, a Greek geographer, born at Amasia, in Pontus, Asia Minor, about 54 B. C., died about A. D. 24. He studied rhetoric under Aristodemus at Nysa; was a pupil at Amisus in Pontus of Tyrannio the grammarian, and at Seleucia in Cilicia of Xenarchus, a peripatetic philosopher. At Alexandria in Egypt he studied under Boëthius of Sidon, also a peripatetic; and at Tarsus under Athenodorus, a stoic. He travelled in Syria, Palestine, Egypt, Crete, northern Greece, a part of Peloponnesus, and

Italy, and it is probable that he spent a considerable time at Rome. He wrote some "Historical Memoirs" (*Υπομνηματα Ιστορικα*), which are lost, and his "Geography." This work is divided into 17 books; the first 2 treat of cosmography, or the description of the earth in general, and the other 15 give accounts of particular countries, 8 of them treating of Europe, 6 of Asia, and 1 of Africa. The origin of peoples, their migrations, the foundation of cities, and establishment of empires, are considered fully, and often very minutely. For his descriptions of places Strabo relied mostly upon his own observations, and speaks only in a general manner of those places which he had not himself seen. His accuracy in many of his statements is doubted, yet his work is one of the most valuable that have come down from antiquity. Among the best editions of Strabo are those of Casaubon (1597) and Kramer (1844-'52). There is an English translation by Falconer and Hamilton (8 vols., 1854-'7).

STRADA, FAMILIANO, an Italian author, born in Rome in 1572, died there in 1649. He entered the order of Jesuits, became professor of rhetoric in the Gregorian college at Rome, and there spent the greater part of his life. He wrote *Prohusiones Academica*, a series of essays upon rhetoric and literature; but his most important work is the history of the Spanish war in the Netherlands, entitled *De Bello Belgico ab Eusebio Caroli V. ad Annum 1590* (fol., Rome, 1640-'47), translated by Sir R. Stapylton (fol., London, 1650).

STRADELLA, ALESSANDRO, an Italian musician and composer, born in Naples about 1645, assassinated in Genoa in 1678. He was regarded as the first musician of his time, and it is related that his skill was such that a jealous rival of his in an affair of gallantry was disarmed and became his friend on hearing him sing in his oratorio *Di S. Giovanni Battista*. This was in 1676. Two years later, however, he perished.

STRAFFORD, THOMAS WENTWORTH, earl of, an English statesman, born in London in 1598, executed on Tower hill, May 12, 1641. He was educated at St. John's college, Cambridge, travelled abroad, became at the age of 21, upon the death of his father, the possessor of very considerable family estates, and in 1614 was elected to parliament for the county of York. His prepossessions on the side of popular rights, and his eloquence in opposition to the king, marked him as a leader of the commons to be dreaded, and if possible to be silenced, by the court party. It is a memorable coincidence that Hampden and Wentworth attained to political prominence at the same time. Both were among the richest and most powerful commonsers of England, and both were equally distinguished by force of character and talent. "Hampden," says Lord Macaulay, "had more judgment and sagacity than Wentworth; but no orator of the period equalled Wentworth in force and brilliancy of expression." In 1626 both were committed to prison by the

king, for refusing to pay taxes illegally levied. Here their paths separated. The king saw the necessity of corrupting, if possible, the chiefs of his enemies. Hampden had already turned away with contempt from aristocratic honors, the acceptance of which at that mercenary period he felt would be degrading. Sir Thomas Wentworth, however, yielded to the seduction, and is branded in history as the first Englishman to whom a peerage was not an addition of honor. He was the first and the greatest upon the list which soon grew rapidly. As late as 1628 Wentworth was still an unshaken opponent of the court, and had become one of the most conspicuous advocates of the "Petition of Right." High terms were offered to him. He was first gained over by the offer of a peerage. He was first created Baron, and soon after Viscount Wentworth. He abandoned his old associates, and ever after hated them with the hatred of a renegade. "Whipped," he said, should Hampden be. "I would have him whipped into his right senses; and if the rod be so used that it smart not, I should be the more sorry." Pym, who foresaw in Wentworth an English Richelieu, uttered his ominous threat: "You have left us, but while your head is on your shoulders I shall not leave you." The viscount was soon elevated to higher title and to great office. He became earl of Strafford, lord lieutenant of Ireland, and president of the council of the north; and although, after the assassination of the duke of Buckingham, Charles appears to have been his own prime minister, Strafford was his chief councillor. The earl perfectly understood the feelings, resources, and policy of the man whom he had deserted, and was able to lay his schemes with a depth which came near confounding the tactics of the skilful leaders of the parliament. His object was to make his master an absolute monarch; and it was his boast that in Ireland, of which he was the viceroy, he succeeded. The king was "as absolute" in that island, to use his own words, "as any prince in the whole world." The skill and the daring energy of Strafford have commanded the wonder of all historians; and had his object been for the good of his country and of his kind, history might record his name with unqualified admiration. But there is scarcely a virtue, in the strict sense of the term, to redeem the character of this "great, brave, bad man." Government by the sword was his favorite scheme. In Ireland his executive administration set at naught the courts of law. No man left the island without his permission; vast monopolies were established for the benefit of his partisans; taxes were laid at his will, and levied by military force; and men who chanced to offend the powerful earl were condemned by his minions to death. Arbitrary and tyrannical however as Strafford was, it is universally conceded that he greatly improved the general condition of the people of Ireland. His viceroyalty was several times interrupted by the calls of the

king to his counsels, when trouble sorely beset him. Charles put him in command of the army against the insurgent Scots, before whom the royal troops fled panic-struck, after the rout at Newburn (Aug. 28, 1640); and Strafford, possessing more vigor of mind than the king or any of the council, advised strenuously against accepting the terms which the insurgents would impose. But Charles, in despair of being able to stem the torrent, determined to yield to it. The king saw himself moreover compelled to summon a parliament, and Strafford, dreading the consequences, besought his master to allow him to return to Ireland. Charles, however, desirous of profiting in the emergency by his great talents, and pledging his royal word that "not a hair of his head should be touched by parliament," prevailed upon the unhappy minister to brave the issue. The assembly met on Nov. 8, 1640. On the 18th Pym, true to his word, appeared on the part of the commons at the bar of the house of lords, with the message of impeachment. The earl, who had just taken his seat, was immediately sent to the tower. The articles of impeachment, at first 9 in number, were afterward increased to 28, with a view to convict the accused of an attempt to subvert the fundamental law. The impeachment of Strafford was the first retributive blow dealt upon the king. The guilt of the minister is placed beyond a doubt by evidence which has come to light since his death; but it was never proven by his accusers, and his defence was so strong, his abilities and presence of mind, his shrewdness, consistency, and eloquence, his judgment and composure so overwhelming, that the house abandoned the original impeachment, and had recourse to other means of bringing him to his end, which were wholly unjustifiable. A bill of attainder, brought into the lower house, was passed by a great majority. The lords, in a panic, complied; and the bill was sent to Charles for his approval. The king had striven to keep his word that not a hair of his servant's head should be in danger. In fearful distress, with popular violence impending in case of refusing the warrant for the execution, the unhappy monarch saw no resource, no security; and Strafford, learning the truth, wrote a letter with much appearance of magnanimity, advising and urging the irresolute king, for the sake of the public peace, to sacrifice a life which would be resigned cheerfully to a master who had bestowed such "exceeding favors." Such was the spirit of the earl's last counsel to the king. Historians, however, refuse to ascribe the proceeding to generosity or disinterestedness. He may or may not have been, as Hume suggests, actuated by the hope of what must appear to every generous mind would be the effect upon the king, viz., to resolve, after such an act, at every hazard to rescue his best friend. Charles, however, was not thus affected. He acceded; and Strafford, lifting his eyes to heaven, as if doubting his senses, gave impulsive yet gentle

utterance to his emotion. "Put not your faith in princes," he said solemnly, as though the sacred volume opened now for his teaching, "nor in the sons of men; for in them there is no salvation." The king lived to be far more unhappy than the friend whom he had abandoned. The remainder of his life was haunted by strong compunction for this act; and even at his own fatal end, the memory of this guilt came upon him with poignant remorse. The earl, on the other hand, laid his head upon the block as though his career had been that of a life-long benefactor of his kind. Nothing in the history of executions has ever surpassed the manliness of his conduct from the hour of his impeachment. He moved from his prison to Tower hill with an air of dignity surpassing even his ordinary noble aspect. "I lay down my head," said he, after declaring his innocence, "as cheerfully as ever I did when going to repose." His memory remains as one of the most eminent and brilliant personages that have appeared in England; and at this remote day his features on the "living canvas" of Vandyke still awe the beholder, as the haughty earl in life overawed his contemporaries. His stainder was reversed under Charles II. His "Letters and Despatches" were edited by Dr. Knowler (2 vols. fol., London, 1789).

STRALSUND, a strongly fortified seaport town of Prussia, in Pomerania, capital of the administrative district of the same name, situated on the strait which separates the island of Rügen from the mainland, in lat. 54° 18' N., long. 13° 6' E., 120 m. N. from Berlin; pop. 20,838. The site of the town is so completely surrounded by water, that it can only be approached by bridges, which connect it with its 8 suburbs on the mainland. Though the town has a gloomy appearance, it is clean and well paved. The principal churches are those of St. Nicholas and St. Mary, the former dating from the 13th century and the latter from the 14th. They are both fine specimens of the pointed style of architecture, and have many valuable paintings. The town hall contains a public library, and the gymnasium has both a museum and library. The manufactures include linen and woollen goods, starch, sugar, tobacco, soap, and leather. Ship building is carried on, and there is an active trade. The chief exports are wheat, malt, timber, wool, and linen. The harbor is large, but shoals prevent vessels drawing more than 15 feet from entering it.—Stralsund was built by Jaromar I., prince of Rügen, about the year 1209, and soon rose to be a place of importance, and became a member of the Hanseatic league. It successfully resisted Wallenstein, who besieged it in 1628, and lost 12,000 men before its walls. The Swedes gained possession of it by the peace of Westphalia, and Frederic William, elector of Brandenburg, captured it from them in 1678, but restored it in the following year. Stralsund surrendered to the Prussian, Danish, and Saxon forces in 1715, but was given back to Sweden in 1720. It was surrendered to the

French in 1807, who destroyed a great part of the fortifications; and by the treaty of Kiel in 1810 it was ceded to Denmark. In 1815 Denmark surrendered it to Prussia.

STRAMONIUM. See DATURA.

STRANGE, SIR ROBERT, an English engraver, born in Pomona, one of the Orkney isles, July 14, 1721, died July 8, 1792. While an apprentice to an engraver in Edinburgh he joined the forces of the young pretender, and after the battle of Culloden was obliged to take refuge for some time in the highlands. Having studied abroad for some years, he settled in 1751 in London, and soon rose to great repute as a historical engraver. During a second visit to the continent in 1760 he executed many admirable plates after the old masters, and was made a member of the academies of Rome, Florence, Bologna, Parma, and Paris. He amassed a fortune by his art, as well as by his shrewdness and judgment as a dealer in pictures. He wrote a "History of the Progress of Engraving," which was never published, and commenced an autobiography, given in the memoir of him by James Dennistoun of Dennistoun (2 vols. 8vo., 1855).

STRASBOURG (Ger. *Strasburg* or *Strassburg*), a town of France, capital of the department of Bas-Rhin, situated on the Ill, a tributary of the Rhine, about a mile from its junction with that river, and 250 m. E. by S. from Paris; pop. in 1856, 77,656. It stands upon level ground, is nearly 6 m. in circuit, and is defended by a wall with bastions, ditches, and outworks, and a strong citadel constructed by Vauban. It is entered by 7 gates, and the Rhine is crossed by a bridge of boats which leads to the fortress of Kehl in Baden. The Ill flows through the town in a N. E. direction, has many branches, and is crossed by several wooden bridges. The streets are generally crooked and narrow, but the principal ones are broad, and there are several fine squares. The houses are well built and rather lofty with steep roofs. The cathedral of Strasbourg is considered one of the finest Gothic buildings in Europe, and its spire is the highest in the world, being 466 feet. It was originally founded in 504, but the edifice was almost completely destroyed by lightning in 1007. The present building was begun in 1015 and completed in 1439. The W. front is richly decorated with sculptures, statues, and bas-reliefs, rises to the height of 280 feet, and has a circular window 48 feet in diameter. The principal dimensions are: extreme length 857 feet, height of ceiling 79 feet, length of transepts 140 feet, and breadth of the nave 85 feet. There are 14 other churches, the most interesting of which are those of St. Stephen, St. Thomas, the Temple Neuf, and St. Pierre le Jeune; and the Jews have a splendid synagogue. The other buildings most worthy of notice are the episcopal palace, prefect's office, town hall, custom house, court house, the public library containing 180,000 volumes, the royal academy, theatre, and picture gallery.

The military establishments are on an extensive scale, and include an arsenal, artillery school, cannon foundry, barracks, and hospital. The manufactures are numerous, and include woolen, linen, and cotton goods, sail cloth, jewelry, clocks and watches, cutlery, hardware and cast iron articles, porcelain, earthenware, soap, leather, straw goods, hosiery, paper, and cards. There are numerous bleachfields, dye works, sugar refineries, breweries, and printing offices; and the town is celebrated for its goose liver pies (*pâtés de foies gras*). The trade of Stratford is extensive, and is greatly facilitated by the navigation of the Rhine.—Strasbourg occupies the site of the ancient Argentoratum, which after the Roman conquest was made a frontier fortress against the Germans. It was a free city of the empire during the middle ages, and was a Protestant city till seized by Louis XIV. in 1681; but although nearly two centuries have since elapsed, it still retains in its appearance, people, and language the general characteristics of a German town. It is one of the strongest of fortresses, having been improved under the direction of Vauban.

STRATFORD DE REDCLIFFE, STRATFORD CANNING, viscount, an English diplomatist, born in London, Jan. 6, 1788. He is a cousin of George Canning, and was educated at Eton, and at King's college, Cambridge. He commenced his public career in 1807 as *précis* writer in the foreign office, and in 1808 was appointed secretary to the special mission at Constantinople under Sir Robert Adair, whom he subsequently succeeded as minister plenipotentiary. In 1814 he was despatched in the same capacity to Switzerland, and assisted in framing the treaty which united the 19 cantons in the Helvetic confederation; and in 1820 he was appointed minister at Washington, where he remained 8 years. Between 1824 and 1829 he participated at St. Petersburg and Constantinople in the negotiations which led to the recognition of the independence of Greece by England, France, and Russia. In 1831 he was again sent to Constantinople on a special mission, and in the same year he went in a similar capacity to Madrid. For several years he held no public office, though twice offered the governor-generalship of Canada by Lord Melbourne; but upon the accession of Sir Robert Peel to power in 1841 he was reappointed minister to Constantinople, where he remained until relieved by Sir Henry Bulwer in 1853. In April, 1852, he was raised to the peerage, having previously sat in the house of commons for Old Sarum, Stockbridge, and Lynn-Regis. His long residence in Constantinople, and his familiarity with eastern politics, have given him an influence with the sultan enjoyed by no previous English ambassador. Many important reforms in Turkey, particularly those affecting the condition of the Christian population, have been attributed to his efforts.

STRATFORD-UPON-AVON, a municipal borough and market town of Warwickshire,

England, situated on the right side of the river Avon, 9 m. S. W. from Warwick, and 96 m. N. W. from London; pop. in 1851, 3,872. Stratford was a place of some consequence as early as the middle of the 8th century, but derives its sole interest at the present day from the fact that it was the birthplace of Shakespeare, his abode in youth and age, and the place of his death, and is the present depository of his remains. A part of the ancient house in which he is said to have been born, and of which he retained the possession at the time of his death, is still standing in Henley street, and has recently been purchased for the nation by subscription at a cost of about £4,000. The chamber of his birth and other parts of the building supposed to be associated with his history are preserved with great care, and, so far as possible, in the same condition as in the poet's lifetime. Measures have recently been taken to raise a fund for the purpose of keeping the building in repair. The church, a handsome cruciform structure with a fine tower and spire, situated near the river, contains his remains and those of his wife, which are buried in the chancel on the north side, and in the vicinity of a monument, the distinguishing feature of which is the celebrated portrait bust of Shakespeare in marble. This edifice was thoroughly restored in 1840, and is now one of the best preserved ecclesiastical buildings in the country. The grammar school, in which, according to tradition, Shakespeare was educated, is established in the upper part of the ancient guildhall; and among the places in the immediate neighborhood traditionally associated with incidents of his youth are the cottage of his wife, Anne Hathaway, in the adjoining parish of Shottery, and Charlecote house, the seat of the Lucys, a few miles higher up the Avon. In 1769 a Shakespeare "jubilee" was celebrated in Stratford under the direction of Garrick, on which occasion the present town hall, which contains a statue of Shakespeare, was erected. Recently a triennial commemorative festival was proposed, but has not been observed with any regularity. New Place, the residence in which Shakespeare passed his latter years and where he died, came about the middle of the last century into the possession of a clergyman, the Rev. Francis Gastrell, who, after having in 1756 cut down a mulberry tree venerated by the townspeople on account of the tradition that Shakespeare had planted it, destroyed the house itself in 1759. Part of the garden belonging to New Place, however, still remains, and was secured to the possession of the public in perpetuity by subscription in 1861.

STRAUSS, DAVID FRIEDRICH, a German theologian, born in Ludwigsburg, Würtemberg, Jan. 27, 1808. He was educated at Blaubeuren and Tübingen, was engaged as curate in 1830 and as professor at Maulbronn in 1831, and in 1832 became *Repetent* in the theological seminary at Tübingen, where he also lectured on the Hege-

lian philosophy in the university. His name was unknown when he published *Das Leben Jesu* (3 vols., Tübingen, 1835; 4th ed., 1840; translated by Marian Evans, 8 vols., London, 1846, 1 vol., New York, 1850), a work remarkable for its boldness and acuteness, which more than any other engaged the attention of Protestant theologians for many years. Its design was to establish for Christianity a mythological instead of historical basis, to resolve the Gospels into popular legends, and the miracles into significant poetry. It supposed the existence of Jesus, an exemplary and reformatory rabbi of Galilee; that he lived and died an enthusiastic and admired teacher and innovator; that after his death many marvellous incidents concerning him gradually gained currency; that some of these were exaggerations of actual events, and others symbolical forms in which his disciples clothed his doctrines and precepts; that these wonderful narratives were not designed by single persons, but were the spontaneous outgrowth of poetical and philosophical tendencies in the early church; that they circulated orally for half a century or more, being constantly magnified and multiplied; and that from this cluster of myths, this mass of legendary and poetical lore, various compilations were then made, of which there have come down to us the 4 canonical and several apocryphal Gospels. Having thus attempted to resolve the historic Christ into a myth, the second part of the work proceeds by means of the Hegelian philosophy to assign a new meaning to the New Testament. The career of Christ symbolizes the moral history of mankind. Humanity is God manifest in the flesh, sinless, working miracles, dying, rising, and ascending to heaven. Thus the narrative applies not to an individual, but to the race; the dogmas are true, though the history is false; and the early Christians unconsciously gave a concrete development to Hegelian philosophemes. Replies to this work on exegetical, historical, and philosophical grounds immediately appeared in Germany, and soon after in France, England, and America. It was controverted by the most prominent biblical and patristic scholars in those countries. The author was deprived of his position as *Repetent*, though he urged that he believed as an idea every thing which others believed as history, and became a teacher at Ludwigsburg, and after 1836 in Stuttgart. In Berlin the ministry of public worship asked the advice of Neander whether to suppress the book. He replied that it contained views which left no basis for historical Christianity, but that it was written with scientific earnestness, and ought to be met and answered only in the forum of science. In 1837 Strauss replied to his critics by 3 volumes of *Streitschriften*, and in 1838 by *Zwei friedliche Blätter*, but subsequently availed himself of the new editions of his work to controvert his opponents. In 1839 he was invited, after violent opposition, to the university of

Zürich as professor of dogmatics and church history. In this position he published *Charakteristiken und Kritiken* (Leipzig, 1839), a collection of essays, and his second important work, *Die christliche Glaubenslehre in ihrer geschichtlichen Entwicklung und in ihrem Kampfe mit der modernen Wissenschaft* (2 vols., Tübingen, 1840-'41), a historico-critical treatise on Christian dogmatics. His next publication was *Der Romantiker auf dem Throne der Cäsaren* (Mannheim, 1847), a satirical parallel between the restoration of heathenism by Julian, and the restoration of Protestant orthodoxy by the king of Prussia. In 1848 he was the unsuccessful candidate of his native town for the parliament at Frankfurt; and the public addresses which he delivered at this time were collected under the title, *Sechs theologisch-politische Volkreden* (Stuttgart, 1848). The same constituency however elected him nearly unanimously to the diet of Würtemberg, where he astonished all parties by ranging himself among the conservatives. He has since published a series of biographical studies: *Schubart's Leben in seinen Briefen* (1849); *Christian Märklin, ein Lebens- und Charakterbild der Gegenwart* (1851); *Leben und Schriften Nikolaus Frischlin's* (1855); and *Ulrich von Hutten* (2 vols., 1858).

STRAUSS, GERHARD FRIEDRICH ABRAHAM, a German divine, born at Iserlohn, Sept. 24, 1786. He was educated at Halle and Heidelberg, became a pastor at Ronsdorf in 1809 and at Elberfeld in 1814, and in 1822 was invited to Berlin as preacher to the court and as professor in the university. Among his publications are: *Glockentöne, oder Erinnerungen aus dem Leben eines jungen Predigers* (3 vols., Elberfeld, 1812-'20; 7th ed., 1840); *Helon's Wallfahrt nach Jerusalem, 109 Jahre vor der Geburt unsers Herrn* (4 vols., Elberfeld, 1820-'28); and several collections of sermons.

STRAUSS, JOHANN, a German composer, born in Vienna, March 14, 1804, died there, Sept. 15, 1849. At 19 years of age he entered the orchestra of Lanner, a popular composer of dance music, stimulated by whose success he attempted a similar class of compositions. He soon organized a new band, which under his direction became famous for the brilliancy and perfection with which it executed the lighter forms of music; and in like manner his waltzes and dances, remarkable for their adaptation to the purposes intended, became celebrated and popular all over Europe.

STRAW, the stem or stalk of plants of the natural order *gramineæ* or grasses, commonly understood as limited to those which produce the edible grains. It is applied to a variety of useful purposes after the grain has been removed by threshing or by clipping off the heads. It consists of a jointed tube of woody fibre, containing in its outer portion especially much silica, combined in part with potash and soda; and the same alkalies also exist in the ash, in the form of chlorides and sulphates. The return of these salts to the soil cannot fail

to be beneficial to new crops, and straw is advantageously used by farmers as a fertilizer; an excellent mode of preparing it for this use is to cause it to absorb liquid manures and then expose it in compost heaps to ferment. It is largely consumed upon farms for littering animals, and is made use of as a material for beds. It is also used, by the method called thatching, as a covering of roofs of buildings, and for protecting stacks of hay from the weather. Being while dry a poor conductor of heat, it serves to protect delicate plants and trees from frost, and it is sometimes made into ropes for particular modes of applying it to this use. In the West Indies it is the common material of the large pack saddles; and in the United States and in Europe it is frequently employed for the collars of draught horses. It is largely used for matting for floors, and in the East Indies is even woven into sails for vessels. In the arts, the principal uses of straw are for the manufacture of hats and bonnets, and to some extent of paper and of ornamental baskets. The Japanese cover boxes of various kinds with split straws, laying them close together so as to present a smooth flat surface, of delicate satin lustre.—The plaiting of straws for hats and bonnets is of comparatively modern invention, not being traced back beyond the commencement of the 17th century, when, as narrated in Coryat's "Crudities," "delicate strawen hats" were worn by men and women in many places in Piedmont. As some of them were said to have at least 100 seams, it is probable the plaiting was at that time very fine. In England the manufacture was not introduced before the next century. Some account of it is given in the article HAT, vol. viii. p. 764. In Tuscany, where this work, which is known as the Leghorn plait, is carried to the highest perfection, a variety of bearded wheat (*tritium turgidum*) is grown solely for the straw, and the upper joint is selected as the best for plaiting. The straw is small, owing in part to the seed having been sown broadcast, and partly to the plant not being allowed to attain to maturity. It is spread on the ground to dry in the sun, and is further dried when tied in bundles and stacked. It is then again spread out to be bleached by the sun and dew, being frequently turned while thus exposed. The lower joint is then pulled off, and the upper portions are steamed and fumigated with sulphur. Thus prepared, the straw is largely exported to England. The best work is done in Tuscany in the spring season. In summer the dust and perspiration affect injuriously the appearance of the straw; and in winter the smokiness of the huts and the difficulties of plaiting the wet straw with cold and benumbed fingers also interfere with the excellence of the work. The hats tarnished in the manufacture from these causes cannot be restored by bleaching or other processes. The Tuscan straw, owing to its small size, may be used without splitting; but the English, to produce as

fine work with their large wheat straws, were obliged to adopt the expedient of splitting the straw into narrow splints or slips. This was first done by knives, and afterward by the machines described in the article HAT. The introduction of this simple process had increased the returns in this branch in 1810 not less than £800,000 or £400,000 annually. The society of arts gave great encouragement to the manufacture, which led to various improvements in the processes. Rye straw was substituted for wheat straw, and the manufacture was extended to the Orkneys, to the climate of which the former variety was better adapted. As the split straw when plaited presents alternately its inner and outer surface, the work lacks that uniformity of appearance produced by the whole straw. To secure this, the plan was devised, in the plait called the "patent Dunstable," of laying two splints with their inner surfaces together, which also increases its durability. The plaits are made of various widths, and by the usual method practised in England they are put together overlapping each other along their edges, and producing little ridges over the whole work; but the Leghorn plait is so made that the edges are joined by being as it were knitted together, so that there is very little waste of material by overlapping and no interruption of the pattern. The pieces are held fast by a thread which is drawn tight and concealed in the work. The first straw bonnet braided in the United States is said to have been made in 1798 by Miss Betsey Metcalf, afterward Mrs. Baker, of Providence, R. I. It was an imitation of a Dunstable bonnet which she saw in a store in Providence. A facsimile of it, also made by Mrs. Baker, is preserved in the collection of the Rhode Island society for the encouragement of domestic industry, and is regarded with no little interest as connected with the first step in a great branch of industry, which in Massachusetts alone is said to employ 10,000 persons and to produce 6,000,000 hats and bonnets annually. In Philadelphia also the production of straw hats is carried on upon a large scale, and straw braid for the purpose is imported from England, Switzerland, and Tuscany, and coarse straw hats for the southern trade are largely imported there from Canada. One of the largest factories is at Bridgeport, Montgomery co., near Philadelphia. The annual production of Philadelphia has been estimated at over \$600,000, or \$350,000 for hats and \$250,000 for bonnets. Many varieties of plaited work are introduced in hats and bonnets, some distinguished for their extreme fineness, and others for their total disregard of this quality. The styles too are continually changing, and the work is variously modified by the introduction into it of other substances, as lace, mohair, whalebone, &c. Straw is bleached with sulphurous acid, as described in HAT, and is dyed of various colors. A boiling hot solution of indigo in sulphuric acid gives a blue color; a decoction of turme-

ric a yellow color. Cochineal, salt of tin, and tartar are employed for producing a red; and various other dye stuffs are employed.—In Peru, Brazil, and other parts of South America, and in Central America, a straw is obtained from plants of the genus *bambusa*, which resemble in their growth tufts of marsh reeds, and are of a delicate green color. This is largely applied to the manufacture of hats and cigar cases; the former are distinguished as the most durable of all straw hats, and are known by the name of Panama hats, from the principal port of their shipment. They are manufactured by the Indians, whole colonies of whom, as that of the Moyobamba on the Amazon to the north of Lower Peru, are wholly devoted to this employment. The plants are cut before their full development, and are steeped in hot water until they become white. After being dried by artificial heat, they are exposed to the sun several days to bleach, and are then distributed throughout the districts where the manufacture is carried on. The men, women, and children engaged in it are described as sitting outside their cottages, smoking cigarettes, and plaiting the straw upon a block of wood which they hold between their knees. Commencing at the centre, they continue the plaiting in a spiral, finishing an ordinary hat in 2 or 3 days; but the finest hats occupy several months to complete them, and require especial care in the selection of the straw and the plaiting. The remarkable strength and flexibility of the straw admit of the hats being rolled up in small packages, so that they may be carried in the pocket without injury; and they are so closely plaited as to be water-proof. Their price varies with the quality from \$2 or less to more than \$100 each. The trade with the Indians is much impeded by their slow methods of dealing, the sale of each hat being a separate bargain involving long delays, so that a whole day is often occupied in buying 20 of them. The annual exports of these hats from Panama have been estimated at 60,000 to 80,000, and from Moyobamba at over 10,000.—The application of straw to the manufacture of paper has been noticed in the article PAPER, vol. xii. p. 785. In England it is thus employed mixed with rag pulp in a number of paper mills, and is said to produce a pretty good article for newspapers. By a late German invention a good paper pulp is said to be prepared from straw alone by the following process: The straw is steeped entire in soft water at a temperature of 55° to 85° according to the season of the year. Active fermentation takes place, and after steeping 60 hours, the water is run off and the straw is well washed with a fresh supply. It is then drained, and while still damp it is rolled flat under heavy stones or between rollers, and is then split up into long filaments between other rollers furnished with cutters. These are dried by exposure to the sun and air, and may be partially bleached by again wetting and drying in the

sun. Various chemical preparations, as a solution of the hypochloride of lime, may be used to perfect the bleaching, when they are treated either with alkaline solutions or solutions of hypochloride of soda or potash, and after this are steeped several days in other mixtures, from which they are easily converted into pulp.

STRAWBERRY, a well known garden fruit, cultivated under a great many varieties and sub-varieties, bearing distinctive names. From an old custom of laying straw under the ripening fruit, the word strawberry originated, while the generic name of *fragaria* was derived from the Latin *fragrans* on account of its delicious perfume. According to Linnæus there are but two species, and more modern botanists are inclined to the same opinion, though many writers undertake to make out several. They are both found in America and in Europe, and are the common (*F. vesca*), with thin, plicate, light green leaves, hairy beneath, the sepals reflexed and the achenes or seeds on the surface of the fruit; and the wild (*F. Virginiana*), having smooth dark green leaves, the sepals spreading, and the seeds imbedded in the fruit. Morphologically the strawberry fruit is in reality what are commonly regarded as the seeds, the edible part being only an enlarged receptacle of the flower. Mr. T. A. Knight, in the "London Horticultural Transactions," vol. iii. p. 207, decides from many experiments that 3 alleged species, *grandiflora* from Surinam, *Chiloensis* from Chili, and *Virginiana* from North America, are no more than varieties of one plant; and the same may perhaps be proved as regards certain other species which might have originated from the *vesca* or wood strawberry. Long cultivation has effected many changes in the habit and form of foliage and fruit, and even some of these might occur naturally. Horticulturists have however grouped the hybrid kinds into 7 classes, viz.: from *F. vesca* the alpine, from its variety *elatior* the hantbois, and from its variety *collina* the green-fruited or green pine; while from *F. Virginiana* and its varieties have sprung the scarlet, black, or brown fruited, the common pine, Wilmot's superb, Hovey's seedling, and the like, all the very largest sized berries.—The cultivation of the strawberry has given rise to hybrid sorts of remarkable firmness of flesh, juiciness, richness of flavor, and magnitude of fruit. Generally speaking, the soil for successful culture should be deep, rich, and well pulverized, the plants set in rows 18 inches apart, and the plantation renewed every year or two. Particular kinds are found to do better in certain districts than in others; yet care in planting, freedom from weeds, and a good soil are the principal requisites. Certain sorts become defective in perfect stamens, and such as are stamiferous should be partially planted with them. The commercial value of the strawberry crops in favorable seasons renders the raising of this fruit very profitable.

STRAYS. See ESTRAYS.

STREET, ALFRED BILLINGS, an American poet, born in Poughkeepsie, N. Y., Dec. 18, 1811. At 14 years of age he removed with his father to Monticello in Sullivan co., where he was admitted to the bar, and for several years practised law. In 1839 he settled in Albany, where he has since resided, and where for a number of years he has held the position of state librarian. He commenced his literary career as a contributor of verses to the magazines, and in 1840 delivered a poem on "Nature" before the Euglossian society of Geneva college; and he has since delivered several poems before different colleges in New York, and one before Yale college. In 1842 appeared his first volume of poems, under the title of "The Burning of Schenectady, and other Poems," followed in 1844 by a 2d collection, "Drawings and Tintings," and in 1846 by a complete collection of his fugitive poems (8vo., New York). In 1849 appeared in London and New York his longest poem, "Frontenac," consisting of 7,000 lines. In 1860 he published two prose volumes: "The Council of Revision" (8vo.), containing the vetoes of the council, a history of the supreme, chancery, and admiralty courts of New York, and biographical sketches of its governors and judges from 1777 to 1821; and "Woods and Waters, or the Saranacs and Racket," a description of a tour in the great wilderness of northern New York. Several of his poems have been translated into German.

STRELITZ. See MECKLENBURG.

STRELITZES. See GUARDS, vol. viii. p. 537.

STRENGTH OF MATERIALS, a general expression in the constructive arts for the measure of capacity of resistance, possessed by solid masses or pieces of various kinds, to any cause tending to produce in them a permanent and disabling change of form or positive fracture. (See the articles **ARCH**, **BEAM**, **BRIDGE**, and **CARPENTRY**.) The present notice will be devoted mainly to the general principles of the subject. The materials employed in construction are chiefly of 4 kinds: 1, timber; 2, rock (or natural stones); 3, bricks, concretes, &c. (artificial stones); 4, metals, especially iron. All these resist fracture in whatever way; but the capability of resistance in a given case varies with many particulars, but chiefly the following: 1, the nature of the material and its quality; 2, the shape and dimensions of the piece used; 3, the manner of support from other parts; 4, the kind and direction of the force tending to produce rupture. Materials of all kinds owe their strength to the action of those forces residing in and about the molecules of bodies (the molecular forces), but mainly as well as most obviously to that one of these known as cohesion, the direct result of the operation of which among the particles and within the fibres of any mass is to impart to it the property of toughness or tenacity. Certain modified results of cohesion, as hardness, stiffness, and elasticity, are also important elements; and the strength is rather in the ratio

of the toughness and stiffness combined. Since the quality of the same kind of material must vary with a great variety of circumstances, some of them not readily cognizable by the experimenter or the engineer, it will follow that there must be a corresponding variation in the results as to strength obtained by different observers; that the numbers employed to express the strength afford at best but approximations; and that in practice the load or pressure allowed must fall considerably within even these limits. A timber or piece of other kind may be subjected to strain or fracture in 4 ways: 1. It may be stretched, pulled, or torn asunder, as in case of ropes, tie-beams, &c. This is called direct pull, tensile strain, or tension; and resistance to it, tensile strength. 2. It may be crushed in the direction of the length, as in columns and truss beams. This is direct thrust, direct pressure, or compression; and resistance to it, the crushing strength. 3. It may be bent or broken across by a force perpendicular or oblique to its length, as in common beams and joists. This is transverse strain, or flexion; resistance to it is the transverse strength. 4. It may be twisted or wrenched off, in a direction about its axis, as in case where the shaft or journal of a turning wheel is suddenly arrested in its movement. This is torsion; resistance to it, the torsional strength. A 5th sort is sometimes added, namely, detrusive strength, or that consisting in resistance to the sliding of the particles or fibres upon each other; hence, opposing such applications of force as those made in the operations of punching and shearing. Any bending or breaking pressure is a stress; its effect on the piece, a strain. Briefly, then, the strength of a solid piece or body, in any direction, is the total resistance it can oppose to strain in that direction. 1. *Tensile Strength.* A rod, rope, or any body, being pulled or strained in the direction of its length (the form, in these cases, being usually cylindrical or prismatic), its cohesion can come into play only by reason of the opposite end being fixed; and the amount of cohesion excited is a reaction against the pull or strain applied. From these principles it follows that, up to the limit of strength, the amount of cohesion excited in the way of reaction is always exactly equal to the amount of the acting strain, rupture or permanent change following as soon as the latter has passed the limit named; and also, that at every moment the strain and reaction are equal throughout the whole length of the piece acted upon; hence again, that where weight does not (as it must in any hanging rope or piece) come in to modify the result, the piece must, when the limit of strength is exceeded, always part or yield at its weakest portion; and that the tensile strength can never exceed that of such weakest portion. Two fibres of like character, equally stretched, must exhibit double the strength of one. Generalizing this result, we say that the tensile strength of rods, beams,

ropes, wires, or other pieces is, for each material, proportional to the area of the cross section of the piece used. This is, accordingly, also termed the absolute strength. And it is a corollary that, in pieces of like material, having all of them circular or all square cross sections, the tensile strengths are as the squares of the diameters or sides of such sections respectively. But these laws presuppose certain other conditions. 1. The strains must be each in the line of the axis of the piece, or the result is modified by tendency to cleave (in timbers), or by detrusive or transverse strain. 2. The lateral cohesions of the particles or fibres, and the comparative strengths of the several fibres, are supposed to be all equal; but so heterogeneous are most materials employed, that neither of these suppositions can in most instances hold true. When allowance for modifying influences of the kinds now named is made, the laws of tensile strength become safe guides in practice, though the behavior of different materials in yielding to tension may vary considerably. Any material, under a considerable tensile strain, becomes slightly elongated, not returning when the strain is taken off. This result is expressed by saying that the body possesses extensibility. It is doubtful whether in all materials, or in most, a result of this kind can be often or indefinitely repeated. But over this, the body lengthens a little by every pull in consequence of its elasticity; and this effect is not permanent, at least its whole amount is not so; the piece shortens again, when the strain is removed, by quite or nearly the amount of this lengthening. Thirdly, if the body, in addition to these two properties, possess that of ductility, when the limit of its extensibility and elasticity is reached, the particles upon the surface at the weakest point begin to slip upon each other; the body is by this action both permanently and sensibly lengthened, or drawn out; and as this extension does not, as in wire-drawing proper, take place under circumstances favorable to increase of toughness, the strength is with the first yielding impaired; while, if the load be not then diminished, the yielding portion must be drawn rapidly smaller until it parts completely. Thus, for ductile materials, the load beyond which permanent change must occur is the limit of strength. In metallic bars or links, timbers, &c., a considerable proportion of the actual strength is gained by means of the firm hold of the fibres laterally one upon another; as is proved by the fact that, of two ropes of like material and containing in their sections a like number of fibres, in one of which the fibres are twisted and in the other glued together, the strength of the latter is greater by at least one third. In ordinary ropes and cords, the strength is that of so many independent fibres, but made effective by means of the enormous friction between these due to the twist, by which the slipping and parting of the mass are prevented. Cords are weakened by overtwisting; but properly made, their strength

increases, for a given thickness, with the fineness both of the fibres and of the strands into which these are first made. Damp hempen cords are stronger than dry ones, twisted than spun, unbleached than bleached, and tarred than untarred. Fibrous and solidified substances of animal origin, as tendons, silk, and glue, have remarkable strength. In the tables of strength which follow, and in which are given as samples the results obtained in reference to certain materials most in use, or otherwise important, the piece experimented on is (unless otherwise specified) always one the transverse section of which presents an area of 1 square inch; and the limits of strength found, known by the loads required to secure fracture, are expressed in pounds weight *avoirdupois*. Some results in respect to tensile strength are given in the following table:

1.—METALS.			
Materials.	Limits of tensile strength.	Materials.	Limits of tensile strength.
Steel, best tempered	124,000—152,000	Iron, ship plates, average	44,000
Steel, cast, maximum	142,000	“ cast	14,000
“ shear	118,000	“ cast, mean of American	45,970
“ blister	104,000	“ cast, mean of American	31,800
“ puddled	67,200	Copper, wire	61,200
“ plates, length-wise	96,800	“ wrought	34,000
“ plates, breadth-wise	73,700	“ cast, American	94,200
“ razor	180,000	Platinum, wire	56,000
Iron, wire	73,000—108,000	Silver, cast	40,000
“ best Swedish bar	72,000	Gold, cast	20,000
“ bar, mean by Barlow	64,560	Tin, cast block	3,800
“ bar, inferior	30,000	“ Banca	2,152
“ boiler plates, average	51,000	Zinc	2,600
		Bismuth	2,900
		Lead, wire	2,580
		“ cast	1,800
2.—OTHER MATERIALS.			
Glass, plate	9,400	Mortar, of 20 years	59
“ flint	4,200	Roman cement, to blue stone	77
Hemp fibres, glued	9,200	“ oak	14,000—24,000
Hemp fibres, twisted (rope)	6,400	“ locust tree	20,100
Manila rope	8,200	“ elm	13,800
Marble, different species	9,000	“ ash	12,000
Stone, different species	1,000	“ fir	8,380
“	850	“ cedar	4,980
Brick, well burned	700		

The strength of metallic bars is impaired by sudden, frequent, or extreme changes of temperature. The strength of alloys is, in many instances, superior to that of either of the component metals. An alloy of 6 parts Swedish copper with 1 of Malacca tin breaks at 64,000 lbs.; brass, at about 51,000; an alloy of 4 parts tin, 1 of lead, and 1 of zinc, at 13,000. According to Mr. Emerson, the load which may be safely suspended to an inch square is as follows:

Iron	76,400	Red fir, holly, elder,	
Brass	55,900	“ plane	5,000
Hemp rope	19,600	Cherry, hazel	4,700
Ivory	15,700	Alder, aspen, birch,	
Oak, box, yew	7,800	“ willow	4,300
Elm, ash, beech	6,070	Lead	450
Walnut, plum	5,800	Freestone	914

The numbers indicate considerable differences in the results as to ultimate strength, as obtained by different experimenters. Of iron, the tenacity is less at 212° than at 82°; but at 392° greater again than at 82°. A convenient

rule for the strength of hemp or wire rope is to allow for each pound weight of the former, per fathom, a strength of 1 ton; of the latter, of 2 tons. Of wood, any species of which is subject to great inequalities, the strongest portion is said to be that neither nearest the pith nor the bark, but between the two. The wood from below the springing of the branches is stronger than that above, and that grown on the south side of the tree than that on the north side. The strength, per square inch section, of any material being known, this becomes for such material the unit or coefficient of strength; and hence, representing this unit for any substance by f , and calling W the breaking weight, and a the area of section in square inches, a general expression for the limit of tensile strength, according to the law found above, will be $W = f \cdot a$. That is, the strength of a piece of any other section is (approximately, of course) found by multiplying the unit for that material by the number of square inches in the transverse section of the piece. But long tie-beams become weaker by having first to do the work of upholding their own weight; and in a long rope, as used in towing, especially when wet, this becomes a serious element of weakness. A like result holds for a long rod or rope, pendent, and intended to support other weights; obviously such rod or rope, loaded, must tend to break near its upper end. Again, the safe load of any piece must diminish with increase of length, owing to greater probability of weak parts; and in some instances a like result arises from long continued pull, apart from the known deterioration, from decay, rusting, jar, &c., with age.

II. Crushing Strength. This form of strength, or that which bodies can oppose to direct thrust, or pressure, is important in all materials having the form of blocks for foundations or walls, in columns, beams, &c. Mr. Hodgkinson finds this form of strength to be dependent in a marked degree (of course, after the nature of the material is regarded) on the proportion borne by the height of the piece to its other dimensions. For heights less than the diameter or side of the piece, the strength against crushing increases as the height is less—short, however, of such thinness as, in more fragile materials, would of itself favor fracture. When the altitude exceeded the diameter, fracture commenced by the cleaving off at the sides of pieces leaving a cone or pyramid of the column; the actual limit of strength was nearly the same up to a height of 4 or 5 times the diameter; beyond this altitude bending in flexible bodies was more likely to occur, and the strength rapidly diminished. Other things being equal, however, the strength was proportional to the area of section. Calling b the breadth, t the thickness, and h the height, Eytelwein had found for crushing strength the formula, $W = f \cdot \frac{b \cdot t^2}{h^3}$. For a solid cylindrical column, the ends flat, the height 30 or more

times the diameter, Hodgkinson finds $W = f \cdot \frac{d^{2.4}}{h^{1.7}}$; and for a like hollow cylindrical column, $W = f \cdot \frac{d^{2.4} - d_1^{2.4}}{h^{1.7}}$; d being the whole diameter of the column, and d_1 the less diameter in case of the hollow column. Here, as before, f is the unit or coefficient, varying with the kind of material; and this, being sought in tables, is to be multiplied by the ratio of dimensions above expressed. The table gives examples of crushing strength for short columns, of 1 square inch area:

Brass, fine.....	164,000	Marble, or granite,	
Iron, cast.....	146,000	about.....	10,000
" wrought.....	72,000	Oak.....	6,000
		Brick.....	1,000

III. Transverse Strength. Suppose a beam stretched horizontally, supported at one or both of its extremities, and having a load placed upon the suspended portion at one or more points. If the beam were either incompressible or inextensible, it could not bend in consequence of the load, but, when the limit of strength was reached, must crush or snap asunder at once. But all materials are susceptible both of compression and of extension—different ones, however, in very different degrees, both as to each of these changes absolutely, and also as to their relative amounts. In fact, a beam supported at the ends or at other points is between any such points of support loaded, first, by its own weight within such length; if any load be then placed upon this portion, the effect is the same in kind, and simply increased in amount. The obvious effect is a deflection or flexure of the beam, under pressure of the sum of the weights its strength must bear. In this deflection the particles and fibres of the under side of the beam are extended, and the actual length of this portion is increased. The fibres are here in a state of tension, cohesion supplying the chief resistance to rupture. The fibres of the upper side of the beam are subjected, on the contrary, to compression; this part of the beam is really shortened; the resistance is that to crushing, and due to action both of repulsion and cohesion. The result is, that in either portion of the bent beam the fibres act by a sort of leverage, one component of their whole pull or pressure being exerted in a direction and amount exactly opposed to the whole transverse strain, at least so long as the piece is not bending, or until it breaks. Between the extended and the compressed portions of the beam there is evidently a continuous film or surface, horizontal when the beam is straight, and correspondingly bent when the beam is so, along which film the material suffers neither extension nor compression. This film, commonly spoken of as a line, is called the neutral line or neutral axis of the beam. Its importance in connection with the strength will presently appear. Since the fibres act by a sort of leverage, in either portion of the beam, most forcibly at the surface, and less and less, down to 0, at the axis, their total action in

either portion must be determined by the number of them in it, and their average distance from the axis. In stones and cast metals generally, the resistance to compression is greater; in woods and wrought metals generally, the resistance to extension is greater. The place of the neutral line, in a general way at about $\frac{1}{2}$ the depth of rectangular beams, is variable slightly in unlike beams of the same form and dimensions. But in any case, in rectangular beams, the mean leverage either of the compressed or extended portion is at $\frac{1}{2}$ its depth. Hence, the entire transverse strength, the foregoing conditions alone considered, will be proportional to the product of the total number of fibres into the depth of the piece; that is, proportional to the product, *area of cross section* \times *depth*; and therefore, as the product, *width* \times *depth*². The dimensions in any two cases compared must correspond in denomination; it is convenient to express widths and depths in inches, and lengths in feet. Now, the strength of beams supported at both ends and loaded at the middle point between supports is generally (calling the breadth b , depth d , and length l) in the ratio $\frac{b \times d^2}{l}$; that is, it is directly as the product above named, and inversely as the length between supports. To find, then, the total strength of a rectangular beam of given material and section, it is necessary to seek its unit or coefficient of strength (that of the square inch section) by experiment or in tables; and having introduced this, the rule becomes, $W = f \cdot \frac{b \cdot d^2}{l}$. As examples, the

unit, f , is, for good cast iron (short lengths, supported at both ends), about 2,548 lbs.; malleable iron, 2,050; Canadian oak, 588. Calling $\frac{1}{2}$ of this ultimate strength the limit of a safe load, the formula becomes, $W = f \cdot \frac{2b \cdot d^2}{2l}$.

When the load is distributed equally along the beam, the strength is practically doubled. The beam being supported at one end only, and loaded at the other, the strength falls to $\frac{1}{2}$ of that obtained by supporting at both ends; but this is in like manner doubled by uniform distribution of load. For some materials, however, the formula gives a theoretical strength too great; for cast iron, by about $\frac{1}{4}$ of the total result. Remembering, now, that the total leverage of the fibres will be as the product of their number into their average distance from the neutral line, it will follow that, for the same quantity and kind of material, the strength can be increased, but within certain limits, by any change in the form of section that carries the fibres further from the neutral axis. When the area of the section is of oblong form, the strength when the beam rests on a narrower side is to the strength when supported on a flat side in the greater ratio of the depth to the thickness. Hence, plain rectangular beams are now seldom made square, but usually as flat prisms, and placed on the narrower side. But with a cross section containing a given total

area of material, still greater gain of strength is secured by carrying a good part of the material out into two lateral extensions, called flanges, united by a vertical portion, the web, thus **I**. Here a positive gain arises through increased leverage; a negative, through saving of weight. For the ultimate transverse strength of rolled or wrought iron flanged beams, calling the depth d , area of section of lower flange A , and that of the web a , the following formula has been obtained: $W = f \cdot \frac{4d}{l} (A + \frac{a}{2})$.

For further particulars in respect to flanged beams, and the differences required in flanges for wrought and for cast iron, see **BRAM**. It has been calculated that with web and flanges of proper form the actual strength of wrought iron beams may be doubled, and of cast iron increased in the ratio $\frac{1}{2}$. In rectangular beams or bars of like material and similar sections, the strength will compare as the cubes of like sides; in cylinders, roughly, as the cubes of the diameters. A difference must be made in estimating the strength of any beam between cases of simple support from beneath, and those in which the end or ends are firmly fixed, as in a wall. The strength in the latter cases will be to that in the former in the ratio of about 3 to 2. The strength of a cylindrical beam is to that of a square beam of like diameter, as 4.71 : 8; that of a prism whose section is an equilateral triangle with the edge up, to that of one of square section and the same area, as 22 : 27; of the prism, equilateral, with the edge down, to a like beam with the edge up, as 38 : 28. In certain experiments upon beams having sections of different forms, the area being in all uniform, and equal to 1 square inch, fixed at one end, and the loads applied to the other at a length or distance of 1 foot, the following results were obtained: a cast iron beam, section square, broke with 678 lbs.; square, a diagonal of the section being vertical, with 568; cylindrical, 578; hollow cylinder, the greater diameter twice the less, 794; rectangular, depth 2 inches, breadth $\frac{1}{2}$ inch, 1,456; rectangular, $8 \times \frac{1}{2}$ inch, 2,892; do., $4 \times \frac{1}{2}$ inch, 2,652; equilateral triangle, edge up, 560; do. do., edge down, 958; T form, 2 inches deep \times 2 wide \times .268 thick, 2,068; same inverted, 555; oak, equilateral triangle, edge up, 114; do. do., edge down, 180. The strength of the largest square timber that can be cut from a tree is to that of the tree itself, as about 10 : 17. But since a beam must bend before breaking, and since a permanent bend is found considerably to reduce the strength for an added load, deflection becomes of itself an element of weakness. Let B denote the amount of deflection, and e the coefficient of elasticity (see **MECHANICS**) of the given material; then, for given dimensions of the piece and amount of load, the deflection will be expressed by the following formula: $B = \frac{W \cdot l^3}{5 \cdot d^4 \cdot e}$; and a given deflection being found experimentally to reduce the load borne by a certain amount, a corresponding deduction

must be made for flexures greater or less. Sometimes the weight of a long beam so nearly breaks it, that a cut across its under surface (acting somewhat on the principle of the incipient fracture started by the diamond in glass) suffices to occasion complete rupture. Peschel advised to saw down into the upper part of a long beam near the middle, and drive in wedges; and in this way, flexure being more powerfully resisted, the strength is greatly increased. The practice of deepening the middle part of a beam, long between supports, appears to be actually injurious; since the maximum strength, with the load distributed, that can be secured with a given weight of material and length of piece, is obtained when the section is slightly less at the middle, and increasing toward the supports. The general principle is that the strength of a beam is increased by whatever contributes to its stiffness. This result is in carpentry secured by increasing or distributing the number of points of support; and also by a special contrivance of several connected pieces of less size, and so adjusted as to secure a continued thrust against or lift upon the middle of the piece to be stiffened. This arrangement, applied either below or above the piece, is called a truss, and the application of it trussing. Since the neutral axis of a beam or of a column contributes nothing to its stiffness or resistance in any way to transverse strain, it may be removed without diminishing the strength. Moreover, the force requisite to sever or bend any bundle of fibres increasing with distance of this from the axis, it follows theoretically that great increase of strength will be secured, with a given weight of material, by giving to this the hollow cylindrical or tubular form. This form more than any other, indeed, augments the strength toward bending or crushing strains. Tredgold finds that in such a cylinder, the inner diameter being to the outer as 7 : 10, the strength is doubled; and that it is greatest when the diameters are as 5 : 11. A rectangular beam, area 1 square inch, length 1 foot, sustained about $2\frac{1}{2}$ tons; a hollow cylinder of like area of metal sustained $13\frac{1}{2}$ tons; and a rectangular hollow beam, $8\frac{1}{2}$ tons. Obvious instances of gain of strength and lightness at the same time by conformity to this principle, are seen in the long bones of the vertebrate animals, especially in those of birds, in the quill part of feathers, and in hollow stems, as the straw of wheat. Applications of the principle in the arts of construction have latterly attained to great importance; among them are the use of hollow iron columns in building; the tubular bridges; the cellular structure, as in the double sides of iron ships, the space intervening being cut up by transverse plates, made both to bind and brace between the two; and fluting or corrugation of metallic sheets or walls, which thus, though light, may have the stiffness and strength of much thicker ones. IV. The torsional strength, being rarely of importance in practice, may be omitted.—It

has often been observed that wheels, chains, beams, cranes, and other iron structures, after being long subjected to blows or to distinct jarring during use or in any manner, at length break, and apparently without adequate cause. On the London and Blackwall railway, cars were run by a stationary engine, by means of a wire cable $6\frac{1}{2}$ miles long. This, however well made, broke, it was found, after a time, though showing no visible wear or other deterioration. It is known that by continued rolling, hammering, or wire-drawing, metals lose their toughness and become fragile. It is asserted, and, though the question is yet somewhat in dispute, is probably true, that the tough metal is fibrous or laminated in structure, while the fragile or deteriorated pieces have become granular or crystalline. It is probable, therefore, that under continued agitation the molecules of the body undergo a new arrangement, in consequence of which its properties are changed, its tenacity and strength diminished. It has been proposed to call this condition fatigue of the metals. Applications of the principle are seen in the liability of cannon after being fired many times to burst, so that usually, after a certain number of discharges, pieces are now condemned and laid aside; and also in the danger from long use of breakage in car wheels, the chains used in hoisting from mines, in axles, &c. In two like structures of very different sizes, the larger is relatively weaker in consequence of its increased weight. At a certain size a structure would reach its 0 of strength for outside load, and beyond this would fall by its own weight. This result must follow because, while the strength of a structure is in a general way augmented in the ratio of the square of any certain dimension, the weight will increase usually as the cube of the given dimension. Of two like structures, one having its corresponding dimensions 4 times that of the other, the first will hence have a theoretical strength about 16 times that of the second, but a weight about 64 times that of the second. Hence, all unnecessary weight in the parts of a structure is a source of positive weakness; and in all our constructions a practical limit of size must be reached sooner or later. Hence, also, it is that we cannot judge of the effective strength of a structure from the actual ratio of strength afforded by its model. And a like principle furnishes one among the reasons why the smaller animals have relatively to their size a greater available strength than larger ones.—For further study of this subject the reader is referred to the works of Barlow, Fairbairn, Hodgkinson, Tredgold, and Emerson (English); to Tate on "Strength of Materials" (London, 1851); to the "Report of the Royal Commissioners on Iron" (London, 1849); and to a series of articles on "Strength of Materials, deduced from the latest Experiments of Barlow, Hodgkinson, &c.," in the "Journal of the Franklin Institute," Philadelphia, commencing in Nov. 1860.

STRICKLAND. I. **AGNES**, an English authoress, born at Reydon hall, Suffolk, in the early part of the present century. She was carefully educated under the personal supervision of her father, and at the age of 16 produced a poem in 4 cantos entitled "Worcester Field, or the Cavalier," which Campbell pronounced the best work of its class since the appearance of Scott's metrical romances. It was followed during the next few years by "Demetrius," a novel, of which the scene is laid in modern Greece; "The Pilgrims of Walsingham," a series of tales constructed on the plan of Chaucer's "Canterbury Pilgrims;" "Alda, the British Captive;" and several popular historical and biographical works for children. In 1840, in conjunction with her sister Elizabeth, she commenced the elaborate series of the "Lives of the Queens of England," completed in 1849 in 12 vols., which was followed by "Lives of the Queens of Scotland" (8 vols., 1850-'59). Both have proved very popular, and the biography of Mary, queen of Scots, in the latter series, by Agnes Strickland, is an elaborate attempt, founded on a variety of documents not previously consulted in detail, to establish the innocence of that sovereign. In 1861 she published "Lives of the Bachelor Kings of England," completing, with her "Queens," a continuous series of English history. At various times Miss Strickland has been a contributor of prose and verse to the periodicals, and a collection of her articles has been reprinted under the title of "Historical Scenes." II. **JANE MARGARET**, sister of the preceding, commenced her literary career as a contributor to juvenile annuals and religious publications, to which occupation she devoted herself for several years. In 1854 she published "Rome, Regal and Republican" (2 vols. 8vo.). III. **CATHARINE PAER** (Mrs. TRAIL), sister of the preceding, has resided for several years in Canada, where her husband, Lieut. Trail, of the 21st regiment, was quartered, and has produced "The Backwoods of America," "The Canadian Crusoes," and "A Guide to Female Emigrants." IV. **SUSANNAH** (Mrs. MOODIE), another sister, married an officer in the same regiment with Lieut. Trail, and is also a resident in Canada. Her works comprise "Mark Hurdlestone" and "Flora Lindsay," novels, and "Roughing it in the Bush," a history of her personal adventures in the new world.

STRICKLAND, WILLIAM P., D.D., an American clergyman and author, born in Pittsburg, Penn., Aug. 17, 1809. He was educated at the Ohio university, Athens, O., entered the itinerant ministry of the Methodist Episcopal church in Ohio in 1832, and was afterward for some years agent and district secretary of the American Bible society. In 1856 he removed to New York, where he has been engaged in literary labor, mostly in connection with the Methodist book concern. He is now (Jan. 1863) chaplain of the 48th New York regiment, stationed at Port Royal, S. C. His principal

publications are: "History of the American Bible Society" (New York, 1849; new ed., 1856); "History of Methodist Missions" (1850); "Genius and Mission of Methodism" (1851); "Christianity Demonstrated" (1852); "Memoir of the Rev. James B. Finley" (1853); "A Treatise on Biblical Literature" (1853); "The Light of the Temple," a masonic work (Cincinnati, 1854); "The Astrologer of Chaldea" (Cincinnati, 1856); "Pioneers of the West" (New York, 1856); "Life of the Rev. Francis Asbury (Pioneer Bishop)" (1858); "Life of Jacob Gruber" (1859); and "Old Mackinaw" (Philadelphia, 1860).

STRONG, CALER, an American statesman, born at Northampton, Mass., Jan. 9, 1745, died there, Nov. 7, 1819. He was graduated at Harvard college in 1764, studied law, and was admitted to the bar in 1772. During the revolution he was a member of the general court or legislature and of the Northampton committee of safety. For nearly 25 years after 1776 he was county attorney, in 1779 was a member of the state constitutional convention, and in 1780 of the state council, and several times represented his county in the state senate. In 1787 he was elected to the convention for framing a national constitution, but was obliged by sickness in his family to return home before the completion of its labors; and in 1789 he was elected one of the first U. S. senators from Massachusetts, was reelected in 1793, and resigned in 1796. From 1800 to 1807 he was governor of Massachusetts, and again from 1812 to 1816. As a federalist he was opposed to the war with England, and his conduct during the war was the subject of severe animadversion by his political opponents. When requisition was made upon him for troops, he, in common with the whole federal party of New England, denied the right of the president upon constitutional grounds, and stood aloof from the contest, until what seemed to be a retaliatory act of the administration in withdrawing nearly all the troops from the coast of Massachusetts, and the actual presence of the enemy, rendered it imperative that he should make every effort for the defence of the state. The constitution specified three cases in which the president could call upon a state for the militia, viz.: to execute the laws, to suppress insurrection, and to repel invasion. A difference of opinion arose between the president and the governor as to which was to decide that either of these exigencies existed. There had then been no judicial decision on the subject, and the opinion of the supreme court was asked on the questions whether the commanders-in-chief of the states had a right to judge of the exigency, and whether, when either of the three exigencies did exist, the militia could be lawfully commanded by any officer but of the militia. An answer to these questions was returned, signed by Theophilus Parsons, Samuel Sewall, and Isaac Parker, sustaining the governor in his interpretation of the constitution. But although Gov. Strong

so emphatically declined answering calls which he considered unconstitutional, he was ready to adopt every measure which the safety of the state demanded, and to accede to all requests which he considered within the limits of his constitutional obligations; and the state throughout the war was amply defended, so that no evil resulted from the difference between the state and national authorities.

STRONG, JAMES, an American theological writer, born in New York, Aug. 14, 1822. He was graduated at the Wesleyan university, Middletown, Conn., in 1844. In 1852 he published a "Harmony and Exposition of the Gospels," and in 1854 a "Greek Harmony of the Gospels" on a similar plan, and also an abridgment of the forms and questions upon it. He is also the author of brief manuals of Greek and Hebrew grammar, an outline of theology, and an "Appeal to Sunday School Efforts;" and of various articles, chiefly on biblical topics, in the "Methodist Quarterly Review," and a series of communications in the "Christian Advocate and Journal," on the subject of ministerial education, which elicited much controversy. He has been for several years engaged, in connection with the Rev. Dr. McClinton, on an extensive "Cyclopædia of Biblical, Theological, and Ecclesiastical Literature," which is now (Feb. 1862) nearly ready for publication. In 1856 he received, although a layman, the honorary degree of D.D. from the Wesleyan university. In 1858 he became professor of biblical literature and acting president of the Troy university, N. Y., which position he resigned in Dec. 1861.

STRONTIA, or STRONTIAN, an alkaline earth, of which strontium is the metallic base, represented by the formula SrO , chemical equivalent 52, obtained from its nitrate by ignition. It was first distinguished from barytes by Dr. Hope in 1792, and was named by him from Strontian, in Argyleshire, Scotland, where the mineral compound containing it was found. Pure strontia is prepared in the same manner as barytes from its corresponding salts. It is a grayish white, porous substance, infusible, not volatile, of alkaline reaction, and having an acrid, burning taste. It slakes like lime, and dissolves in 2 parts of boiling water or 50 parts of cold water. It resembles barytes, but its salts are not poisonous like those of the latter substance. Combined with carbonic acid, it forms the mineral strontianite, which occurs in Scotland in veins traversing gneiss along with galena and heavy spar. It consists of strontia 70.19 and carbonic acid 29.81 per cent. It is of light shades of yellow or green, gray, or white, more or less transparent; lustre vitreous; hardness 3.5 to 4; specific gravity 3.605 to 3.713. Its chief interest is in its property of communicating a reddish tinge to flame. In the United States the mineral occurs at Schoharie and at Warwick, Orange co., and at several localities in Jefferson co., N. Y. Strontia also occurs combined with sulphuric acid, forming

the mineral celestine or sulphate of strontia, which consists of strontia 56.4 and sulphuric acid 43.6 per cent. This is of vitreous lustre, white or faintly bluish or reddish, and more or less transparent; hardness 3 to 3½; specific gravity 3.95. Its crystals are modified forms of the right rhombic prism, and are found in great perfection and of large size on Drummond's island, Lake Huron.—The nitrate is the only strontia compound of importance. It is the ingredient used in fireworks for giving a crimson color to the flames, and is prepared by converting the native sulphate into the sulphuret by heating it mixed with charcoal in a crucible, and decomposing the sulphuret, dissolved in water, with dilute nitric acid. Colorless transparent crystals of slender octahedral form separate on the evaporation of the neutral or acid solution. The salt is insoluble in alcohol, but dissolves in 5 parts of cold and one half part of boiling water. A beautiful exhibition of red fire is prepared by treating bibulous paper with nitric and sulphuric acids, and, after washing out all the free acid and drying, saturating it with a solution of the nitrate of strontia or chloride of strontium. The chloride is prepared by using hydrochloric instead of nitric acid in decomposing the sulphuret. A mixture that deflagrates with a magnificent red color, but which is very dangerous to make and to keep, is prepared of 40 parts of nitrate of strontia, 5 of chlorate of potash, 18 of sulphur, and 4 of sulphuret of antimony. Its spontaneous explosion has been the cause of some frightful accidents.—Strontium, the metallic base, was first isolated by Davy in 1807, but was first obtained in a pure state by Bunsen and Matthiessen in 1855. It is a malleable metal, of pale yellow color, and burns in the air with a yellowish flame emitting sparks.

STROPHE (Gr., from *στροφή*, to turn round), a division of the Greek choral ode, much the same as a stanza. Opposed to it is the antistrophe. The chorus recited these various parts of the poem with their faces toward the different sides of the theatre, and turned to the one or the other side as they began the respective divisions; hence the name.

STRUENSEE, KARL AUGUST VON, a German statesman and author, born in Halle, Aug. 18, 1735, died in Berlin, Oct. 17, 1804. He was educated at the orphan house and the university of Halle, and in 1756 was appointed a lecturer on mathematics and Hebrew at Halle, and the next year professor at the military academy of Liegnitz. In 1769 he was called by his brother Count Struensee to Copenhagen to take charge of the finances of the Danish kingdom, and on his brother's downfall was imprisoned for a short time, but was soon released, returned to Prussia, and retired to his country seat at Alzenau in Silesia. In 1782 he was made councillor of finances and director of maritime trade at Berlin, and distinguished himself by measures which greatly increased the trade of Prussia. In 1789 he was ennobled

under the name of Von Karlsbach, and in 1791 appointed minister of state, and president of the board of excise, which office he held till his death. He published several valuable works on military science, political economy, and commerce.—JOHANN FRIEDRICH, count, a Danish statesman, brother of the preceding, born in Halle, Aug. 5, 1737, executed at Copenhagen, April 28, 1772. His early education was acquired in Francke's orphan house, and he studied medicine at the university of Halle, receiving his diploma in 1757. He was soon after appointed public physician at Altona, and in 1768 was employed to attend Christian VII. of Denmark in his tour through Germany, France, and England. His agreeable and insinuating manners won the confidence of the king, and he was a ready companion in his profligacy. With consummate address, he gained the good will of the queen (Caroline Matilda, sister of George III. of England), who was at first prejudiced against him, and for nearly 8 years he was the actual ruler of Denmark. In 1770 he was intrusted with the physical education of the crown prince, afterward Frederic VI., and soon after caused the king to deprive Count Bernstorff of his seat in the council of state, and appoint Count Rantzau-Aschbach in his place. He obtained the recall from France of his profligate friend Enevold von Brandt, who had been banished some years before, and through him he accomplished many of his purposes. The king gave himself up to vicious indulgence, and two parties strove to obtain the power, the party of the queen dowager led by Count Bernstorff, and the party of the queen led by Struensee. The latter triumphed, and Struensee was appointed prime minister with almost unlimited powers. He soon persuaded the king to dissolve the council of state, and to institute in its place the commission of conference, composed of his own creatures. This measure, though confirming his power at the time, brought great odium on Struensee, as subverting, through the influence of a foreigner, the Danish constitution, and depriving the nobility of their hereditary power. Count Rantzau, who had been promoted by his influence, being deprived by this act of office, went over to the party of the queen dowager, and became one of his bitterest enemies. The finances of the country were in a bad condition, and by injudicious measures of taxation he increased the public hostility to his administration. Scandals were circulated in regard to his relations with the queen, and he suppressed them by silencing the press. The party of the queen dowager, bitterly hostile to him, sought an opportunity of destroying him, and the partial failure of his intellectual powers, overtaken by his labors and his licentiousness, soon furnished it. The king was forced by the queen dowager and her partisans to sign an order for the arrest of Struensee and his brother, whom he had made councillor of justice, Brandt, Queen Caroline

Matilda, and all their adherents, which was accomplished Jan. 16, 1772. Struensee and Brandt were tried by a special commission, and sentenced to decapitation, their right hands to be cut off, their bodies quartered and broken on the wheel, and their heads and hands to be stuck upon a pole. This sentence was carried into effect in all its details. During his imprisonment Struensee professed penitence and conversion from scepticism to Christianity, and made a written confession of his errors and crimes.

STRUTT, JOSEPH, an English antiquary and artist, born in Springfield, Essex, Oct. 27, 1742, died in London, Oct. 18, 1802. At 14 years of age he was apprenticed to Ryland, the engraver, and he subsequently studied oil painting at the royal academy, although he never accomplished much in that line. A taste for antiquities led him to pass much time in the reading room of the British museum, and an examination of the rare manuscripts resulted in the preparation of his first work, "The Regal and Ecclesiastical Antiquities of England, containing the Representations of the English Monarchs from Edward the Confessor to Henry VIII." (4to., 1773). His remaining works comprise "Horda-Angel-Cynnan, or a Complete View of the Manners, Customs, Arms, Habits, &c., of the Inhabitants of England from the arrival of the Saxons" (3 vols. 4to., 1774-'6); "Chronicle of England" (2 vols. 4to., 1777-'8), intended to comprise 6 vols., but which from want of encouragement he terminated with the Norman conquest; "Biographical Dictionary of Engravers" (2 vols. 4to., 1785-'6); "Complete View of the Dress and Habits of the People of England, from the Establishment of the Saxons" (2 vols., 1796-'9); and "The Sports and Pastimes of the People of England" (4to., 1801), a popular work, and well known by Hone's edition (8vo., 1830). He left, beside some miscellaneous pieces, a fragment of a romance entitled "Queen Hoo Hall," which, at the request of Murray the publisher, was completed by Sir Walter Scott in 1808. Strutt also engraved a series of plates illustrating the "Pilgrim's Progress," and a number of single works. He died in poverty.

STRUVE, FRIEDRICH GEORG WILHELM VON, a Russian astronomer, born in Altona, April 15, 1793. He was educated at the university of Dorpat, and in 1813 was attached to the observatory of that city, of which he became director in 1817. In 1839 he was made director of the magnificent observatory of Pulkowa, which position he still retains, and was not long after made councillor of state. He has confined his labors as an astronomer principally to the observation of fixed and double stars, and has made large additions to the knowledge of these bodies. He has also been engaged in a variety of labors connected more or less intimately with astronomical science, such as the triangulation of Livonia, measuring the degrees of latitude in the Baltic provinces, meas-

uring an arc of the meridian between Sweden and southern Russia, the observation of the eclipses of 1842 and 1851, &c. His most important works are: *Observationes Dorpatenses* (8 vols., Dorpat, 1817-'89); *Catalogus Novus Stellarum Duplicitium* (Dorpat, 1827); *Stellarum Duplicitium Mensura Micrometrica* (St. Petersburg, 1827); *Études d'astronomie stellaire sur la voie lactée et la distance des étoiles fixes* (St. Petersburg, 1847); and *Stellarum Fixarum imprimis Duplicitium et Multiplicitium Positiones Medie pro Epocha 1880*, &c. (fol., St. Petersburg, 1852). He has contributed much to the "Transactions" of the academy of sciences of St. Petersburg.—OTTO WILHELM, son of the preceding, born May 7, 1819. Educated under his father's direction, and now second astronomer at Pulkowa, he has distinguished himself by numerous astronomical discoveries, including over 500 new double stars and a satellite of Uranus, and by some interesting conclusions in regard to the ring of Saturn. He has published narratives of two chronometric expeditions undertaken by order of the Russian government, and observations on Biela's comet.

STRUVE, GEORG ADAM, a German jurist, born in Magdeburg, Sept. 26, 1619, died in Jena, Dec. 13, 1692. He studied law at the universities of Jena and Helmstedt, and in 1646 was appointed professor of law in the former, and in 1648 assessor to the high court of the circle of Saxony. In 1667 he was appointed privy councillor to the duke of Weimar, and was selected as his advocate in the case of the succession to the duchy of Saxe-Altenburg. In 1674 he returned to Jena as professor of canon law and *ordinarius* of the judicial college, and in 1680 was appointed president of the regency at Jena, the duke being a minor. He published 18 elaborate treatises on law, of which the most important are: *Syntagma Juris Feudalis* (Jena, 1658); *Syntagma Jurisprudentie Civilis* (1665); and *Jurisprudentia Romano-Germanica Forensis* (1670).—BURKHARD GOTTHELF, a German jurist, son of the preceding, born in Weimar, May 26, 1671, died in Jena, May 24, 1788. He studied at Jena and various other German and Dutch universities, and in 1692 engaged at Jena with one of his brothers in the pursuit of the philosopher's stone, in which they soon beggared themselves. He afterward devoted himself for two years to the study of the Scriptures and the writings of Tauler and Arndt, and in 1697 was appointed curator of the library of the university of Jena. In 1704 he succeeded Schubart as professor of history, and in 1712 was appointed by the university historiographer and councillor, and extraordinary professor of law. In 1717 he was appointed privy councillor by the reigning prince of Baireuth, and in 1780 by the Saxon court. He was one of the first to attempt to reduce statistics to a system. The most important of his numerous works is his *Corpus Juris Gentium* (Jena, 1748).

STRUVE, GUSTAV VON, a German writer and politician, born in Livonia in 1805. He studied law at the German universities, was for some time secretary of the embassy of Oldenburg at Frankfort, and soon after settled as a lawyer at Mannheim in the grand duchy of Baden, where he made himself known as a liberal journalist, as a speaker in political meetings, and as a phrenologist. In 1848 he made two fruitless insurrectionary attempts to introduce a republican form of government into Baden, and after the first failure retired to Switzerland, where he published with K. Heinzen a "Plan for Revolutionizing and Republicanizing Germany." The second attempt ended with a defeat at Staufen. Being arrested on Sept. 25, he was sentenced on March 30, 1849, to imprisonment for life. He was however on May 24 liberated by the success of the revolution, and elected a member of the constituent assembly of Baden, in which he was the principal leader of the republican party. After the dissolution of the constituent assembly and the suppression of the revolution he went to Switzerland, which he was soon forced to leave. He then went to England, and in 1861 came to the United States, where he first commenced the publication of a political weekly journal (*Der Zuschauer*), and after its discontinuance devoted himself to the compilation of a universal history of the world. After the outbreak of the civil war in the United States in 1861 he entered the ranks as a private soldier, but was soon elected captain in the 8th regiment New York volunteers. Beside several works on phrenology, he has published *Das öffentliche Recht des Deutschen Bundes* (2 vols., Mannheim, 1846); *System der Staatswissenschaften* (4 vols., Frankfort, 1847-'8); *Geschichte der drei Völkerhebungen in Baden* (Bonn, 1849); *Weltgeschichte* (9 vols., New York, 1854-'8); and *Das Revolutions Zeitalter* (New York, 1859-'60).

STRYCHNIA, or STRYCHNINE, a poisonous alkaloid obtained from several species of plants of the genus *strychnos*. (See *Nux Vomica*.) It was discovered in 1818 by Pelletier and Carenton in the *nux vomica* and bean of St. Ignatius, to the amount of 0.4 per cent. in the former, and 1.2 per cent. in the latter. The *S. ticutis* affords it most readily and of the purest quality, but this species is too rare to be of practical importance; and the bean of St. Ignatius for a similar reason is little employed compared with the *nux vomica*. Several methods are adopted for reducing the seeds to powder before extracting the alkaloid. They are rasped with a file, or softened by steam, then sliced and ground when dry; or, as practised by the large manufacturers, the whole seeds are macerated in dilute sulphuric acid, and steam is passed through them in a covered vat lined with lead. They are then ground, and the pulp is lixiviated or expressed. If pure water alone is used, the strychnia is obtained as an igasurate, and if it is acidulated with sulphuric or hydrochloric acid, then as a salt

of these acids. After the infusion is concentrated, the salt is decomposed by adding lime, and the strychnia falls with the excess of lime and impurities. These being separated, boiling alcohol dissolves the strychnia, and by evaporation this is obtained in crystals, which may be purified and decolorized by redissolving and crystallizing several times, or by converting into a sulphate with sulphuric acid, then decolorizing with animal charcoal, and recovering the strychnia by decomposing the salt with ammonia. The alkali brucia accompanies the strychnia, and may be almost entirely removed in the repeated treatment with alcohol, in which when cold brucia is much more soluble than strychnia. Their medicinal properties are very similar, but much less strongly marked in brucia. When strychnia is rapidly crystallized from its solution, it is a white granular powder; but if time be given it crystallizes in octahedrons or quadrilateral prisms. Microscopic crystals were observed by Dr. J. J. Reese of Philadelphia on evaporating single drops of water upon a slip of glass, when the quantity present could not exceed $\frac{1}{100,000}$ of a grain in weight. Some of the crystals appeared circular, others stellate and scalloped, intermingled with dentated crosslets. His paper upon strychnia in the "American Journal of the Medical Sciences," for Oct. 1861, presents much valuable information upon this substance and the means of detecting its presence, and is the authority for what follows respecting the methods of detecting it. Strychnia is an intensely bitter substance, one grain, according to Dr. Reese, dissolved in 25 gallons of water, communicating a perceptible taste when the mouth is forcibly rinsed with the water. It is without odor, and undergoes no change in the air. Exposed to heat, it is not volatile, but melts like a resin, and is soon decomposed. It dissolves in the volatile oils and in boiling alcohol, but scarcely at all in water, ether, or absolute alcohol. Its composition, according to Liebig, is represented by the formula $N_2O_4H_{12}$, but other authorities give very different proportions of these elements. The salts of strychnia when in solution are decomposed by the alkalies and their carbonates and by tannic acid.—The effects of strychnia upon the animal system are very remarkable. It is one of the most active and deadly poisons known. One sixth of a grain of the pure alkali has been known to kill a dog in half a minute, and less than a grain would probably destroy human life. The strength of the commercial article is, however, very variable. The poison acts alike whether applied externally to a fresh wound or injected into the veins, and its effects are communicated by injecting the blood of an animal under its influence into the veins of another; they are exhibited by convulsions soon terminating in death. Various antidotes have been proposed, but in cases of poisoning there can rarely be time for their exhibition. Camphor taken internally is said to correct the

poisonous effects, and chloroform is probably still more efficacious. Conium is the most exact antidotal or antagonistic remedy. A case is reported of a boy in Cortland co., N. Y., who took about two grains of strychnia in mistake for morphia, and was soon after seized with violent tetanic spasms, locked jaw, &c. Chloroform was administered freely, by inhalation and application along the spine, and in 10 minutes the patient became perfectly quiet under its influence. On withdrawing it the spasms returned; but by keeping him under the effects of the anæsthetic $4\frac{1}{2}$ hours, the poison was absorbed and the boy recovered. As a medicine strychnia is employed for the same purposes as nux vomica, and is introduced into the system either by application to a fresh wound, injection into the veins, or by taking it internally in pills or in solution in acidulated water. The pills commonly contain from $\frac{1}{12}$ to $\frac{1}{4}$ of a grain each, and after the first dose the others are regulated according to the observed effects, the strength of the medicine being always uncertain. Strychnia is the most useful remedy against muscular debility and simple paralysis, and for constipation arising from debility of the muscular coat of the bowels.—The presence of strychnia, even in inconceivably small quantities, is indicated by several curious and most satisfactory tests. The chief of these, called the color test, depends on the property, peculiar to strychnia, of exhibiting a beautiful play of colors when, in the presence of sulphuric acid, it is brought in contact with certain oxidizing bodies, such as the peroxides of lead and manganese, bichromate of potash, ferridcyanide of potassium (red prussiate), and permanganate of potash. When a small fragment of strychnia on a white plate is moistened with a drop of strong sulphuric acid, and either one of these bodies is stirred in contact with it, a rich violet blue color appears, which very soon changes to a mulberry purple, and afterward to light red. Dr. Reese is positive that the reactions of some other substances cited as resembling those of strychnia under these circumstances are in reality different when the experiment is carefully made. So delicate is this test, that he succeeded in detecting by it the presence of strychnia in pure solutions containing only $\frac{1}{100,000}$ of the alkaloid. In mixtures, such as the contents of the stomach, containing organic substances, it is readily discovered when present in proportion equal to $\frac{1}{10}$ of a grain to a pint of the mixture, this being first reduced to a small bulk by evaporation. A drop of the matter to be tested is very carefully evaporated to dryness at a temperature too low for the strychnia to be decomposed, upon a clean white porcelain surface. A drop of pure and strong sulphuric acid, taken out of the bottle on the end of a finely pointed glass rod, is then placed near to the dry spot on the porcelain, and a little of it is to be drawn along in contact with the spot. Then a very small crystal of the bichromate of

potash, or, better, of the ferridcyanide of potassium, is to be moved once or twice over the moistened spot, when the characteristic reactions will be observed in case of the presence of strychnia. Instead of using an oxidizing body, Dr. Letheby brings out the blue color from the spot evaporated to dryness on a piece of platinum foil, and moistened with sulphuric acid, by connecting the foil with the positive pole of a single cell of Grove's or Smee's battery, and the acid with the negative pole. This method is not found so satisfactory by Dr. Reese, for several reasons, as that already given. Both of them fail when morphia in equal or larger quantities than the strychnia has been added to the mixture of organic substances. Another method of detecting the presence of strychnia is by what is known as the frog test. If the body and hind legs of a frog are immersed in a strychnia solution, tetanic spasms ensue on the absorption of an exceedingly small portion of the poison; the same effect follows the injection of a few drops through the oesophagus, or into the tissue of the thorax or abdomen. The smallest sized frogs should be selected, not more than $1\frac{1}{2}$ inches long or of 50 grains weight. A frog weighing 29 grains treated for half an hour by the first method, in a solution containing one grain of strychnia to 3 gallons of water (each drop consequently representing $\frac{1}{330,000}$ of a grain), exhibited decided convulsions and suddenly died. This test, in connection with the color test and the extreme bitterness of strychnia solutions, is regarded as abundantly sufficient to determine the presence of the alkaloid. The frog test is particularly valuable because it is scarcely affected, if at all, by the presence of morphia.

STRYPE, JOHN, an English divine and author, born in London, Nov. 12, 1643, died Dec. 18, 1737. He was educated at St. Paul's school and at Cambridge, and in 1669 became minister of Low Leyton in Essex, where he continued until a few years previous to his death. His principal works are: "Memorials of the most renowned Father in God, Thomas Cranmer, sometime Lord Archbishop of Canterbury" (fol., 1694); "The Life of the Learned Sir Thomas Smith" (8vo., 1698); "Historical Collections relating to the Life and Acts of Bishop Aylmer" (8vo., 1701); "Annals of the Reformation" (4 vols. fol., 1709-'81); and "Ecclesiastical Memoirs" (8 vols. fol., 1721). He published an edition of Stow's "Survey of London" (2 vols. fol., 1720), though Stow's matter was but little more than a nucleus for his own accumulations in antiquarian research. His works were reprinted at Oxford (29 vols. 8vo., 1822-'8), affording very valuable documents for the ecclesiastical history of England.

STUART, the name of a royal family of Scotland and England. The origin of the family is involved in some obscurity; but according to tradition, Fleanchus, son of Banquo, on the murder of his father by Macbeth, fled

into Wales in 1055, where he married a daughter of a chief named Griffithar Llewellyn; the son of Fleanchus, Walter I. (died 1118), returned to Scotland, and became steward of the household of Malcolm III., which office was made hereditary in his family, and from which the surname Stuart was derived. Walter was succeeded by his son Alan, he by another Walter, 8d high steward, and he by Alexander, who in 1199 was slain in a battle with the Danes, and left his office to his son Walter III., who conspired against King Alexander II., and was subsequently poisoned by his wife Alda of Dembe. Walter's son and successor Alexander was regent during the minority of Alexander III. His son James was regent after the death of that king, and died in 1309. Walter III., who succeeded his father, married Marjory, daughter of Robert Bruce, in 1315, upon whom, in failure of the birth of an heir male to her father, the crown was settled by act of parliament at Ayr, April 26, 1315. Marjory died in giving birth to Robert, afterward Robert II. of Scotland; but David II., son of Robert Bruce by a second marriage, came to the throne in 1324 as a minor, and after a succession of regencies Robert the Stewart, in conjunction with the earl of Moray, became regent in 1334, having already distinguished himself in the battle of Halidon, when, though but 16 years of age, he commanded a division of the Scottish army. In 1335, the earl of Moray having been taken prisoner by the English, he concluded a treaty with Edward III. of England. In 1338 he was appointed sole regent, which office terminated in 1341 by the king's majority. In 1346, David being taken prisoner, he was again elected regent, and held the position till 1357, when David was released. On the death of David in 1370 he was unanimously declared king with the title of Robert II. The licentiousness of this monarch, the doubts of the legitimacy of the children of his first wife, and the chronic state of war with Great Britain, made his reign and that of his son Robert III. harassing and unfortunate for the people. Robert II. died in 1390, and Robert III. in 1406. The succeeding monarchs of the line (all of whom are treated in separate articles) were James I., assassinated in 1437; James II., who died a violent death in 1460; James III., murdered in 1488; James IV., slain in the battle of Flodden in 1513; James V., son of the preceding and of Margaret Tudor, sister of Henry VIII. of England, died in 1542; Mary, executed in England in 1587; her son James VI., who succeeded Queen Elizabeth as James I. of England, and died in 1625; Charles I., executed in 1649; Charles II., died in 1685; James II., who was expelled from the kingdom in 1688, and died in 1701, and was the last reigning male member of the family, though his daughter Mary, wife of William of Orange, came to the throne as queen regnant with her husband, and his second daughter Anne succeeded her in 1702, reigning till her death in

1714. The only son of James II., James Francis Edward Stuart, was a pretender to the throne of England, and died in Rome in 1766. His son Charles Edward Stuart (born in 1720, died in 1788), was a second pretender to the English throne. Henry Stuart, Cardinal York, brother of Charles Edward, was the last of the male line of the family, and with his death in 1807 it became extinct. Its chief branches in the female line are the houses of Savoy and Orleans and the duke of Modena, all descended from Henrietta Maria, daughter of Charles I., of which king the duke of Modena is the lineal representative, being thus, but for the act of settlement, heir to the crown of England. (See CHARLES EDWARD, JAMES FRANCIS EDWARD, and STUART, H. B. M. C.).

STUART, GILBERT, a Scottish author, born in Edinburgh in 1742, or according to some authorities in 1746, died in Musselburgh, Aug. 12, 1786. He was educated at the university of Edinburgh, where he studied jurisprudence and general literature, and in 1767 published a "Historical Disquisition concerning the Antiquity of the British Constitution," which procured him the degree of LL.D. Encouraged by the success of his next work, a "View of Society in Europe in its Progress from Rudeness to Refinement" (1768), he made application for the vacant professorship of public law in the university of Edinburgh; and failing in this, on account of his character for dissipation, he repaired to London, and for several years was a contributor to the "Monthly Review." Returning to Edinburgh in 1773, he started, in conjunction with William Smellie, the "Edinburgh Magazine and Review," which for 4 years was made the vehicle of savage strictures from his pen on prominent Scottish authors. This embittered spirit is observable in his next work, "Observations concerning the Public Law and Constitutional History of Scotland" (8vo., Edinburgh, 1779), an attack on Dr. Robertson, whom he especially hated. In 1780 he published a "History of the Establishment of the Reformation of Religion in Scotland" (4to., London), and in 1782 a "History of Scotland from the Reformation to the Death of Queen Mary" (2 vols. 8vo., London), in which he again attacked Robertson, whose aspersions against the character of the Scottish queen he zealously repelled. This is considered his ablest performance. For several years subsequent to 1783 he lived in London, contributing articles written in his characteristic vein to the "Political Herald" and the "English Review," of which John Murray was the proprietor; and a few months previous to his death he returned to Scotland.

STUART, GILBERT CHARLES, an American painter, born in Narragansett, R. I., in 1756, died in Boston in July, 1838. He received his first instructions from a Scottish painter named Alexander, by whom, when about 18 years of age, he was taken to Edinburgh. His master dying soon after their arrival in that city, he

returned to America, working his passage home, it is said, before the mast, and commenced practice as a portrait painter at Newport, R. I. He removed thence successively to Boston and New York; but finding the war of the revolution a hopeless obstacle to his prospects, he set sail in 1778 for London, where for a couple of years he led an irregular life, making little progress toward establishing a reputation, and often at a loss for actual necessities. Having finally been introduced to Benjamin West, then at the height of his fame and influence, he received from him valuable assistance in money and instruction, and for several years resided in his family. These attentions were warmly acknowledged by Stuart, who painted a full-length portrait of his benefactor, which is now in the British national gallery. About 1781 he commenced practice in London on his own account, and soon rose to great eminence as a portrait painter, rivaling Reynolds and the best English artists of the day in that department. Among his numerous sitters were George III., the prince of Wales, the earl of St. Vincent, the duke of Northumberland, Sir Joshua Reynolds, John Kemble, Col. Barré, Alderman Boydell, and many other distinguished persons. Subsequently he resided successively in Dublin and Paris, and in the latter city painted a portrait of Louis XVI. Returning to America in 1798, he proceeded, after a short stay in New York, to Philadelphia, for the purpose of painting the portrait of Washington. The first picture he destroyed; but at the second sitting he succeeded in producing the well known head from which he painted all his other portraits of Washington, and which has long been regarded as the standard likeness. The original study, together with a head of Mrs. Washington, is now in the possession of the Boston Athenæum. After residing several years in Washington, he took up his permanent abode in 1806 in Boston, where he continued in the active practice of his art until his death. His last work was a portrait of John Quincy Adams, which was finished by Sully. He had previously painted John Adams, Jefferson, Madison, Monroe, and most of the distinguished characters of the revolution and of the early period of the Union. His portraits of persons in private life are most numerous in Boston and its neighborhood, and these, like all his works, have lost nothing of their freshness or brilliancy through lapse of time. As a painter of heads he holds the first place among American painters, if we except Copley, and his flesh coloring rivals the finest efforts of any modern school. Upon the extremities of his figures, the draperies, and other accessories, he bestowed little labor, and they are sometimes finished in the most slovenly manner. He was superior to almost every other painter, according to Washington Allston, in "the faculty of distinguishing between the conventional expression which belongs to manners, and that

more subtle indication of the individual mind. It was this which enabled him to animate his canvas not with the appearance of mere general life, but with that peculiar distinctive life which separates the humblest individual from his kind." Stuart was a man of fine social qualities, and a most accomplished talker.

STUART, HENRY BENEDICT MARIA CLEMENT, Cardinal York, the last male representative of the Stuart family, born in Rome in 1725, died in Venice in 1807. He was the younger brother of the pretender Charles Edward, whom he was preparing to aid with a body of French troops assembled at Dunkirk, when the overthrow of the Jacobites at Culloden ruined the Stuart cause in Britain. He subsequently took orders in the Roman Catholic church, and in 1747 was appointed by Benedict XIV. a cardinal. On the death of his brother in 1788 he assumed the title of king of England as Henry IX., *gratia Dei, non voluntate hominum*, as the medal which he caused to be struck on the occasion declared. He was subsequently obliged to take refuge from French invasion in Venice, and during the last years of his life was dependent upon the British court for the means of subsistence.

STUART, JAMES, sometimes called Athenian Stuart, an English antiquary and architect, born in London in 1718, died Feb. 2, 1788. In early life he was a painter of fans, a branch of art then greatly in vogue, and to which he devoted himself until about 1742. For several years subsequent to this he resided in Rome, and in 1750 he accompanied Nicholas Revett on an antiquarian tour to Greece, remaining in Athens from March, 1751, to the close of 1758. Returning to London in 1755, he set about the preparation, in conjunction with his fellow traveller, of a work on the "Antiquities of Athens," of which the 1st volume appeared in 1762, and the 2d and 3d posthumously in 1790-'94. Subsequent to his return to England, Stuart was much employed in London as an architect.

STUART, JOHN, Earl of Bute. See BUTE.

STUART, MOSES, an American divine and author, born at Wilton, Conn., March 26, 1780, died at Andover, Mass., Jan. 4, 1852. He was graduated at Yale college in 1799, was employed for some time as a teacher, studied law, was admitted to the bar in 1802, and for the two succeeding years was a tutor in Yale college. He afterward studied theology, and was ordained pastor of the first Congregational church of New Haven, March 5, 1806. In 1809 he was appointed professor of sacred literature in the theological seminary at Andover, which office he held until 1848, when he resigned in consequence of the advancing infirmities of age. Beside 11 or 12 occasional sermons, and some other minor works, he published a "Grammar of the Hebrew Language without Points" (1818); "Letters to the Rev. William E. Channing containing Remarks on his Sermon recently preached and published in Baltimore" (1819);

a "Grammar of the Hebrew Language with Points" (1821); "Letters to Dr. Miller on the Eternal Generation of the Son of God" (1822); "Commentary on the Epistle to the Hebrews" (2 vols. 8vo., 1827-'8); "Hebrew Chrestomathy" (1829); "Essay on the Question whether the use of Distilled Liquors or Traffic in them is compatible at the present time with making a Profession of Christianity" (1830); "Letters to Dr. Channing on Religious Liberty" (1830); a "Commentary on the Epistle to the Romans" (1832); "The Mode of Christian Baptism prescribed in the New Testament" (1833); "A Grammar of the New Testament Dialect" (2d ed., improved, 1834); "Hints on the Prophecies" (2d ed., 1842); "Commentary on the Apocalypse" (1845); a "Letter to the Editor of the North American Review on Hebrew Grammar" (1847); "A Scriptural View of the Wine Question" (1848); a "Commentary on Daniel" (1850); "Conscience and the Constitution" (1851); a "Commentary on Ecclesiastes" (1851); and a "Commentary on Proverbs" (1852). Professor Stuart was distinguished for great quickness and versatility of mind, indomitable perseverance, noble and generous impulses, and an enthusiastic interest in every subject that engaged his attention.

STUCCO (Ital.), a name applied to the hard external finish given to the coat of plaster upon walls, sometimes consisting of fine lime and sand without hair, hand-floated twice and well trowelled (see PLASTERING); but the term is more properly applied to a hard finish prepared of a mixture of ground marble or chalk, with pure lime as a cement, in such proportions and so worked as to produce a durable and uniform surface susceptible of polish. This sort is adapted for covering walls and internal decorations; but for external work the mixture is made of coarser materials and with cements adapted to withstand the weather. Pulverized alabaster or gypsum is sometimes used instead of marble, mixed with rich lime, carefully slaked and sifted, and then trowelled on to a rough coat until the surface is perfectly smooth. A solution of gelatine or strong glue or gum arabic is sometimes used instead of water to render the preparation more durable, and metallic oxides are added to produce desirable tints. The cements or stuccoes known in England as Keene's, Martin's, and Parian are made of plaster of Paris, mixed with a saturated solution either of alum, sulphate of potash, or borax, then dried in the air, and baked at a dull red heat. The preparation is pulverized and sifted, and is finally slaked with a solution of alum. Martin's is made with pearlash as well as alum, and is baked at a higher heat than the others. When the surface is perfectly dry, it may be polished by rubbing with fine grit stones, followed by tripoli powder, chalk, and oil. The application described in the article SOAGLIOLA is a variety of stucco.

STUHL-WEISSENBURG (Hung. *Székes Fejérvár*), a town of Hungary, capital of the

county of the same name, situated on the left bank of the Osorgó, near the border of an extensive morass, 88 m. S. S. W. from Buda; pop. 22,800. The principal buildings are the cathedral and the episcopal palace. There are manufactures of woollen and linen goods, hardware, and several other articles. The kings of Hungary were formerly crowned here, and the cathedral contains many of their tombs.

STURGEON, the name given to the cartilaginous fishes of the class of ganoids and family *sturioides*. The body is elongated and fusiform, covered with a rough skin protected by 5 longitudinal rows of tubercular plates; the largest of these rows is along the back, and there is also one on each side, and one from each pectoral to the ventral fins; the plates are flattened, and marked with radiating striae. The head is depressed, and ends in a long triangular snout covered with bony plates; mouth funnel-shaped and protrusible, on the under surface, without teeth, having in front a few depending barbels, evidently organs of touch; gill covers very large and gills free; pseudo-branchiae and spiracles are present, but no branchiostegal rays; fins well developed, the dorsal and anal opposite and behind the ventrals; tail heterocercal or unsymmetrical, the vertebral cord being prolonged into the upper lobe as in the sharks, and strengthened by fulcra along its upper margin; a soft caudal on the under surface of the tail. The vertebral column consists of an undivided soft *chorda dorsalis*; the air bladder is very large, communicating freely with the oesophagus; there is a spiral valve in the intestine, and a conglomerate pancreas. They are generally of large size, inhabiting the northern temperate seas of both coasts of America, eastern Europe, and western Asia, from which they ascend the rivers in spring for the purpose of spawning, returning to the salt water in autumn; species are also found in the great American fresh water lakes, which never descend to the sea. They are oviparous; the food consists of any soft substances which they stir up from the bottom with their snouts, and of small fish; they have a habit of jumping out of water, generally considered for mere sport, but most likely to disengage from their gills and bodies the lampreys which eat into their flesh.—The genus *acipenser* (Linn.) has the characters of the family. The common sturgeon of Europe (*A. sturio*, Linn.) attains a length of 6 to 10 feet, and sometimes more; it is found in the Caspian and Black seas and the rivers opening into them, and sometimes on the coasts of Great Britain and the Baltic; the flesh is delicate, compared to veal, and was in old times considered a royal dish; it was served with great pomp in ancient Greece and Rome, but in modern days is held in far less esteem; still it is largely consumed in Russia, fresh, salted, and pickled. A larger species, also found in the seas and rivers of S. E. Europe, is the beluga (*A. huso*, Linn.), attaining a length of 12

to 15 feet and a weight of 1,200 lbs., and occasionally of much larger size; it ascends the rivers opening into the Caspian and Black seas, with other and smaller species. The flesh is tough and of inferior quality; the sound or air bladder furnishes an abundant supply of isinglass, for which great numbers are caught in Russia. (See GELATINE, vol. viii. p. 128.) Caviare is also made from the roe of the female, which sometimes constitutes $\frac{1}{4}$ of the weight of the fish; the skin is used for harness leather, and the dorsal cord, cut in pieces and dried, is used as food. The sterlet (*A. ruthenus*, Linn.), found in the Caspian, and growing to a length of 2 or 3 feet, furnishes a most delicate food and the best caviare. Some idea of the commercial importance of this fishery may be gathered from the fact that in 1829, in the Caspian sea alone, about 8,800 persons were employed, obtaining 786,000 sturgeons, yielding 28,500 lbs. of caviare and 1,100 lbs. of isinglass; the fish are taken in nets as they go up to spawn. The color in these species is brown of various shades, the plates whitish, and the abdomen silvery.—In North America sturgeons do not inhabit the rivers flowing into the Arctic ocean, and are not found north of the watersheds between lat. 58° and 54° N., where the mean annual temperature is about 88° F.; they seldom enter clear cold streams, but ascend muddy rivers in such numbers that many large Indian tribes subsist entirely on their flesh in summer; each watershed has its own species, varying in some minor characters. The sharp-nosed sturgeon (*A. oxyrinchus*, Mitch.) attains a length of from 8 to 7 feet; it is found on the coasts of New England, New Brunswick, and Nova Scotia; it is common in Long Island sound from the middle of June to October, and is taken by harpoon and in nets; the smaller specimens are esteemed for the table; it is grayish brown above, silvery on the sides, and white below. The lake sturgeon (*A. rubicundus*, Lesueur) is olive brown above, white below, with the fins reddish; it attains a length of 4 feet, and is found in the great lakes and in the Ohio river. The short-nosed sturgeon (*A. brevirostris*, Mitch.) is dusky above and white below; the snout is short and blunt; it attains a length of 2 to 5 feet, and is so common in the Hudson that its flesh in the market has been known as Albany beef; it much resembles the *A. sturio* of Europe. Other species are described from the northern waters, the rivers of the N. W. coast, and from Lake Superior, by Richardson and Agassiz.—The genus *polyodon* (Lacép.) or *spatularia* (Shaw) has the general form of *acipenser*, but is without the bony plates on the body and head; the snout is very much elongated, and compressed into a thin leaf-like organ, partly bony and partly cutaneous, sometimes nearly as long as the body; gill covers very large, extending far back in a membranous point; the mouth is wide, with numerous minute teeth in the young

animal, which are lost with age. The spoon-bill sturgeon (*P. folium*, Lacép.) is steel-blue above and white below; it attains a length of 5 feet, and is found in the Mississippi, Ohio, and their tributaries; it is also called shovell fish and paddle fish; the flesh is occasionally eaten, but is rather tough; the singularly shaped snout is used to shovel up the mud in search of food. The genus *platirostra* (Les.) is probably only the adult of *polyodon*, the principal difference being the absence of teeth.

STURLESON. See SNORRO STURLESON.

STURM, JOHANN, a German philologist, born at Schleiden, now in Rhenish Prussia, Oct. 1, 1507, died in Strasbourg, March 8, 1589. He studied at Liège in the college of St. Jerome, and in 1524 went to Louvain, where he spent 5 years, and, in partnership with Rudiger Rescius, established a press, and printed some Greek works. In 1529 he went to Paris, and there read public lectures on Greek and Latin writers and on logic; and thence in 1537 to Strasbourg to become rector of its newly established gymnasium, which, under his administration for 45 years, acquired great celebrity, and in 1586 was converted into a university. The system of education introduced by him, aiming chiefly at thorough Latin scholarship, exerted great influence throughout Germany, and was the model of that adopted by the Jesuits. He was several times employed by government in a diplomatic capacity. He was a Lutheran, but liberal to all who suffered for religious opinions, and was by the persecution of stricter sectarians finally driven from the head of his school. His works are very numerous, and are principally devoted to the elucidation of classic authors. His work on a system of education, *De Literarum Ludis recte aperiendis Liber* (4to., Strasbourg, 1538), has been several times reprinted.

STUTTGART, a town of Germany, capital of the kingdom of Württemberg, situated on the river Nesen, a tributary of the Neckar, 88 m. E. S. E. from Carlsruhe and 97 m. S. E. from Frankfort; pop. in 1858, 51,655. It stands in a very beautiful valley surrounded by vine-clad hills, with well wooded mountains in the distance. The town is encircled by a wall and ditch, is entered by 8 gates, and consists of two parts, the ancient and modern, with two suburbs. In the chief square is a fine old Gothic church with a high tower, and many ancient sculptures and monuments of the princes of Württemberg. The royal palace, begun in 1746 and finished in 1806, is a large building of freestone splendidly decorated and furnished in the interior; and the old palace, completed in 1570, resembles a feudal castle, and is now occupied by officials connected with the government. In the same square is a monument to Schiller by Thorwaldsen. The hospital church is a Gothic building, finely decorated in the interior, and contains the grave of Reuchlin. The town hall was built in the 15th century. The other public

buildings and institutions of importance are the museum of natural history; a library of 200,000 volumes and 8,220 MSS.; a cabinet of medals containing about 17,000 specimens; a museum of the fine arts, with many valuable statues and pictures; a bazaar, and a theatre. Stuttgart has a gymnasium, military academy, polytechnic school, school of art, numerous schools, hospitals, asylums, and other charitable institutions, and extensive barracks and government offices. The manufactures include woollen, silk, linen, and cotton goods, jewelry, musical and philosophical instruments, leather, and tin ware. The book trade is extensively carried on, and connected with it are numerous paper mills, type foundries, lithographic establishments, and printing offices. The town has railway communication with all the principal places of Europe, and the Neckar is navigable. A considerable trade is carried on in different manufactured articles, and bark. In the vicinity are numerous parks and gardens, where the public are admitted, including Rosenstein, the summer palace of the king; and Kannstadt, about 8 miles distant, is resorted to by the citizens and visitors as a favorite watering place.—Stuttgart is a very ancient town, but the date of its foundation is not known. It suffered severely during the wars of the 16th and 17th centuries. Though repeatedly occupied by both sides during the wars of Napoleon, it escaped with little loss.

STUYVESANT, PETERUS, the last Dutch director-general of New Netherlands (New York), born in Holland in 1602, died in New York in Aug. 1682. He served in the war in the West Indies, became director of the colony of Curaçoa, and, having lost a leg in an unsuccessful attack on the Portuguese island of St. Martin, returned to Holland in 1644. In 1645 he was appointed by the Dutch West India company director-general of New Netherlands, succeeding William Kieft, whose conduct had involved the settlers in a bloody war with the Indians, and created general disorder in the colony. He did not arrive till May, 1647, when he commenced a vigorous and often arbitrary administration, conciliating the savages and restoring order in every department. In 1650 he arranged at Hartford with the New England commissioners a line of partition between the Dutch and English territories, which had previously been undefined and a cause of frequent disputes. He was also involved in trouble with the Swedes on the south. In 1651 the Dutch built Fort Casimir on the Delaware, which was captured by Rising, the governor of New Sweden, in 1654. To revenge this wrong, Stuyvesant in 1655, with 7 vessels and between 600 and 700 men, sailed into the Delaware, and made a conquest of the whole settlement. Ten years of peace followed, disturbed only by the growing jealousy of the English, and by the civil discontents which the arbitrary character of Stuyvesant's administration tended somewhat to inspire. In 1658 a convention of the people,

consisting of two deputies from each village in New Netherlands, had met and demanded that "no new laws shall be enacted but with the consent of the people; that none shall be appointed to office but with the approbation of the people; that obscure and obsolete laws shall never be revived." This assembly was dissolved by the governor, who commanded the members to separate on pain of punishment, telling them in his farewell message: "We derive our authority from God and the company, not from a few ignorant subjects." The spirit of resistance nevertheless increased, and was fostered by the large number of English settlers who had come to reside within the limits of New Netherlands. The encroachments of the New England colonies at last induced Stuyvesant himself to repair to Boston and lay his remonstrances before the convention of the united colonies, which met with but little favor; and a second embassy to Hartford had no better success. The Connecticut agents made exorbitant claims to territory by virtue of the royal patent. "In case there was another royal patent," said the Dutch commissioners, "between where would New Netherlands then lie?" "We know of no New Netherlands, unless you can show a patent for it from his majesty," was the cool reply. In 1664 Charles II. granted to his brother, the duke of York, the territory from the Connecticut river to the shores of the Delaware, and an English fleet under Richard Nicolls appeared in the bay in August and demanded the surrender of the city. Stuyvesant was unwilling to capitulate, but the municipality, seeing the futility of resistance, insisted on yielding. After holding out for a short time, the governor at last consented, and the city was given up on Sept. 3, 1664. After the capture Stuyvesant went in 1665 to report to his superiors in Holland, and afterward returned, spending the remainder of his life on his farm or *douwerij* (whence the name of the street called the Bowery), then outside the limits of the city. He lies buried in the vaults of St. Mark's church in 10th street.

STY (*Lat. hordeolum*, from *hordeum*, barley), a small inflammatory tumor on the edge of the eyelid, about the size of a grain of barley. Sty has its seat in the cellular tissue at the margin of the lid, involving generally the roots of one or more of the eyelashes. The tumor is furuncular in character, and almost invariably goes on to suppuration; its progress is sometimes tedious and the suppuration imperfect. Sty is most common in persons of a strumous habit, and often has for an exciting cause derangement of the digestive organs. By attending to the condition of these organs the recurrence of the disease may be most generally prevented. When the little tumor has made its appearance, it is best to promote its maturation by warm and emollient fomentations. It is commonly advisable to leave it to burst of itself; but when maturation has occurred, if it occasion much uneasiness, it may be punctured.

STYLE, OLD AND NEW. See CALENDAR.

STYLITES (Gr. *στυλίτης*, belonging to a pillar), SIMMON, a Syrian who lived in the first half of the 5th century, known in church history for having inaugurated a new kind of asceticism. He left his convent, and for 9 years lived under the open sky on a pillar, the top of which was only 2 cubits in circumference. Finally he ascended a pillar 20 yards in height, on which he lived for 30 years, and preached with remarkable effect to the crowds who gathered around him. The people of Antioch received his body into their city, and revered him as their patron saint. His example found several imitators in the East until the 19th century. In the West asceticism of this kind was little encouraged by the ecclesiastical authorities.

STYRIA (Ger. *Steiermark*), a duchy and crown land of Austria, bounded by Upper and Lower Austria, Hungary, Croatia, Carniola, Carinthia, and Salzburg; area, 8,664 sq. m.; pop. in 1857, 1,056,773. It is divided into the circles of Gratz, which contains the capital of the same name, Marburg, and Bruck. A great part of the surface is mountainous, being traversed by three chains belonging to the Noric branch of the Alpine system, the highest summits of which are on the N. W. and S. W. frontiers, their culminating points, Grossenberg and Eisenhut, being respectively 8,881 and 7,676 feet above the sea. In the S. and E. part the mountains are of moderate height, and some of them separated by extensive valleys. The N. W. part is known as Upper Styria, and the country in the opposite direction as Lower Styria. The surface belongs to the basin of the Danube, toward which the drainage flows by numerous tributaries; the most important of these are the Mur, Enns, Raab, Save, and Drave, all of which, except the Raab, are navigable for boats. There are numerous small lakes, but none of any considerable size, and several cold, hot, and mineral springs. Limestone, sulphur, alum, rock salt, gold, silver, lead, copper, cobalt, zinc, and iron ore of superior quality, are all found. In the more elevated districts the climate is cold, but in the valleys it is mild and agreeable. The soil in the valleys is generally fertile, but the grain produced is barely sufficient for the consumption of the population. The vine thrives well in the valleys and on lower slopes. The mountains are generally clothed to their summits with timber, and the forests cover about half the surface. The inhabitants are mostly of German origin, but the Slavic Vindes or Sloventzi are also numerous; nearly all are Roman Catholics. Iron is extensively manufactured, and some of the mines were known to the Romans. Some linen, cotton, woollen, and silk goods are also manufactured; but the most important branch of industry is the felling and rafting of timber. Several millions of jews-harps are annually exported. An important transit trade between Italy and Germany is carried on, and is greatly facilitated by good roads, and by the Vienna

and Trieste railway, which crosses the Semmering mountains.—Under the Romans the eastern part of Styria belonged to the province of Pannonia, and the western to Noricum. Christianity was introduced in the 4th century, but the northern barbarians afterward overran the province. Styria was annexed to Austria in 1192, was subsequently attached to Bohemia, and wrested from King Ottocar II. by Rudolph I. of Hapsburg, a possession of which house it has since remained.

STYX (connected with Gr. *στυγναι*, to hate, abhor), in Greek mythology, the chief river of the lower world, around which it flows 7 times. The name was said to be derived from the nymph Styx, the daughter of Oceanus, who, when Jupiter prepared to wrest the power from the hands of Saturn and the Titans, was the first of the immortals to answer to his call, coming with her 4 sons to his assistance. For her readiness he made her children his constant attendants, and upon her he conferred the distinction of being the oath-sanctioner of the gods. When a god was about to take the oath, a cup of water from this stream was brought him by Iris, and while pouring out this he took the oath. In the Hesiodic theogony Styx is called the daughter of Oceanus and Tethys. She was the mother of Zelos (zeal), Nike (victory), Bia (strength), and Cratos (power).

SUABIA. See SWABIA.

SUAREZ, FRANCISCO, a Spanish scholastic theologian, born in Granada in 1548, died in Lisbon in 1617. He early entered the order of the Jesuits, was in succession professor at the universities of Alcalá, Salamanca, Rome, and Coimbra, and one of the most prolific theological writers of his age. Benedict XIV. and Bossuet accounted him among the most learned theologians of their church, and Grotius called him a profound theologian and philosopher, with whom but few could be compared. His work, *Defensio Fidei adversus Anglicana Secta Errores*, was ordered by the parliament of Paris to be burned by the public executioner, because it claimed for the pope a coercive power over kings. The complete works of Suarez were published at Lyons, Mentz, and Venice, in 28 vols. fol., the last named edition in 1748, and a new edition is now (1862) in course of publication at Paris. The Jesuit Noël published extracts from them in 2 vols. fol. (Geneva, 1782). A life of Suarez was written by Deschamps (Perpignan, 1871).

SUBJECTIVE. See OBJECTIVE AND SUBJECTIVE.

SUBLIMATION, a process of distillation in which the vapors condense in a solid form. It takes place naturally in volcanic fissures and craters, and the products, often of a sulphurous character, are deposited upon the walls. Deposits thus formed are termed sublimate. A great variety of mineral substances are subject to vaporize by heat and become solid again on cooling; and the number of such increases with the increased degree of heat which

we can apply. Some vegetable substances also possess the same property, as camphor, benzoic acid, &c. Sublimation is much employed in the arts and manufactures as a means of separating volatile from fixed bodies, usually for obtaining the former in a purer state. The vapor is sometimes chemically changed by contact with the oxygen of the air, and the sublimate is then of a different composition from the original body, as when oxide of zinc is produced by subjecting the metal or its ores to heat exposed to the air.

SUBLIME PORTE (Fr., lofty or magnificent gate), the title officially given to the Ottoman government, and also applied to the edifice in which state affairs are transacted. Orkhan (1826-'57), the first Turkish sultan who adopted the title *padishah*, erected a magnificent palace with an imposing entrance, on which he bestowed the name of "Sublime Porte," which from that time to the present has been applied to the monarch and government ruling there. This use of the term also had its origin partly perhaps in the oriental custom of transacting public business at the gate of the city or palace.

SUBMERGED FORESTS. See FORESTS, SUBMERGED.

SUBPCENA, a judicial process directed to a witness commanding him to appear at the court, to testify what he knows in the case therein described, pending in the court, under a certain penalty (*sub pcena*) mentioned in the process. If the court wishes to examine any books or papers which are in possession of the witness, a clause is inserted in the writ bidding him to bring them with him; and the subpcena is thence called a *subpcena duces tecum*. A subpcena ought always to be served at a reasonable time before the trial, in order that the witness who is summoned thereby may have time to arrange his affairs in contemplation of his absence, and may have convenient time to reach the court. The statutes generally regulate the matter, and usually require that for every certain number of miles distance, one day shall be added in estimating the time of service. The manner of service is also often prescribed by American statutes. In New York, for example, the mode of service is to show the subpcena to the party; to deliver to him a copy of the process, or a ticket containing the substance of it; and to pay or tender to him the amount allowed by law for travelling to and returning from the place at which he is required to attend, and his fees for one day's attendance. These fees for travel and daily attendance are also matter of express statutory provisions, and they differ in the different states. The subpcena ought to be served upon the witness personally, for otherwise he cannot be proceeded against as for a contempt if he neglects to appear. Service may be made by any person, and is proved generally by affidavit, or, if it be made by a sheriff or his officer, by a simple return or certificate of service. When a witness has been duly summoned, and his fees have been paid or

tendered, or payment or tender has been waived, he is guilty of a contempt of court if he fails to appear at the appointed time, and may be proceeded against by attachment. The process of attachment rests not on the ground of any actual damage resulting from the party's failure to appear, but is given for the vindication of the dignity of the court; and if it be clearly shown that the court's process was wilfully disobeyed by the witness, he is condemned to fine or imprisonment, or whatever other punishment is ordered by statute for the offence. In Massachusetts, and probably in other states, the party actually injured by the non-appearance of the party summoned has a statutory action for all damages caused by his default.—The office of the subpoena at common law is simply to bring into court a witness whose evidence is sought. Chancery, borrowing the name of the writ, but giving it a far larger scope, issued it in order to compel a defendant in a cause to appear and answer upon oath the plaintiff's allegations. This sort of subpoena was invented or first used in chancery by John de Waltham, bishop of Salisbury, master of the rolls under Richard II.; the commons complained "of his subtlety" "as contrary to the course of the common law." It was in fact the cause and subject of some of the loudest complaints against the chancery jurisdiction; but it was finally acquiesced in and became the most effective process of the chancery courts, and thereby the means of much of its beneficent action. The prayer for the subpoena is usually included in the closing clause of the bill, and asks that the defendant "may be required to appear, to answer the bill and to abide by the decree of the court."

SUBSCRIPTION, in law, a contract by which one agrees to contribute with others for a common purpose. The word is sometimes applied to the sum of money subscribed. The contract of subscription depends for its validity upon the same principles and facts as other contracts. The subscribers may be sued for their subscriptions whenever the conditions upon which they have promised to pay are fulfilled, if the purpose of the contract is a legal one, and founded upon a good consideration, and if there is a party capable of maintaining the action. Subscription papers, however, are often hastily drawn up and carelessly expressed; no party is named to whom the amounts subscribed are to be payable; it is merely agreed to contribute certain sums to a specified object, leaving the mode of collecting these sums to be afterward provided for; and the inducement to subscribe is commonly either a benevolent object or the hope of future profit, without any immediate legal consideration. In short, the difficulty in the way of enforcing contracts of subscription has arisen frequently, we may say indeed chiefly, from the want of proper parties and of a valid consideration for the promise. In their disposition to uphold this class of contracts, if they can be upheld consistently with the rules of

law, the courts have gone in some cases so far as to say that the subscribers to a common object may be treated as contracting with each other, the consideration of each subscription being the promises of the other contributors, each subscriber being thus liable to a suit by all the others. This doctrine however is against the weight of authority; and it may be regarded as pretty well settled that no action can be maintained on a subscription unless it is made in favor of some particular person or corporation in existence at the time, and capable of bringing a suit upon it. Thus it has been held that a subscription to the stock of a corporation to be afterward formed did not render the subscriber liable to a suit by the corporation after it had been chartered and organized. But where the subscription paper named a party who was to collect the sum subscribed, it was held that he might bring a suit against a subscriber. So when the paper provided that the money should be paid to a person to be appointed by the subscribers in a prescribed manner, it was held that such person, when so appointed, might sue on the subscriptions. And it has been held that a subscription for a good consideration, but which could not be sued for want of a party to whom the promise was made, may be the consideration for a promissory note payable to a party capable of bringing an action. There are many cases which hold that no action can be maintained upon a mere voluntary subscription for a charitable or other purpose, upon the ground that there was no legal consideration for the promise; and these cases would seem to be in accordance with the rule of law requiring an actual consideration for a promise in order to make it legally binding. There are other decisions, however, which undertake to raise a consideration from the promises of the other contributors; from the acts done and expenses incurred on the faith of the subscription; and from the express or implied promise or legal liability of the parties, in whose favor the subscription is made, to carry out its purposes. Where, by the express terms of the subscription, the promisee agrees to appropriate the funds to a particular object and in a particular way, upon the well settled principle of mutuality of contracts, his promise is a good consideration for that of the subscribers. Whether, however, the merely legal and implied liability of a charitable corporation or board of trustees to appropriate the funds subscribed in accordance with the provisions of their charter or trust is a sufficient consideration, without an express promise in the subscription paper, to support an action on a subscription in their favor, is a question on which there is some conflict of opinion. Subscriptions which rest on an express contract by the promisee to do some act beneficial to the subscriber, are in fact but ordinary contracts.

SUCCOORY. See **CHICOORY**.

SUCHET, LOUIS GABRIEL, a French general, born in Lyons, March 2, 1772, died in Mar-

seilles, Jan. 8, 1826. He entered the national guard of Lyons in 1791 as 2d lieutenant of cavalry, became a chief of battalion, was present at the siege of Toulon in 1793, and was then transferred to the army of Italy. He received the rank of chief of brigade on the battle field at Neumark in April, 1797. He was selected as one of the commanders in the army of Egypt, but was detained by Brune as major-general in the army of Italy, in which he reestablished order and discipline; afterward served as chief of staff under Masséna on the Danube, and again in Italy, where after Masséna took the command he was made general of division, and during the siege of Genoa, with a far inferior force, secured the capture of 15,000 Austrians with 6 standards and 83 cannon. He took part in the battle of Marengo and in the passage of the Mincio, and commanded the centre of the army of Italy at Bozzolo, Borghetto, Verena, and Montebello. In 1805 he commanded the left wing under Marshal Lannes at Ansterlitz, and in 1806 took an important part in the battle of Jena. In 1808 he was made commander of a division in the army of Spain, and by his siege of Saragossa (1809), the taking of Lerida (1810), Tortosa and Tarragona (1811), and the occupation of Montserrat, won the baton of a marshal of the empire in 1811. He afterward took Oropesa, Murviedro, and Valencia, which place he entered Jan. 14, 1812, capturing 18,000 Spanish troops and immense stores, and was rewarded with the title of duke of Albufera and a large revenue. His justice and moderation gained him the affection of the Spaniards, and on the withdrawal of the French from Spain he left the country with honor. Louis XVIII. made him a peer of France in 1814. He wrote *Mémoires sur la guerre d'Espagne, 1808-1814* (2 vols. 8vo., Paris, 1829).

SUCKER, the popular name of the soft-rayed fishes of the carp family (*Cyprinidae*) included in the genus *Catostomus* (Lesueur). They are characterized by a single dorsal, 8 rays in the gill membrane, smooth head and gill covers, jaws without teeth and retractile, mouth beneath the snout, and lips plaited or lobed suitable for sucking; there are comb-like teeth in the throat; the intestine is very long, and the air bladder divided into 2 or more parts. There are about 80 species in the fresh water rivers and lakes of North America; they feed on aquatic plants, worms, larvae, and mollusks, and rarely take bait; they are very tenacious of life; the young are devoured by kingfishers, fish hawks, and carnivorous fishes. The common sucker (*C. Bostoniensis*, Les.) is 8 to 15 inches long, of a brownish color, olive on the head, reddish with metallic lustre on the sides, and white below; it is common in New England and the middle states. The chub sucker (*C. gibbosus*, Les.) is 7 to 12 inches long, dark brown above, golden greenish yellow on the sides, anterior part of abdomen whitish, and fins dark; body convex in front of dorsal, and

sides of head sometimes spiny or tuberculated; it is common in the ponds of the New England and middle states. The gray sucker (*C. Hudsonius*, Les.) is grayish above, and 18 to 21 inches long; it is found in rivers opening into Hudson's bay, in Columbia river and its tributaries, and in the fur countries. Other large species from the northern regions have been described by Richardson and Agassiz. Among the larger species of the western rivers are the Missouri sucker (*C. elongatus*, Les.), 2 to 3 feet long, in the Ohio river, black on the back, and hence called black horse and black buffalo; and the buffalo sucker (*C. bubalus*, Raf.), of about the same size, in the Ohio, Mississippi, Missouri, and their tributaries, brownish above, bronzy on the sides, and whitish on abdomen. These and other species are frequently used as food in the West.

SUCKING FISH, the popular name of the remora, a spiny-rayed fish of the genus *Echeneis* (Linn.), so named from the Greek *εχεναι*, to hold, and *ναυς*, a ship. This genus was placed by Cuvier among the malacopterygians, near the cod family; Müller ranked it among the *disco-bolæ* (lump fishes), with the goby family; Agassiz considers it as belonging with the scomberoid or mackerel family. The body is elongated, tapering behind, covered with very small scales; there are 4 perfect branchiæ; very small teeth on jaws, vomer, and palate, crowded and hardly distinguishable posteriorly; mouth small and horizontal, the lower jaw the longer; eyes above the angles of the mouth; ventrals thoracic, narrow, united only at the base, and apparently not used for attaching the animal to submarine bodies; head flattened. Above the head and anterior dorsal vertebra is an oval disk, presenting from the middle to both sides oblique transverse cartilaginous plates, arranged like the slate of a Venetian blind; on the middle of the under surface are spine-like projections connected by short bands with the skull and vertebrae, and their upper margin is beset with fine teeth. According to De Blainville, this organ is an anterior dorsal fin, whose rays are split and expanded horizontally on each side instead of standing erect in the usual way. By means of this apparatus, partly suctorial and partly prehensile by the hooks, these fishes attach themselves to rocks, ships, and the bodies of other fishes, especially to sharks. The dorsal is opposite the anal, but the fins are weak, and these fishes accordingly adhere to sharks and other moving bodies, which transport them to places where food is abundant, and often from the tropics to temperate regions. There are 6 or 8 pyloric appendages, but no air bladder. The common sucking fish of the Mediterranean, so well known to the ancients (*E. remora*, Linn.), is from 12 to 18 inches long, shaped somewhat like a herring, dusky brown above and lighter below; it has 17 or 18 plates on the head; it occurs in the Atlantic ocean, on the British coasts, and has even wandered to the American

shores. The Indian remora (*E. nauaratus*, Linn.) attains a length of 2½ feet; it is olive brown above and whitish on the sides, and has 23 to 34 plates in the sucking disk; it is found in the Atlantic, on the American and African coasts, in the Red sea, Indian ocean, and even around Japan. On the Mozambique coast it is put to a practical use in catching marine turtles; a number are taken to sea in a vessel of water, and are put overboard when a turtle is seen, a rope fastened to a ring having been attached to the tail; in the instinct to escape they attach themselves to the nearest turtle, and both fish and reptile are hauled in together. The *E. lineata* (Bloch), of the tropical Pacific, has a very elongated body and only 10 sucking plates. Peculiar to the American coast is the white-tailed remora (*E. albicauda*, Mitch.); it is from 1 to 2 feet long, grayish slate above, with dark band on sides; the disk has 21 plates; it is not uncommon on the southern shore of Massachusetts and in Long Island sound, where it is generally called shark sucker. None of the species feed upon the fish to which they are attached, but upon small floating animals. For other sucking fish, adhering by means of the ventral fins, see LUMP FISH.

SUCKLING, SIR JOHN, an English poet and dramatist, born in Whitton, Middlesex, in 1608 or 1609, died in Paris probably in 1642. He was the son of the comptroller of the royal household under James I., and was educated at Trinity college, Cambridge. Succeeding to an immense fortune at the death of his father in 1627, he travelled for a while on the continent, and in 1631-2 served as a volunteer in the forces under Gustavus Adolphus. Returning to England, he became one of the most brilliant ornaments of the court of Charles I., and was distinguished not less for his wit and gallantry than for his passion for gambling. At the breaking out of disturbances in Scotland in 1639 he equipped a body of 100 horse for the royal service, at a cost, it is said, of £12,000, but was disgraced by the pusillanimous conduct of himself and his men in an encounter with the Scots near Dunse, for which he was mercilessly ridiculed by the rival wits of the time. In the succeeding year he was elected to the long parliament; but, having joined in a plot to rescue Strafford from the tower, he was compelled to take refuge in France. His literary remains comprise 4 plays, a number of short poems dedicated to love and gallantry, a treatise on "Religion by Reason," and a collection of letters. His reputation at the present day rests almost entirely upon his poems. His works were published by Tonson in 1709, and in 1836 appeared "Selections from his Works," with a memoir by the Rev. Alfred Suckling.

SUORE, ANTONIO JOSÉ DE, a South American general, born in Cumana, Venezuela, in 1793, assassinated in the neighborhood of Pasto, in Ecuador, in June, 1830. He entered the insurrectionary army in 1811, serving under Miranda, and afterward under Gen. Piar. In

1819 he attained the rank of brigadier-general, and was appointed to negotiate a suspension of hostilities with the Spanish general Morillo. He was not long after promoted to the command of a division sent from Bogota to assist the province of Guayaquil. Though repulsed at Huachi, he succeeded in the autumn of 1821 in effecting a favorable armistice with the royalist general Aymerich, and thus enabling the Peruvian division to form a junction with the Colombians. In May, 1822, he achieved the decisive victory of Pichincha, which was immediately followed by the capitulation of Quito. Having returned to Bogota, he was despatched early in 1823 as Colombian envoy to Lima, with an auxiliary Colombian army of 8,000 men. He found Lima in the hands of the royalists, and retired to Callao, where he was besieged till the successes of Gen. Santa Cruz in the south of Peru compelled the royalist general to evacuate Lima in July, 1823. Sucre attempted to coöperate with Santa Cruz, but the defeat of the latter rendered his return to Callao necessary. Bolivar soon after took the command of the liberating army in person, but after the battle of Junin relinquished it to Sucre, who, on Dec. 9, 1824, fought and won the battle of Ayacucho, the most brilliant battle ever fought in South America, capturing the Spanish viceroy La Serna, killing and wounding 2,600 royalists, and the next day receiving the surrender of Gen. Canterac, the Spanish commander, with 15 general officers and the whole army prisoners of war. Three days later he entered Ouzco in triumph, and immediately proceeded against Olaneta, who with a small body still held Upper Peru against the republicans. The death of Olaneta in April, 1825, placed both Upper and Lower Peru in Sucre's hands, and he assembled as speedily as possible a congress at Chuquisaca, which, in Aug. 1825, decided to form the new republic of Bolivia, to request Bolivar to draw up a constitution for them, to call their capital Sucre, and to invest the government for the time being in Gen. Sucre with the title of "captain-general and grand marshal of Ayacucho." In 1826 a new congress assembled to receive the constitution prepared by Bolivar, and Sucre resigned his captain-generalship, but was at once elected president under the new constitution. The revolution in Peru in 1827, which overthrew the government of Bolivar, exerted an unfavorable influence in Bolivia, and an insurrection took place in which Sucre was attacked and dangerously wounded. On his recovery in Aug. 1828, he resigned and returned to Colombia, but was at once made commander of the Colombian army of the south, and political chief of the southern departments of the Colombian republic. In this capacity he led his troops in a series of military operations which terminated in the defeat and capitulation of the Peruvians under Gen. La Mar at Tarqui, Feb. 26, 1829. He became a member of the constituent congress of 1830,

and it was on his return to Quito from the session of that body that he was assassinated.

SUDORIFICS. See **DIAPHORETICS.**

SUE, EUGÈNE, a French novelist, born in Paris, Dec. 10, 1804, died in Annecy, Savoy, July 3, 1857. The son of a surgeon in the imperial guard, his sponsors at baptism were the empress Josephine and Prince Eugène Beauharnais. He studied medicine, and was early appointed assistant surgeon in the royal body guard. In 1823 he followed the French army to Spain, and saw the siege of Cadiz and the taking of the Trocadero; was afterward transferred to the medical service in the navy, and in 1827 was present at the battle of Navarino. Inheriting a competence on his father's death, he gave up his profession to devote himself to painting and literature. His first works were the sea novels *Kernock le pirate* (1830), *Plick et Plock* (1831), and *Atar-Gull* (1831), beside a number of shorter tales collected under the title of *La Coucaratcha* (4 vols. 8vo., 1832-'4). These were printed at his own expense, and notwithstanding their immoral tendency and coarse style, their vivacity rendered them popular. An affectation of Byronic scepticism shone conspicuously in his *Salomandre* (1832), which met with decided success, and in his *Vigie de Koatven* (1833). In all these performances the author seems to delight in presenting vice triumphant and virtue persecuted and derided. Although ill prepared for such a task, he now appeared as a historian, and under the patronage of the government published the *Histoire de la marine Française au 17^e siècle* (5 vols. 8vo., 1835-'7), which was a failure. *Cécile* (1835), one of his best novels, was followed by *Le marquis de Létorières* (1839) and *Jean Cavalier* (1840). He now assumed the advocacy of socialistic ideas and of the improvement of the condition of the lower classes. This change did not appear clearly in *Mathilde, ou mémoires d'une jeune femme* (6 vols. 8vo., 1841), an affecting narrative in which vice meets with retribution, but shone conspicuously in *Les mystères de Paris* (10 vols. 8vo., 1842), a work which, though presenting terrible pictures of vice and corruption, was for a while the most popular novel ever published, numberless editions being issued in France, and translations appearing in nearly all the European languages. *Le Juif errant* (10 vols. 8vo., 1844-'5) was still more objectionable, but was scarcely less successful on account of its being a merciless attack upon the Jesuits. These three novels respectively appeared at first in the *Presse*, the *Journal des débats*, and the *Constitutionnel*; they were followed by *Martin, l'enfant trouvé* (12 vols. 8vo., 1847) and *Les sept péchés capitaux* (16 vols. 8vo., 1847-'9). After the revolution of Feb. 1848, he undertook a serial work in which he held up aristocracy, monarchy, and the clergy to execration by narrating the sufferings of a proletarian family through ages, entitled *Les mystères du peuple*, which was continued from 1850 to 1856, and, being prosecuted for immo-

ality and sedition, was suppressed in 1857. He wrote numerous other novels, and alone or in conjunction with others dramatized several of his works, but with indifferent success. In 1848 he was defeated as a candidate for the constituent assembly; but in 1850 was elected, after a lively contest, one of the deputies for the department of the Seine. He sat among the members of the mountain, but never spoke. On the *coup d'état* of Dec. 2, 1851, he was expelled from France, and retired to Annecy.

SUETONIUS TRANQUILLUS, CAIUS, a Roman historian, born about A. D. 70, died probably in the latter part of the reign of the emperor Hadrian. He was the son of a military tribune, and appears, through the influence of his friend the younger Pliny, to have obtained a similar office, which his love of letters induced him to transfer to a relative. Pliny subsequently helped him to become *magister epistolarum*, an office of considerable importance in the imperial household, and which gave the incumbent many opportunities of examining the state archives. From this position he was removed by Hadrian in 119 in consequence of an indiscreet familiarity with the empress Sabina. The remainder of his life was probably devoted to literary pursuits, and from the list of his works given by Suidas he must have been one of the most voluminous of Roman authors. His chief extant work is the *Vita XII Cæsarum*, in 8 books; beside which the treatises *De Illustribus Grammaticis* and *De Claris Rhetoribus*, and some brief biographies of Terence, Horace, Lucan, Juvenal, Persius, and Pliny the Elder, pass under his name. His lives of the Cæsars are anecdotal rather than historical, and their accuracy has been impeached by Heisen, Linguet, and others, although, as would appear from the researches of Krause (*De Suetonii Tranquilli Pontibus et Auctoritate*), without affecting their value in illustrating the period of which they treat. A marked feature of the lives of the Cæsars is the minuteness with which Suetonius relates the gross excesses of the emperors. His personal character, if Pliny may be believed, was above reproach. The works of Suetonius long enjoyed a considerable popularity, 15 editions having been published previous to 1500, of which the oldest with a date is that of Rome (fol., 1470). Among the best subsequent editions are those of Burmann (2 vols. 4to., Amsterdam, 1736) and of Baumgarten-Crusius, by Hase (2 vols. 8vo., Paris, 1828). The first English translation was by Philemon Holland (fol., London, 1606), and the latest by Thomson and Forester (Bohn's "Classical Library," 1855).

SUEUR, LE. See **LE SUEUR.**

SUEVI, the collective name of a powerful group of migratory German tribes, who about the beginning of the Christian era are said by ancient writers to have occupied the larger half of all Germany. Cæsar describes them as dwelling between the Ubii and Sygambri on the W. and the Cherusci on the E.; that is, between

the Rhine and the Weser. According to Strabo, they extended across the central parts of modern Germany, between the Rhine and the Oder, and as far S. as the head waters of the Danube. Tacitus seems to designate by the name Suevi the tribes of eastern Germany from the Danube to the shores of the Baltic. In the 2d century the collective appellation disappears, the single tribes of the group being designated by their distinctive names; later, however, other Suevi, an adventurous German people of mixed origin, appear upon the banks of the Neckar, where they gave rise to the modern name Swabia, and also in northern Spain, where they conquered Galicia in the early part of the 5th century.

SUEZ. I. An isthmus about 75 m. broad, lying between the Mediterranean and Red seas, and connecting the continents of Asia and Africa. With the exception of two small ridges of the respective medium heights of 80 and 45 feet, the surface is only elevated from 5 to 8 feet above the level of the adjoining seas, and has a general depression toward the Mediterranean. In places it is so low as to be covered with salt marshes or swamps, and it is supposed that at one time the two seas were united. There are some considerable lakes, generally dry for most of the year, and the rest of the isthmus is a barren sandy desert, uninhabited. Fresh water is exceedingly scarce, being only found in a few places. A canal, begun by Necho and finished by Darius, connected the Nile with the gulf of Suez, and some traces of it are still visible. Napoleon projected a canal between the Red and Mediterranean seas, and for many years this subject has attracted considerable attention in Europe. In 1852 M. de Lesseps, a French engineer, undertook to form a joint stock company to cut a ship canal, and two years afterward he obtained a firman from the pasha of Egypt conferring upon him the exclusive privilege of carrying out the project. In 1855 a commission of engineers from various countries examined the proposed route, and stated in their report that there were no extraordinary difficulties in the way. The company was formed in Jan. 1859, with a capital of \$40,000,000, and the work was shortly afterward commenced. According to this project the canal is to extend between the town of Suez and the gulf of Pelusium, to be 90 miles long, 20 feet deep at low water level of the Mediterranean, and 380 feet wide on the surface. II. A gulf forming the N. W. arm of the Red sea, extending from its head in a N. W. direction for about 200 m. between Egypt and the peninsula of Sinai, with a breadth varying from 80 to 40 m. The Israelites are supposed to have crossed about 2 m. from the head of this gulf on their exodus from Egypt. III. A town of Egypt, situated near the head of the gulf, 77 m. E. from Cairo; pop. about 2,000. It stands in a desert, and is protected on the 3 sides by a wall mounting a few guns. The streets are unpaved, and the houses gener-

ally poorly built of sun-dried brick. It contains several mosques and khans, a Greek church, a custom house, a large hotel for the accommodation of European travellers, recently erected by the pasha, a bazaar, and some tolerable shops. Good water and vegetable productions are not procurable near the town, and supplies of both have to be brought from considerable distances. Vessels of a large size find safe anchorage in the roadstead about 2 m. off, but there is only sufficient depth of water for boats and lighters to come alongside the quay. Suez is connected with Alexandria by a railway 222 m. long, which passes Cairo, and crosses the Nile by a magnificent bridge 65 m. from Alexandria. The place derives its importance from being a port of the overland route between England and India, China, and Australia.

SUFFOCATION. See ASPHYXIA.

SUFFOLK. I. An E. co. of Massachusetts, bounded E. and S. by Massachusetts bay; area, 15 sq. m.; pop. in 1860, 192,701. It is composed of Boston and Chelsea, and is the most important county in wealth and population in New England. Its inhabitants are principally engaged in manufacturing and trading. The agricultural productions in 1855 were 3,160 bushels of rye, 8,256 of Indian corn, 9,010 of potatoes, and 1,089 tons of hay. (See BOSTON, and CHELSEA.) The county is intersected by numerous railroads. Capital, Boston. II. An E. co. of New York, comprising the E. part of Long island, bounded N. by Long Island sound, and E. and S. by the Atlantic, and drained by the Peconic river and several smaller streams; area, 950 sq. m.; pop. in 1860, 43,276. The surface is hilly and uneven on the N., but nearly level on the S.; the soil is generally sandy, but fertile along the sound. The productions in 1855 were 504,787 bushels of Indian corn, 151,649 of wheat, 262,067 of oats, 804,068 of potatoes, 104,188 of turnips, 634,405 lbs. of butter, and 41,505 tons of hay. There were 8 straw paper mills, 25 ship yards, 3 spar factories, 1 cotton and 2 cotton warp factories, 2 clock factories, 1 piano factory, 5 newspaper offices, 112 churches, and 146 schools. The coast is indented by numerous harbors and inlets, and the county includes several small islands. It is intersected by the Long Island railroad. Capital, Riverhead.

SUFFOLK, a county of England, bounded by Norfolk, Cambridge, Essex, and the North sea; area, 1,481 sq. m.; pop. in 1861, 336,271. It contains two county towns, Ipswich and Bury St. Edmunds; other chief towns, Eye, Aldborough, Orford, and Sudbury. The coast line extends about 50 m., and a great part of it is low and marshy. The county is watered by numerous streams, the chief of which are the Stour, Orwell, Lark, and Waveney; and there are several small lakes. The surface is undulating, with some flat and marshy tracts, and the soil is generally a rich alluvial loam. The manufactures, with the exception of agricultural implements, are trifling. Fishing is

actively carried on upon the coast. There are many remains of antiquity, including the Roman castle of Burgh, the walls of which are still standing. Suffolk returns 9 members to parliament, 4 for the county and 5 for the boroughs.

SUFISM. See SOOFERISM.

SUGAR (Arab. and Per. *sukkar*; Lat. *saccharum*), a sweet substance obtained from the juices of many plants, and in some of its varieties from animal fluids also. It constitutes an important article of food in very general use throughout the world, and is the chief source of nutriment in fruits, appearing in them as they ripen. Important as sugar is now regarded by the great proportion of the human race, it does not appear to have been generally known to the nations of antiquity, except to the inhabitants of China and India. The sweet calamus and sweet cane, of which mention is occasionally made in the Old Testament, were most probably the sugar cane, which may have been introduced from eastern Asia. But it must have slowly come into use; for the ancient classical authors, Strabo, Theophrastus, Arrian, and others, who allude to it, speak of it as a kind of honey obtained from a reed growing in India and Arabia; while Dioscorides and Pliny describe it as resembling salt, and only used in medicine. This substance, termed *sakkapor*, is, however, in Smith's "Dictionary of Greek and Roman Antiquities" (art. "Saccharum"), described as "a natural concretion, forming on certain reeds, but more especially on the bamboo cane;" and it is added: "It would appear that Moses Chorenensis, in the 5th century, is the first author who distinctly mentions our sugar, that is to say, the sugar procured by boiling from the sugar cane." This does not conflict with the older allusions to sugar cane and its sweet juice, which it is evident was long previously eaten with avidity, as the Zooloo Caffres at the present time eat the Chinese sugar cane. (See *Sorghum*.) Yet Eratosthenes speaks of roots in India sweet to the taste even when boiled, in such manner that many have supposed he referred to sugar extracted from the cane. Others again agree with Dr. Moseley, who thinks the remarks of Pliny and Dioscorides applicable to the sugar candy which the Chinese are known to have made from ancient times, and which may very likely have found its way in small quantities even to Rome. Sugar canes were found in abundance near Tripoli in Syria by the crusaders; and Albert Aquensis, a monkish author of that period, speaks of the plant being cultivated with great care, and when ripe of the juice being beaten out in mortars, strained, and set aside till it concreted in a snowy or salt-like product. This was eaten with bread or with water, and was found more agreeable than honey. The Saracens introduced sugar canes into Rhodes, Cyprus, Crete, and Sicily, when they obtained possession of those islands in the 9th century. They also were acquainted with

the method of making sugar, and the manufacture was soon permanently established in the countries of the Levant. From these sugar was carried to Venice as early as 996; and in the 12th century it was imported there more cheaply from Egypt than from Sicily. William, king of Sicily, in 1166 gave a mill for grinding sugar canes to the monastery of St. Benedict. The first sugar cane cultivated in Spain was in Valencia, introduced there by the Moors after their conquest of the country; the culture thence spread to Granada and Murcia. In the early part of the 15th century the plant was introduced into Madeira and the Canary islands, and from the latter it is supposed that the first plants were taken to Brazil; but it is not at all improbable that the sugar cane was a natural product of America; and it may be that it is only for the process of making sugar from it that the new world is indebted to the Portuguese and Spaniards. The first cultivation of the sugar cane in the West Indies was at the island of St. Domingo or Hayti, where it was successfully prosecuted at the time of the second expedition of Columbus, 1498 to 1495; and in 1518 there were 38 works for making sugar in operation. The soil and climate proved admirably well suited for the crop; and for a long time this island furnished the chief portions of the European supplies of sugar. Previous to the revolution, near the close of the last century, the export of sugar had amounted to 69,000 tons a year. The English began to export sugar from Barbados in 1646, and the trade soon gave employment to a large number of ships. The Portuguese also at the same period were sending large quantities of sugar to European countries from Brazil; and toward the close of the 17th century the culture had been generally established throughout the West India islands, in Mexico, all of Central America, the northern countries of South America, Peru, Chili, &c. Mention is made of the sugar cane among the indigenous productions of Virginia and North Carolina by the earliest settlers of the banks of the James and Neuse rivers; but it seems probable they must have mistaken for it the common reed. The plant appears to have been cultivated on the banks of the Mississippi for the first time about the year 1751, when some Jesuits brought it from St. Domingo, and settled just above the site of New Orleans. In 1758 the first sugar mill was built a little further down the river by M. Dubreuil on his sugar plantation. The culture according to some accounts prospered, so that in 1770 sugar was one of the staple products of the colony, and after the revolutionary war it was prosecuted so successfully by emigrants from the United States, that there were in 1808 as many as 81 sugar estates on the delta alone. But according to the statement of E. J. Forstall in De Bow's "Industrial Resources," vol. iii. p. 275, "the manufacture of cane into sugar does not appear to have commenced before 1764, when samples were sent to the mother country from the es-

tate of Chevalier de Mazan, near the city (New Orleans) on the opposite bank. The cession of Louisiana to Spain at that epoch appears to have put a stop to that industry, for no further traces of sugar making are to be found until 1791, when the first sugar house under the Spanish government was erected by a Mr. Solis at Terre aux Boeufs in the parish of St. Bernard. The next was established in 1796 on a plantation where now stands Carrollton." The successful result of this operation laid the foundation of the sugar industry of Louisiana; which still, however, advanced very slowly, and at the time of the cession of Louisiana to the United States (1808) the number of sugar estates was very small. In 1818 the crop amounted to 25,000 hogsheads, and the cane was ground altogether by cattle. Steam power was introduced in 1822. The further progress of the culture is presented in the tabular statements at the close of this article. The sugar-growing district in this state is on both sides the Mississippi river, from 57 m. below New Orleans to nearly 190 m. above; on Red river, including Rapides and Avoyelles; on many of the bayous and their tributaries; the prairies of St. Martin, Vermillion, &c. In Texas the crop has lately become an important one; and it is increasing in all the gulf states. It is even cultivated to some extent, as will be seen in the tables referred to, in South Carolina, Tennessee, and Kentucky. Yet the climate of Louisiana itself is rather north of that best suited to the plant, the cane being frequently killed by the frost after starting in the spring, and at maturity in the latter part of October and in November, the effect of which is to materially diminish its production of sugar. In 1857 injurious frosts thus occurred in April as late as the 22d, and on the 19th and 20th of November. In November, 1859, the cold was very severe on the 12th, 13th, 14th, and 15th in all parts of Louisiana, the thermometer on the 14th standing at 25° F. at New Orleans, and thick ice being formed in the most southern parishes. The effect of this was that the cane was everywhere frozen, and land which had previously given above 2 hogsheads to the acre yielded barely half a hogshead, and this of inferior quality. The climate is also subject to long continued droughts which seriously injure the growing crops. From some other cause not well understood the product of sugar to the acre is not so great as it has been in past years. This may be owing to continued repetition of the same crop without adding manures to the land, or to the practice of reserving inferior canes for seed, while some have supposed it is caused by deterioration of the stock through continued use of cuttings from the same source. To remedy the trouble, in case of this being the cause of the deterioration, the United States government recently collected a new supply of canes from the northern parts of South America and distributed them among the planters. The sugar plantations are also often seriously

damaged by the Mississippi river bursting through crevices in the banks and flooding the low country.—The sugar cane is said to be a natural product of some of the islands of the Pacific; and it certainly flourishes with great luxuriance in many of the tropical countries and islands of Asia. But though the chief, it is not the only source of the cane or crystallized variety of sugar either in the old or new world. This is also obtained from the beet root and the juice of the sugar maple tree, and of several trees of the palm tribe. Sugar was discovered in the parsnip, the white and red beet, carrot, and juice of the birch in 1747, by M. Margraaf, of the royal academy of sciences in Berlin; and in 1796 M. Achard analyzed the beet root in Berlin, and obtained from it 5 per cent. of white sugar and 8 of molasses. The high price of cane sugar rendered the discovery of some new source of it a matter of great importance, and a factory was established at Oumoom in Silesia for extracting it from the beet root. When in the time of Napoleon I. colonial products were excluded from France, this manufacture assumed still greater importance; and a great impulse was given to it by the offer of a premium of 1,000,000 francs for the best method of producing sugar from native products. The highest chemical talent of France was directed to this object, and the resulting discoveries and improvements were afterward applied with great advantage to the treatment of the sugar cane. The readmission of West India sugars on the return of peace nearly broke up the beet root manufacture, and this was only kept alive by the imposition of high duties on foreign sugars in 1820 and 1822. From that time the product rapidly increased, amounting in 1838 to over 86,000,000 lbs., or about 42,000 tons, in 1857-'8 to 150,000 tons, and in 1858-'9 to 180,000 tons. In Germany, Belgium, and Russia, beet sugar is also produced to a considerable amount. In 1858-'9, 36,668,557 cwt. of roots were consumed in 250 sugar refineries in the Zollverein. As 12½ cwt. of roots are considered equal to 1 cwt. of sugar, this should represent 146,674 tons of sugar. In the Austrian empire there were consumed 16,042,248 cwt. of beet roots. In Belgium the same year the product of beet sugar was 18,000 tons. The manufacture in these countries is encouraged by a protective duty. Russia is said to produce from 80,000 to 40,000 tons of beet sugar annually. The annual product of maple sugar in the United States has been estimated at about 27,000 tons. The manufacture is carried on in Pennsylvania, Ohio, New York, Michigan, the New England states, and also in the British provinces. A much larger quantity of sugar is obtained from the wild date and the gomuti palms than from the maple, the product being rated as ¼ of all the cane sugar manufactured. In India the process of extracting the sugar is very rude, causing much of it to assume the uncrystallizable condition. The crude, dark brown, deliquescent sugar, called in India

jaggery, is the product of the evaporation of the toddy or palm juice. Beside these sources, cane sugar may also be obtained from the pumpkin, the chestnut, the young shoots of the Indian corn, and a large number of tropical fruits. The character of the Chinese sugar cane as a sugar-producing plant has been considered in the article *Sorghum*; and the evidence at hand to the end of the year 1861 was unfavorable to the prospect of its yielding in this country crystallizable sugar to profit. But reports from Ohio published in Jan. 1862, give more favorable accounts of the success of the trials of the preceding year, and make mention of the exhibition of a number of fine samples of the sugar at a convention in Columbus, Ohio, on Jan. 7; and we learn that in the north-western states it is already a common article of commerce.—The sugars may be included in 4 principal varieties, of which that termed cane sugar, also called sucrose, is the most important, and is the common commercial variety. The second, called fruit sugar or fructose, exists in honey, treacle, and most acidulous fruits. It is a sirupy liquid, not crystallizable, though by boiling with dilute acids it may be partially converted into the next variety, which is crystallizable. The third sort is called grape sugar, starch sugar, or glucose. It exists in the juice of many plants, and constitutes the crystals which form in honey, and also the hard, granular, sweet masses common in old dried fruits, as raisins, figs, &c. It is also produced by boiling, with dilute acids, starch, cane sugar, ligneous fibre (as linen rags), sugar of milk, &c.; and is occasionally met with as a morbid constituent of the urine in cases of diabetes. It crystallizes in cubes or square tables, and from hot alcohol in anhydrous prisms. Its sweetening effect compared with that of cane sugar is about as 1 to 24. Glucose is manufactured to a considerable extent at the starch factories in Europe from potato starch, or rather dextrine, and is made use of in the manufacture of beer and an inferior sort of alcohol, designed for conversion into French brandy by the addition of certain essential oils or flavorings. It is produced by the action of diastase upon the dextrine in the preliminary stages of malting and mashing, but is more expeditiously made by treating the starch with sulphuric acid. It differs from starch ($C_6H_{10}O_5$) only by containing in addition the elements of 2 more equivalents of water, and also 2 equivalents of water of crystallization, with which it parts when carefully dried, becoming then $C_6H_{12}O_6$. Melting in its water of crystallization at $212^\circ F.$, this sometimes serves to detect its presence in cane sugar. It differs from this also in being much less soluble in water, and in forming definite compounds with alkaline and earthy bases, which decompose and become brown at temperatures from 160° to 212° . Other points of difference will be noticed below. The fourth variety, called milk sugar, sugar of milk, lactine, or lactose, occurs only

in the milk of animals, and is inferior to the last described in sweetness. These substances all consist of carbon, hydrogen, and oxygen, the two latter elements always existing in the exact proportions required to produce water; for which reason, although these elements are not regarded as so combined, the compounds are sometimes spoken of as hydrates of carbon. While the highest grade of sugar, the cane variety, is readily converted into the inferior grape sugar, all attempts to reverse the process, which would be a discovery of immense value, have entirely failed. The comparative composition of the sugars as respects the proportion of water they contain is presented in the following table, which is based upon quantities of each containing 12 equivalents of carbon:

Sugars.	Carbon.	Water.
Cane sugar, $C_{12}H_{22}O_{11}$	72	99
Fruit sugar, $C_{12}H_{22}O_{12}$	72	108
Grape sugar, $C_{12}H_{22}O_{12} \cdot 2H_2O$	72	126
Milk sugar, $C_{12}H_{24}O_{12}$	72	108
Ditto, dried, $C_{12}H_{18}O_{10}$	72	85.5

—Cane sugar, as first obtained on evaporating the saccharine juices, is a yellowish brown substance in coarse crystalline powder and lumps, more or less moist and sticky, and containing variable quantities of glucose, treacle, and several organic and mineral substances. Lime is one of the latter, and it is thought that its presence induces the change in crude sugars, which after a time become gummy and soft and lose a portion of their sweetness. The foreign organic matters present impart to the crude sugars their peculiar taste and smell, and betray their particular source. These disappear when the sugar is refined. The best brown sugar has little odor and is in large sparkling grains. When refined, the sugar is converted into a hard and brittle crystalline mass, and is often moulded into conical loaves. Its specific gravity is then 1.606, giving 1,606 ounces avoirdupois to the cubic foot. In the large crystals, known as sugar candy, obtained by evaporating a saturated aqueous solution, prepared at a temperature of 212° , the sugar is colorless; but in the crystalline grains it is of snowy whiteness owing to the numerous reflections and refractions from the crystalline faces. The form of the large crystals is that of rhomboidal prisms terminated by dihedral summits. If the solution be prepared at 280° , or be long boiled, the sugar forms an amorphous mass on cooling. Pieces of loaf sugar rubbed together emit a pale violet phosphorescent light. Sugar is soluble in about $\frac{1}{4}$ of its weight of cold water, and in all proportions in boiling water. It is sparingly dissolved in boiling absolute alcohol, but deposited again when cold. At the temperature of 320° it fuses, and on cooling forms the amber-colored solid known as barley sugar. When the temperature is gradually raised to 400° or 420° , sugar loses two equivalents of water, and is converted into the dark brown substance called caramel, used for coloring wines. At a still higher temperature decom-

position ensues, and a residue is left of very porous shining charcoal, about $\frac{1}{2}$ the weight of the original substance. Under the influence of yeast vinous fermentation takes place in solutions of sugar, by which this is first converted into fruit sugar, and then into carbonic acid and alcohol. Cane sugar is rapidly decomposed and charred by concentrated sulphuric acid. These properties serve to distinguish cane sugar from the other varieties. The solutions of the different sugars also present characteristic effects on polarized light, thus furnishing a very certain means of distinguishing the varieties. The method of thus testing them by the aid of an instrument invented by M. Soleil is described in the *Annales de chimie*, [iii.] xvi. 175. The plane of polarization is rotated from left to right by cane sugar, rather more powerfully than by grape sugar, while fruit or uncrystallizable sugar produces a rotation from right to left. A fresh solution of grape sugar possesses a rotary power double that which it retains after some hours, or after it has been heated to 180° or more and allowed to cool. Its rotary power is not then affected if the solution is heated with an acid; but that of cane sugar is reversed when its solution is heated with $\frac{1}{10}$ its bulk of pure hydrochloric acid, and the temperature is raised for 10 minutes to 154° F.—In the preparation of sugar, a thick, dark brown or black, ropy liquid is drained off from the crystalline portion, which consists of the uncrystallizable sirup together with some cane sugar, and the impurities that may be present. It is called molasses, and is very extensively consumed as an article of diet, and also in connection with the skimmings of the sugar kettles for the production of rum. (See MOLASSES, and RUM.) A better article, called sugar house molasses, and sometimes treacle, of specific gravity about 1.4, is obtained in the process of refining brown sugars. The article called *melado* lately introduced in commerce is a low grade of sugar heavy with molasses, obtained from the settlings of the cisterns in which the molasses is collected, and from partial boiling down in vacuum pans without refining.—Sugar is employed in a great variety of ways as a nutriment and condiment; but though nutritious and promoting the formation of fat and lactic acid, providing material for the maintenance of respiration, and promoting by its oxidation heat in the system, it cannot through its deficiency of nitrogen alone support life. It is the basis of the various preparations known as confectionery; and it is a valuable material for preserving fruits, meat, and fish, and is largely used especially for the saccharine confections known as preserves and sweetmeats, and in curing hams. (See PRESERVATION OF FOOD.) It is a prevailing opinion that sugar is injurious to the teeth; but it is found to have no action upon them out of the body, and if it affects them in the system it is probably by its first disordering the digestive organs, when taken in excessive quantities. Molasses has an aperient

action, and sugar has the same also in less degree; but their more important medicinal property is that of a demulcent, for which they are much used in catarrhal affections. In pharmacy sugar is employed for a variety of purposes, especially as a medium for administering many active medicines and disguising their disagreeable taste, or preserving them from change. It forms the bulk of most of the sirups and confections, and of all the troches or lozenges. Molasses is useful in the preparation of many pills, keeping them soft and moist, while at the same time preventing mouldiness or other change. Sugars are rarely adulterated to any injurious extent, and there are few substances that could be added to the white sugars and not be readily detected by their insolubility in water, their leaving an ash when consumed, or their imparting a peculiar taste to the mixture. Starch and starch sugar have been used for this purpose. The brown sugars met with in the London market are so impure, in consequence chiefly of the defective methods employed in their manufacture, that they have been pronounced by Dr. Hassall in general unfit for human consumption. The exceptions are some large-grained, clear, dry, crystalline sugars, evidently made from juice purified by filtration before boiling. The brown sugars almost universally contain minute fragments of cane, sporules and filaments of fungus, grape sugar, molasses, and great numbers of the sugar mite (*acarus sacchari*), a disgusting insect large enough to be seen by the naked eye. When a quantity of sugar containing them is dissolved in a wine glass of tepid water, and left at rest an hour or so, the animalcules are seen on the sides of the glass, upon the surface of the mixture, and in the sediment at the bottom. In England it is the custom with the grocers to "handle" the sugars, which means mixing sugars of different qualities, and thus disguising the worst sorts. The purest large-grained brown sugars are scarcely sold at retail, and their introduction is discouraged by the grocers, because, as stated by Dr. Scoffern, they are incorporated with difficulty among the inferior sugars, and betray to the eye the mixing practice.—*Manufacture*. This may be regarded as commencing with the cultivation of the cane. This plant (*arundo saccharifera*) belongs to the natural order of *gramineae* or grasses. It grows in a succession of joints, or rather nodes, from 4 to 20 feet high, and the stem is 1 to 2 inches in diameter. Long slender leaves shoot forth from the opposite sides of alternate joints, and fall off when the plant comes to maturity. From the top there appears, when the plant is 11 or 12 months old, a sprout called the arrow, which grows to the length of 7 or 8 feet without joints, terminating in an ample panicle about 2 feet long with numerous white flowers. Seeds are rarely produced by the cultivated canes, and it is stated that the plant is nowhere raised from these, but always from the cuttings of the stalks. The

stem is smooth and straight, the joints 3 to 6 inches apart, and the outer coating hard and silicious, and when ripe of various shades of yellowish, violet, greenish, and red. Between the joints the cane is filled with a whitish spongy tissue, which under the magnifying glass is seen to consist of numberless cells containing the saccharine juice. The principal varieties of the cane are the creole, also known as the crystalline, and Malabar; the Otaheite, and the ribbon or Batavian. The first, which was formerly cultivated in Louisiana as the most valuable variety, has there run out, and has given place to hardy varieties of the ribbon cane from Java, which have also greatly deteriorated, as affirmed, through an injudicious system of culture. The creole and Otaheite are cultivated in the West Indies and in South America. The latter variety is highly esteemed, and in Jamaica it is said to grow the first year 12 to 14 feet high, with stems 6 inches in circumference, and joints 6 inches apart. In the East Indies a number of other varieties of cane are cultivated, among the most productive of which is the Salangore cane, grown in the straits of Singapore, which have produced at the rate of 7,200 lbs. of undrained sugar to the acre, equal to 5,800 lbs. of dry sugar for shipping. The method of planting varies in different countries; but in general the practice is, after breaking up the land, to run straight parallel furrows through the plantation at distances 4 to 6 feet apart in the West Indies, or 8 feet in Louisiana, in which furrows slips of the cane, each having several joints, are placed, 2 to 5 feet apart, and lightly covered. In Louisiana some planters lay 2 to 4 canes in each furrow, lapping the same the whole length. The spaces between the rows are kept well ploughed or hoed. In the West Indies the best season for planting is from August to November; the cutting may be in March and April, but is often performed at any convenient time during the year. In the southern states, where the ground is liable to be frozen, the plants are usually put in between January and March, and the crop is gathered in October. The slips for seed are then selected, and, though it would be true economy to reserve the best canes for this purpose, the planters are generally unwilling to do it, and hence one cause of the deterioration alluded to above. Were the planting done every year, this would be a much more serious consideration than it is at present, the canes growing upon an acre being not more than enough to plant 4 or 5 acres; but after the removal of the canes new shoots spring up from the stubble, and these, known as ratoons, though not as large and vigorous as the "plant canes," afford better juice, which is more readily converted into sugar. In Louisiana a succession of only 8 crops can be depended on from one planting; while in the West Indies the ratoons continue to renew themselves sometimes for more than 20 crops. About $\frac{1}{2}$ of the product therefore, it is seen, must be reserved in Loui-

siana for seed. The yield of sugar in the southern states is from 500 to 2,000 lbs. to the acre; in the West Indies 3,000 to 5,000 lbs.; and in the East Indies the highest product is about 7,000 lbs. In Mauritius the product is said to have been increased from 2,000 or 2,500 lbs. to the acre to 6,000 and 7,000 lbs., and in some cases even more than this. At maturity the canes are cut off close to the ground, and are stripped of the tops and leaves, which, under the name of trash, are left upon the ground, to protect, in this country, the roots from frost during the winter. The practice is to consume this sooner or later by fire, though some of the southern planters strongly recommend its being ploughed under in the spaces between the rows. The canes contain most sugar in the lower third of their length; the juice in the tops is watery and not worth saving. Cattle, horses, and mules are fond of all parts of the plant, and the tops and leaves when fresh make for them good fodder. As soon as the canes are cut they should be taken to the mill and ground, as they are liable to soon ferment in the warm climate, and thus lose a portion of their sugar. They are found to contain when analyzed from 66 to 78 per cent. of water, 12 to 21 per cent. of sugar with a very small quantity of other soluble substances, and 9 to 17 per cent. of ligneous fibre. But owing to the imperfections of the manufacture, it is supposed that not $\frac{1}{4}$ of the sugar in the cane is saved, the product not really exceeding that obtained by the French manufacturers from the beet root, which contains an average of only about 11 per cent. of sugar. The mills employed for crushing the canes are of a great variety, and those in use from ancient times in the East Indies are exceedingly rude, and slow and inefficient in their action, worked by oxen. Mills not much better are still employed by small planters in the West Indies; but powerful machines driven by steam are in operation upon the more important sugar estates, the crushing apparatus consisting of 8 heavy cast iron rollers, between which the canes are passed. They revolve horizontally, one called the top roller over the two others, one of which is the fluted feed roller and the other the delivering roller. The canes are spread upon a cast iron feed plate sloping down to the upper edge of the feed roller, and are drawn into the space, usually of about $\frac{1}{4}$ an inch, between this and the top roller, and are discharged through the space of about $\frac{1}{4}$ of an inch between the top roller and the delivering roller. Very efficient machines are also in use with 2 rollers above and 2 below. After passing once through, the crushed canes, now called bagasse, or in English works megass, are returned to the feed plate either by hand or by the mechanical contrivance called the dumb returner, and are again compressed. About $\frac{1}{4}$ of the whole juice is thus extracted, and runs down into the troughs or receptacles placed beneath to collect it. The remainder is obstinately held by

the bagasse, and no effectual means of recovering it has yet been devised. A method which has been favorably spoken of, some time since patented in England by Mr. Michiel, and called the maceration process, entirely dispenses with the mill. It consists in cutting the canes into extremely thin slices with circular knives, and then submitting them to the action of a mixture of lime and water. The lime is supposed to coagulate and render insoluble all the nitrogenous matters, and the whole of the sugar to be taken up by the water. On an estate in the island of Martinique the adoption of this process is reported to have increased the yield of the cane from 5 or 6 per cent, which it previously was, to 11 or 12 per cent. The difficulties attending its use are the rapid wear upon the knives and the time and labor required in their use over that in grinding. The bagasse, consisting largely of carbonaceous matters, burns freely, and is advantageously used as fuel in the boiling operation. The following are results of some of the analyses of its ash made by Dr. Stenhouse; Nos. 1 and 2, of cane of Trinidad; No. 3, of cane of Berbice; and No. 4, of cane of Demerara:

Constituents.	1.	2.	3.	4.

The capacity of the mills should be about 100 gallons of juice an hour for each horse power. The crude liquor contains various impurities, as particles of woody fibre, coloring matter, different soluble salts, albumen, caseine, wax, &c. The nitrogenous substances induce immediate fermentation and the conversion of a portion of the sirup into alcohol and afterward into acetic acid, thus not only reducing the product of sugar, but introducing new compounds, which might prove detrimental by acting upon the lead and copper of the apparatus and adding their poisonous salts to the sugar. Not much time should therefore be allowed for a portion of the impurities to settle before the liquor is drawn through the strainers of copper or iron wire into the vessels for clarifying it. By the old method practised in Asia a series of 11 kettles or earthen boilers is set in a line in a rudely constructed boiler range, at one end of which is the fire, with a large iron boiler placed over it, and at the other the chimney. The juice is first put in the boiler furthest from the fire, and is gradually transferred to the others, as the process goes on, until the final concentration is effected in the iron boiler. The product is afterward drained and the sugar is clarified by boiling again with water, an alkaline lye, and milk.

VOL. XV.—11

A somewhat similar arrangement of kettles, to the number of 4, 5, or 6, has also been employed in this country and the West Indies, each kettle, however, having its own fire, and the defecation or partial purifying being effected during the boiling by "tempering" the liquor with slaked lime. This, when used in small quantity, causes the glutinous matters present to coagulate and rise upon the surface in a scum, which may be continually removed by skimming. It also neutralizes any acid that may have formed. In Louisiana it has been the practice to concentrate the sirup to 42° Baumé in the last kettle, called the battery, and then transfer it to large wooden vats, called coolers, for granulation; but the operations have been variously modified there, and different methods too have been pursued in the West Indies. Instead of kettles, each one requiring a separate fire, large copper caldrons or "teaches" are used, into which the juice is conducted from the strainers in troughs lined with lead; and these caldrons are heated by steam either by being enclosed in a steam jacket or by containing a coil of steam pipe. The clarification is effected as before by means of lime added to the sirup diffused through a portion of juice, or in the form of milk of lime of known strength and carefully graduated, so that exact quantities may be used. Just enough should be used to neutralize exactly the sirup, which may be known when litmus paper indicates neither an acid nor alkaline reaction. An excess of lime should be particularly guarded against, as it involves a loss of sugar; and when it occurs the effect should be corrected by careful addition of alum, or better of sulphate of alumina, which contains no potash. The heat employed in clarifying should not reach the boiling point of the sirup. At a less degree a scum gathers upon the surface, and when this rises in large bubbles and breaks up into white froth, the clarification is completed. The heat is then stopped, and the liquor is left to repose for an hour, when it is drawn away from the scum, and is seen as it flows into the first of the evaporating pans to be of a clear bright wine yellow color. These pans, to the number of 8 or more, are set in succession over a flue heated by a fire at one end. The liquor is gradually transferred to the smaller pans, and as it boils away the scum that rises is taken off. It is the skimmings in these operations that furnish the best materials for distillation, and the manufacture of rum is very generally carried on in connection with that of sugar. In the smallest and last pan, to which sometimes the term "teache" is exclusively applied, the sirup is finally collected; and when it is judged to be sufficiently concentrated for granulating, it is transferred, or as it is called "skipped," into the coolers, and thence into the vessels, also called coolers, in which the granulating takes place. These are of wood with thick sides, about 7 feet in length, 5 or 6 in width, and not less than a foot deep. This

depth and the thick sides are requisite to secure slow cooling, without which the grains could not be coarse. In about 24 hours the graining takes place, the crystals forming a soft mass in the midst of the liquid portion or molasses. The separation of the two products is effected by drainage in what is called the curing house. This is a large building covering an open reservoir in the centre. Frames are provided for hogsheads so that the drippings from these shall flow into the reservoir. In the bottom of each hogshead several holes are bored, and into each hole is put a crushed cane or the stalk of a plantain leaf, the lower end projecting several inches below the bottom. The hogsheads being filled with the soft sugary mixture, the molasses gradually drains away from it, dripping from the stalks. The operation goes on for 3 to 6 weeks, till the sugar is considered sufficiently dry for shipping. It still, however, retains considerable molasses, and in the moist hold of the ship the separation continues to take place, the molasses leaking away and involving a serious loss. Of the sugars formerly shipped from St. Domingo to France the proportion thus wasted was estimated at $\frac{1}{3}$. It is this variety of sugar that is known in commerce as muscovado.—Various improvements have been introduced in the manufacture as described, most of which originated with the French chemists, in their attempts to perfect the beet sugar manufacture. Such are the methods of filtering the juice after it leaves the clarifiers, either by means of fine copper wire sieves, of flannel bag filters, or of the cylinders filled with coarsely pulverized bone black or animal charcoal, invented by Dumont. The object of this last is to remove the coloring matter from the juice, and all mineral salts that may have been in it originally, or any excess of lime. The bone black is used in a large iron or copper vessel 6 to 12 feet high, furnished with a perforated bottom, which is covered with a filtering cloth, upon which is placed the charcoal. Five tons of this suffice for 100 tons of sugar; after which the charcoal itself requires to be purified, which, after the sugar it retains has been washed out, is usually effected by recalcination. An ingenious and economical mode has been devised where steam heat is used of concentrating the juice from the filters before evaporating. The pipes conveying the waste steam are arranged in a rack or coil, like the hot air pipes for warming rooms, and the juice is made to trickle over these, the effect of which is that it is greatly concentrated by evaporation before it flows away in the pipe in which it is collected at the bottom of the apparatus. The steam in the pipes is condensed by loss of latent heat, and the lower pipes are so much cooled that no danger is incurred of their burning the sirup, which in its denser condition is more liable to be thus injured. Where this expedient is adopted, the vacuum pan is employed for evaporating, and it is the waste steam from this that is made use of.

This very important apparatus was invented by Howard in England in 1812, and has been applied rather in the subsequent refining of sugars than in the preparation of the crude article. Its object is to facilitate evaporation and render it practicable at so low temperatures that all risk of burning the vegetable juices, or medicinal extracts when used in the preparation of these, may be avoided. As used in the sugar manufacture, it is a large flattened spheroidal vessel of copper, sometimes 8 feet in diameter, made in 2 parts, a pan beneath surmounted with a dome-shaped cover, secured together by bolts through their flanges. The pan is surrounded with a cast iron steam jacket, and a coil of steam pipe is laid round it inside, by which heat is supplied for boiling the juice. The steam produced in the vacuum pan by the evaporation of the juice is taken off by the condensing apparatus described above, or where this one is not required, then by a special condenser. The effect of either is to produce a partial vacuum in the pan, diminishing the pressure upon the surface of the liquid and facilitating its evaporation. An air pump is also provided for the purpose of exhausting when necessary the air in the machine and the water that condenses in the pipes. The large pans are furnished with various appendages, as an overflow side vessel connected with the dome by a large pipe, and serving to catch any sirup that boils over; a man-hole cover of gun metal at the top; a thermometer for indicating the temperature of the sirup; a barometer for marking the pressure within; a measure with pipes and cocks holding about 85 gallons, into which the juice is first passed before it is admitted into the pan; a piston so arranged with a proof stick that a sample of the contents may be extracted for examination without letting air into the pan; a similar contrivance by which a piece of butter may be introduced for the purpose of checking too violent boiling; an apparatus in the bottom for letting out the sugar as desired; glasses inserted in the dome, one on each side, for observation of the condition of the contents; beside the various apparatus connected with the supply of steam and regulation of its pressure. In using the machine, enough of the sirup is run in to cover the heating surface of the pan; the steam is then turned on, and the heat kept at 180° to 190° F. till granulation begins to take place; it is then lowered to 160° and finally to 145° , which is the lowest point at which proof sugar boils at 8 inches below a perfect vacuum, or at a pressure equivalent to 27 inches of mercury, 80 inches marking a perfect vacuum. When the first measure is sufficiently granulated, the sugar is not withdrawn, but another similar charge of sirup is added, and so the operation is renewed to the full capacity of the pan. This method has the effect of giving increased coarseness to the crystals, which more readily form upon those already produced. The sirup filled with crystalline sugar is finally let down into a large

copper pan beneath it, called the heater, in which the temperature is raised to 180°, while the sirup is stirred with paddles to promote granulation. The sugar is then transferred into conical-shaped moulds, in the small end of which is a hole temporarily plugged; and these are left several hours for the sugar to solidify. The plugs are then removed, and the moulds of sheet iron or unglazed earthenware are kept at a temperature of about 100°, while the uncrystallized sirup drains through into vessels placed to collect it. While in this state, the operation called claying is performed, a practice very generally followed in the West India islands. A layer of whitish clay thoroughly mixed with water is laid upon the surface of the sugar, and left until the water has passed down into the sugar. As it goes through, it carries the remaining sirup along with it; and when the clay is left dry this is renewed by a fresh layer. The method termed "liquoring," which is pouring a saturated saccharine solution upon the sugar, is practised in the sugar refineries, and will be noticed in treating of them. The drainings from the moulds are reboiled with raw sugar or with the refuse of the sugar house to produce inferior sorts of sugar. The sugar when taken from the moulds is in solid loaves, more or less white according to the manner in which the process has been conducted. Discolored portions on the exterior are removed by dressing the loaves, after which they are finally dried at a temperature of 130° to 140°. Sugar equal to the best refined might thus be obtained direct from the canes by the same process as that in use for refining the impure sorts. The use of the improved machinery has already resulted in largely diminishing the waste and improving the quality of a considerable portion of the sugars shipped from the West Indies, South America, &c.—*Sugar Refining.* The preparation of the purest varieties of sugar did not originate in the sugar-producing countries, but the art was applied first by the Venetians to the crude sugars brought from Egypt. It was practised in Antwerp in the 16th century, and was thence introduced into England. At present it is an important branch of manufacture in most of the principal commercial cities of the United States and of Europe, and will doubtless long continue to be so, as the various processes connected with it are carried on to better advantage in manufacturing communities than in districts of a purely agricultural character. As formerly practised, raw sugar was dissolved with lime water in a large open boiler, and, when warm, bullock's blood was added, which as it coagulated on boiling collected most of the lighter impurities and carried them up to the surface in the form of a thick scum. This being removed, the liquor was partially evaporated by boiling, filtered through woollen cloth, then concentrated and grained on the general plan already described. The present operations are conducted in large buildings 6 or 7

stories high, which afford facilities for letting the product down from one to another in the different stages of the operation. The raw sugar, in the first place, is discharged upon the open floor, and the hogsheads and boxes are cleared of the sugar which adheres to them by placing them inverted over a steam pipe and directing a jet of steam over the inside. The dissolved sugar flows down into the dissolving pan in which the whole is collected. The pan is sometimes called a blow-up cistern, from the practice of blowing in steam to hasten the solution. This is also effected by hot water and the use of an agitator kept in action by the steam engine. The liquid is raised to the temperature of 165° F., and its strength is brought to about 29° Baumé. If acid, the solution is rendered neutral by adding lime. Some manufacturers introduce blood at this stage, and after the addition the solution is boiled. In case the raw sugar was not at first hoisted to the upper floor of the building, the liquor is now raised to it by pumping, where it is first filtered through long bags of twilled cotton, strengthened by outer ones of strong linen. The liquor runs away from them resembling in color dark sherry wine. The color is removed by passing the solution through filtering beds of granulated animal charcoal (see BONE BLACK), which, in pieces as large as peas, is contained in cylinders of cast or wrought iron of 5 to 10 feet diameter and from 10 to 50 feet high. The quantity of bone black required varies in different establishments from 1 to 4 tons to 100 of sugar. When the liquor ceases to run clear through the charcoal, a new filter is used, the sugar remaining in the old one is washed out with hot water, and the charcoal is removed to be recalcined, as before mentioned. Each time that the bone black is burned it deteriorates in quality, and finally becomes worthless. As the first cost of the article is about 8 cents a pound, its use is one of the heavy items of cost in the sugar manufacture; and it is said that one of the chief difficulties attending the refining of sugar in the sugar-growing countries is the inability to always obtain a good article of bone black. The sugar is now ready for the vacuum pan and the graining process. In the heater it is kept at a temperature of about 170° and is strongly agitated, which has the effect of promoting the whiteness and fineness so desirable in refined sugar. Transferred to the conical moulds, it is again well stirred, to cause the air to escape, which would otherwise render the sugar too porous. After the drainage is completed, some colored sirup is still mechanically held in the sugar. The process of liquoring, before referred to, is designed to remove this, and consists in pouring upon the sugar in the moulds a strong saccharine solution, obtained by dissolving the outer portions removed from previous loaves dissolved in water, and decolorized by passing through charcoal; this is continued till the drippings come away clear. An air pump is sometimes applied at the bottom to hasten

the process by exhaustion. The loaves taken from the moulds are finally dried, and dressed by turning off their outer portions in a lathe. The sirup boiled down again in the vacuum pan affords more crystallized sugar, which, as well as some prepared from raw sugar of inferior quality, and transferred directly from the vacuum pan to the moulds, sometimes dispensing with the liquoring, is termed crushed sugar. The best products of the refinery are the hard white loaves, containing the greatest amount of saccharine matter, though in this the sugar does not differ materially from the crushed variety. It is a common mistake to suppose that the crude sugars are the sweetest, which no doubt arises from the fact that these possess a more decided taste, which is derived from their impurities and is confounded with the sweetness of sugar.—Inferior sorts of sugar are made from molasses, which yields about 4 lbs. to the gallon. In the United States a few refineries are specially devoted to this manufacture. Molasses, being an incidental product, is of little value in the sugar countries, and is obtainable in unlimited quantities; and an inferior or damaged article fit for this application may often be cheaply purchased in the large markets. The process is similar to that of the other sugar refineries. As the manufacture of raw sugar has been improved upon the plantations, and the molasses consequently produced less rich in crystallizable sugar, this manufacture is not as profitable as it was formerly.—Among the modifications of the sugar refining process in use in different establishments worthy of notice are: 1, the chemical method of refining, originally practised by Prof. Daniell and afterward by Dr. Scoffern; and 2, the method of separating the molasses from the sugar by centrifugal action. The first consists in the use of a solution of basic acetate of lead for precipitating the coloring and foreign matters in the saccharine juice. The excess of lead is rendered insoluble by sulphurous acid gas, and the excess of this gas is removed by boiling. This renders the use of animal charcoal unnecessary, but the treatment of the juice with a poisonous salt of lead should only be intrusted to persons of chemical skill. The centrifugal machine used instead of the draining moulds consists of a drum of wire gauze attached to a central shaft which can be made to revolve rapidly, the whole enclosed in an outer casing of iron. The sugar prepared for the purpose is put into this cylinder and rapidly swept round, causing the molasses to escape through the meshes.—*Beet Root Sugar.* The beets cultivated in preference to other sorts in Europe for the manufacture of sugar are varieties of the white Silesian, yielding a juice richer in sugar and more free from salts than that of other kinds of beet. The weight of the larger ones is about 5 lbs. each; and the yield per acre in France and Belgium is 14 or 15 tons, and about Magdeburg 10 to 12 tons of beets richer in sugar. The crop is a success-

ful one over most of Europe, but more particularly N. of lat. 45°, and upon light dry soils, in a dry atmosphere. The richness of the juice is injured by direct application of manures to the growing crop, and it is less in large beets than in small ones. When the leaves begin to die, the beets are dug, the heads cut off, and the roots are thrown together and covered to protect them from light and frost. They may be thus kept for some time, though there is always risk of portions of the sugar passing into the uncrystallizable variety. The proportion of sugar contained in the fresh root varies from 5 to 12 per cent., and the product in a large way is usually about 6 per cent., sometimes 7½. The other contents of the root are: water, 83 to 94 per cent.; ligneous fibre and albumen, 2.5 to 5 per cent.; together with a small proportion of what is supposed to be pectine, and a trace of mineral substances. Taken to the factory, the beets are first washed clean in a cage revolving on a horizontal axis, and partly immersed in water; and when washed they are discharged by the action of the machine itself. As the juice cannot be forced out from the cells by compression alone, it is found necessary to tear open the cellular tissue, and this is done by a grating machine of the form of a rotating drum, the inner surface of which is studded with teeth. The pulp is then subjected to powerful hydraulic pressure. Maceration has also been employed to separate the juice. For this purpose the beets are cut into thin slices and put into a cistern with about their own bulk of hot water. In half an hour the liquor is let down upon other slices in another cistern, and so on through 3 to 5 vessels, until it acquires a density of 5½ to 7° B. By this process the juice is rendered very weak, apt to ferment, and requires much fuel to concentrate it. Another method practised near Heidelberg is, as soon as the beets are gathered and washed, to cut them into small rectangular pieces and dry them upon floors. Their bulk is thus reduced about 84 per cent., leaving 16 of dry matter, which may be kept for any time and transported to any distance. The sugar is then extracted by infusion or by maceration through a long series of vessels. The factory where this operation is carried on at Waghäusel is of immense extent, the buildings covering 12 acres of land; and in 1855 it employed 3,000 people. The infusing vessels, 20 in number, are 12 to 14 feet deep and 7 wide. The beets cost only 7d. per cwt., and when dried produce about 46 per cent. of sugar. The capital invested was 80,000,000 francs. The juice, however obtained, is rendered alkaline by the addition of lime water, and is then boiled. Excess of lime is removed by converting it into a sulphate, by the addition of ammonia alum, and the alumina set free aids the clarification. Another method is to pass a current of carbonic acid gas from an enclosed coke fire through the liquid, thus converting the lime into a carbonate. The subsequent processes of filtration, concentration, and granulation are

similar to those already described. Various methods of evaporation have been devised in place of the vacuum pan.—*Maple Sugar.* Several species of the maple afford, when the sap begins to flow in the spring, a juice containing crystallizable sugar. That yielding the richest juice is the *acer saccharinum*, the rock or sugar maple. The swamp or river maple, known also as the white or soft maple, produces a juice of inferior quality, but which is sometimes employed in sugar making. (See MAPLE.) The manufacture is stated to have originated in New England about the year 1752. It thence extended throughout the wooded portions of the country where the sugar maple abounds, particularly in the north-eastern states, New York, Michigan, Pennsylvania, and Ohio, and on the range of the Alleghenies further south. It is carried on in Canada both by whites and Indians. The tree is found in groves called sugar orchards, associated with scattering birch and other hard wood varieties, where the soil is good. At the proper season, usually in February and March, when the days begin to grow warm and the nights are frosty, the sugar makers resort to the woods, taking with them the few utensils they require, as large iron kettles, $\frac{1}{4}$ -inch angers, casks, buckets, and axes. They construct rough sheds over the boiling places, and if need be others for their own accommodation. Small open troughs hollowed out of the pine have been already prepared and distributed near the trees. With the angers they bore 2 holes in each tree a few inches apart, about 2 feet above the ground, taking care to penetrate not more than half an inch into the white wood. Into the holes they introduce split pieces of elder, from which the pith is removed to make a channel for the sap to flow; through this it gradually drips and collects in the trough placed below to receive it. The troughs as they fill are taken to the camp, and the juice is poured into casks to be transferred to the kettles. The boiling is actively kept up, and the scum which rises is removed; more sap is added as the liquid evaporates, till a considerable portion is converted into thick sirup, when it is cooled and filtered through woollen cloth. It is then boiled again in a smaller kettle, and when it

has attained the proper consistency for granulating it is turned into the moulds, which are commonly made of birch bark. The molasses soon drains away and leaves the sugar perfectly dry and hard, of a dark brown color, and of a peculiar pleasant taste. The juice of the maple is much more free from salts and other ingredients than that of the beet. The sugar is mostly consumed in its raw state, considerable quantities being sold in small cakes and eaten like candy. It may be easily refined and converted into the best white sugar.—*Production.* The total production of sugar has been estimated as follows in tons for the countries and years named:

CANE SUGAR.

Countries.	1882-'4.	1886-'7.	1888-'9.
Cuba.....	849,503	869,610	415,000

Total of both kinds	1,452,612	1,357,605	1,665,000

Louisiana produces the great bulk of the sugar crop of the United States. It is there a fluctuating crop, and yielded an average from 1822 to 1825 of about 30,000 hogsheads annually. It afterward increased, amounting in 1842-'3 to 140,816 hogsheads, the next year to 100,846, and in 1844-'5 to 204,913. Its further progress is indicated in the table below. The hogshead, when the weight in pounds is not given, is rated at 1,000 lbs. of sugar; it also contains from 40 to 50 gallons of molasses:

Years.	Total crop.		Av. price per hogshead.	Total value.	Exports from New Orleans.	
	Hogsheads.	Pounds.			To Atlantic ports.	To western states.
1842.....	186,650	186,650,000	\$55	\$10,265,750	79,000	75,000
1843.....	140,000	140,000,000	70	9,800,000	45,500	70,000
1844.....	240,000	240,000,000	40	9,600,000	84,000	115,000

Wisconsin.....	9,574	610,976
Minnesota territory.....	2,950
New Mexico.....	4,286
Total.....	247,777	12,700,584	84,258,486

The production of molasses from the sorghum has become very large since the introduction of this plant in 1856; and in Ohio in 1861 it is reported to have amounted to 8,000,000 gallons, worth 60 cents a gallon. The production of sugar in Cuba in 1860 was 503,680 tons, made on 1,365 estates, of which 691,917 acres, more than half their whole extent, were devoted to this crop. The importations of foreign sugars into the United States amounted in the first years of the 19th century to from 30,000,000 to 55,000,000 lbs., the average being double what it was in 1790, '91, and '92. In 1808 they amounted to 85,000,000 lbs., but did not reach the same figures again until 1822. In 1831 they first exceeded 100,000,000 lbs. The table below presents the imports and exports of all the sugars and of candy for the years named, collected from the U. S. treasury reports. The large importation of 1857 is a direct result from the short crop of Louisiana of the preceding year. The figures are for the years ending June 30:

Years.	Imports, lbs.	Value.	Exports, lbs.	Value.
1857....	776,987,005	\$42,768,917	90,070,048	\$3,744,981
1858....	519,086,256	22,480,523	81,546,284	5,143,659
1859....	635,612,491	30,553,861	40,167,410	2,808,160
1860....	664,793,448	31,076,517	38,492,101	2,555,767

The next table, from the estimates of the New York "Shipping and Commercial List," presents

the actual consumption of cane sugar in the United States for the years named, ending Dec. 31, in tons of 2,240 lbs. each, the exports being deducted from the gross receipts:

Years.	Foreign.	Domestic.	Total.
1852.....	196,556	113,650	815,217
1853.....	200,810	172,879	873,959
1854.....	150,854	284,444	855,298
1855.....	192,604	186,148	877,758
1856.....	255,292	128,468	878,760
1857.....	241,765	29,000	280,765
1858.....	244,768	143,684	888,492
1859.....	228,084	192,150	481,184
1860.....	298,950	118,881	415,231
1861.....	241,420	122,899	563,519

Average increase for the above 10 years, 1.54 per cent. The consumption of molasses has been estimated as follows:

Years.	Total, galls.	Foreign, galls.
1850.....	37,019,249	24,806,949
1851.....	43,949,013	28,228,278
1852.....	48,257,511	29,417,511
1853.....	55,586,821	28,576,681
1854.....	56,492,019	24,487,019
1855.....	47,266,065	25,583,428
1856.....	39,005,878	28,014,578
1857.....	28,508,794	22,268,404
1858.....	45,160,164	24,793,874
1859.....	54,260,970	25,229,210
1860.....	47,818,577	28,734,205

While the importation and exportation are both largely increasing, the introduction of foreign refined sugars is not half so great as it was 20 years since. This branch of home manufacture has been greatly extended in late years, refineries of the largest size being in operation in many of the cities on the seaboard and the large rivers of the West. The business is encouraged by the drawback of duties allowed on refined sugar exported, the product of foreign sugars on which the duties have been paid.—The following works may be referred to for further information in regard to sugar: Evans's "Sugar Planters' Manual" (1847); Wray's "Practical Sugar Planter" (1848); Scoffern's "Manufacture of Sugar in the Colonies" (1849); Leon, "Art of Manufacturing and Refining Sugar" (1850); Kerr's "Cultivation of the Sugar Cane" (1851); Tomlinson's "Cyclopædia of Useful Arts;" and "Statement of the Sugar Crop made in Louisiana" (annual reports), by P. A. Champomier. The manufacture of beet root sugar is described by Dumas in his *Traité de chimie appliquée aux arts*, vol. vi.; by Payen, *Chimie industrielle*; and by Duveau, *De la fabrication du sucre de betterave*.

SUGAR OF LEAD, neutral acetate of lead (PbO, C₂H₃O₂, 8Aq), a compound of 1 equivalent of acetic acid, 51; 1 of protoxide of lead, 111.6; and 8 of water, 27 = 189.6. This salt is prepared by dissolving in leaden boilers, with the aid of heat, pure litharge in strong vinegar, until this will take up no more. On cooling, the salt crystallizes in right rhombic prisms, which are sometimes transparent; the crystals generally form a confused mass of minute needles of a yellow tinge. They are purified and whitened by repeated solution and crystallization. The proper proportions of the ingre-

dients are 325 parts of finely ground and sifted oxide of lead, and 575 parts of strong acetic acid of 7° Baumé, which should afford 960 parts of crystallized sugar of lead. The salt is without odor, but possesses a sweetish, astringent, metallic taste, whence its name. It effloresces slightly in the air, and at a temperature above 212° F. it loses its water of crystallization, and is slowly converted into carbonate of lead. It dissolves in alcohol, in quantities of cold water variously stated at from $\frac{1}{16}$ to 4 times its weight, and much less boiling water. The solution is clear if the water is pure and free from carbonic acid. Sugar of lead is largely employed in dyeing and calico printing, being used to prepare with alum the red mordant, acetate of alumina. It is a powerful medicine, largely administered for its astringent and sedative properties. In over doses it is an irritant poison, the immediate effects of which however are sometimes obviated by the vomiting it occasions. It has a powerful effect in checking hæmorrhages, and is exhibited in a variety of diseases attended with irritability of the stomach, ulceration of the intestines, &c. It has proved very efficacious in checking mercurial salivation of long standing. It is commonly administered in pills combined with opium. Sugar of lead is also beneficial in external applications for allaying superficial inflammation: The lotion is sometimes advantageously prepared with the addition of an equal quantity of opium to that of the sugar of lead. The continued use of sugar of lead in small doses sometimes produces the diseases known as lead colic and lead palsy.

SUGAR OF MILK. See MILK, vol. xi. p. 501.

SUHM, PETER FREDERIK VON, a Danish historian, born in Copenhagen, Oct. 18, 1728, died there Sept. 7, 1798. He studied jurisprudence, and received an appointment in 1748 in the supreme court, but declined it. He resided in Drontheim from 1751 to 1765, applying himself to northern history and antiquities. After his return to Copenhagen, he published tales, poems, moral treatises, and elaborate historical works, the most important of which are a history of Denmark (11 vols., Copenhagen, 1782-1812), which extends only to the year 1819; a critical history of ante-Christian Denmark; and works on northern mythology and on the origin and migration of the northern peoples.

SUICIDE. See FLEO DE SE.

SUIDAS, a Greek lexicographer, supposed to have lived in the 10th century. Though the work of Suidas is usually called a "Lexicon," it contains articles on geography, biography, and history, under proper names, which are given coördinately with the words of the Greek language. The work is in some respects defective and inaccurate, but of great value in the study of the literary history of antiquity. It contains many extracts from ancient Greek writers, some of whom are lost, and information in relation to them is not elsewhere found.

The work appears to have received additions from various hands. The first edition of Suidas was published by Demetrius Chalcondylas (fol., Milan, 1499); the best is that of T. Gaisford (3 vols. fol., Oxford, 1834).

SULIOTES, a people of mixed Arnaout and Greek descent, who formerly dwelt in the southern part of the pashalik of Janina, the ancient Epirus. They derive their origin from a number of families which in the 17th century fled from the tyranny of the Turks and settled in an almost inaccessible valley of the Cassiopeian mountains. In the second half of the 18th century they numbered 560 families, embracing about 10,000 souls, and dwelt in 70 villages, the chief of which was Suli, which gave name to the district. They belonged to the Greek church, and their language was Greek, although they also spoke Albanian; their form of government was democratic. They were divided into about 80 tribes or clans. In war they usually fought as skirmishers, and the head of each clan was its captain, who commanded them in battle, subject to a general officer called polemarch, who was elected by vote. In the war of 1787-'92 between Russia and the Porte, the Suliotes strongly supported the former power, defeated in 1789 the troops sent against them by Ali Pasha of Janina, in 1790 ravaged Acarnania to the Achelous, and afterward invaded Arta and Janina, and aided the corsair Lambro Canzani with men and money. Deserted by the Russians after the peace of 1792, they fought desperately against the troops of Ali Pasha, who was determined to exterminate them, and at first were so successful that he concluded with them a truce which lasted a few years. In May, 1801, he renewed his design of extermination, and after a bloody war succeeded in reducing them, the men being put to the sword in large numbers, and the women throwing themselves into the river rather than fall into the hands of their enemies. A few continued to dwell in their deserted villages, but the great majority of the survivors of the war, numbering about 4,000, in 1803 retired to Parga. This place, through the threats and intrigues of Ali Pasha, they were compelled to leave, and betook themselves to the Ionian islands. When in 1820 Ali Pasha, in revolt against the Porte, was hard pressed by the Turks under Koorshid Pasha, and deserted by the Albanians, he recalled the Suliotes. The tyrant of Janina fell in 1822, but the Suliotes remained true to the cause of Grecian liberty. In spite of the heroic efforts of their leader, Marco Bozzaris, the Suliotes were hemmed in in their inaccessible valley; expeditions sent to their relief failed of success; and at last, Suli being taken, Sept. 4, 1822, the Suliotes willingly accepted the offer of an asylum from the governor of the Ionian islands. About 2,000 were carried in English ships to Cephallonia; the remainder dispersed among the mountains. When Lord Byron went to Greece, he raised and equipped at his own ex-

pense a corps of 500 men from this people, for whom he had great admiration.

SULLA. See SYLLA.

SULLIVAN, the name of counties in 6 of the United States. I. A S. W. co. of N. H., bounded W. by the Connecticut river, which separates it from Vermont, and drained by the Ashuelot and other streams; area, 570 sq. m.; pop. in 1860, 19,041. The surface is hilly, and in some parts mountainous, and the soil fertile in the valleys. There are several small lakes or ponds. The productions in 1850 were 122,609 bushels of Indian corn, 182,720 of potatoes, 98,008 of oats, 64,088 tons of hay, and 580,875 lbs. of butter. There were 11 woollen and 3 cotton factories, 10 grist mills, 26 saw and planing mills, 16 tanneries, 1 paper mill, 2 newspaper offices, 26 churches, and 5,103 pupils attending public schools. It is traversed by the Sullivan railroad. Capital, Newport. II. A S. E. co. of N. Y., bounded S. E. by the Shawangunk and W. by the Delaware river, which separates it from Pennsylvania, and drained by the Neversink and other streams; area, 890 sq. m.; pop. in 1860, 32,885. The surface is rough and mountainous, and there are several small lakes. The soil is well adapted to grazing, and along the streams is fertile. The productions in 1855 were 109,883 bushels of oats, 102,594 of Indian corn, 75,153 of rye, 65,571 of buckwheat, 108,188 of potatoes, 73,298 of apples, 40,716 tons of hay, and 981,927 lbs. of butter. There were 16 grist mills, 145 saw mills, 39 tanneries, 1 furnace, 8 newspaper offices, 46 churches, and 153 schools. It is intersected by the Erie railroad and the Delaware and Hudson canal. Capital, Monticello. III. A N. E. co. of Penn., drained by the Loyalsock, Muncy, and other creeks; area, 480 sq. m.; pop. in 1860, 5,637. The surface is hilly and well timbered, affording a large quantity of lumber for export. The soil is productive. The Alleghany mountain range traverses the S. part. The productions in 1850 were 21,487 bushels of Indian corn, 11,959 of wheat, 4,719 tons of hay, and 90,250 lbs. of butter. There were 17 saw mills, 5 grist mills, and 46 churches, and in 1860 992 pupils attending public schools. Capital, Laporte. IV. A N. E. co. of Tenn., bordering on Va., and intersected by the Holston river; area, 800 sq. m.; pop. in 1860, 13,553, of whom 1,074 were slaves. The surface is very hilly and well timbered, and the soil fertile. The productions in 1850 were 873,698 bushels of Indian corn, 69,937 of wheat, 162,914 of oats, and 99,299 lbs. of butter. There were 28 churches, and 825 pupils attending public schools. Iron ore and coal are found. It is intersected by the Virginia and East Tennessee railroad. Capital, Blountsville. V. A S. W. co. of Ind., bordering on Ill., from which it is separated by the Wabash river; area, 480 sq. m.; pop. in 1860, 15,063. The surface is generally level, and the soil fertile. The productions in 1850 were 742,186 bushels of Indian corn, 56,725 of wheat, 75,879 of oats, and 3,751

tons of hay. There were 2 newspaper offices, 21 churches, and 2,047 pupils attending public schools. Capital, Sullivan. VI. A N. co. of Mo., drained by Locust creek and other streams; area, 650 sq. m.; pop. in 1860, 9,198, of whom 102 were slaves. A considerable portion of the county consists of prairie land, and the soil is fertile. The productions in 1850 were 176,789 bushels of Indian corn, 11,482 of wheat, 15,974 of oats, 1,201 tons of hay, and 85,648 lbs. of butter. Capital, Milan.

SULLIVAN. I. JOHN, an American general in the revolutionary war, born in Berwick, Me., Feb. 17, 1740, died in Durham, N. H., Jan. 23, 1795. For several years before the revolution Gen. Sullivan practised law with great success in Durham, and from 1772 held a provincial commission as major. In 1774 he was a member of the first general congress, and in December of that year, with John Langdon, led a force against Fort William and Mary, near Portsmouth, took possession of 100 barrels of gunpowder (afterward used at the battle of Bunker hill), 15 cannon, all the small arms, and other stores, and carried them up into the country, concealing a portion of them under the pulpit of the Durham meeting house. This was the first act of armed hostility committed in the colonies. In June, 1775, he was appointed by congress a brigadier-general, and commanded on Winter hill at the siege of Boston. After its evacuation, he was despatched with reinforcements to the northern army in Canada, where, a few days after the death of Gen. Thomas, he took command, and in effecting his retreat from the province displayed great military skill and resolution. Congress having appointed Gates to that department, Sullivan proceeded to Philadelphia, and soon joined the main army under Washington. Commissioned by congress as major-general, he acted under Putnam on Long island, and by a combat of two hours in the woods (Aug. 27, 1776), aided by Stirling's vigorous defence on the right, contributed to the preservation of the American army. He was taken prisoner, but, having been exchanged for Gen. Prescott, was with Washington at Westchester during the autumn. After Gen. Lee's capture, Sullivan took command of his division, and led the right at Trenton on Christmas night, 1776. He did efficient service at Princeton, and during the rest of the season protected the lines at Morristown. On Aug. 22, 1777, he made a descent on Staten island, the entire success of which was prevented by misconception of his orders, and which, though rash, was subsequently justified by a court of inquiry and by a vote of congress. He commanded the right wing at the battle of Brandywine, and was fully exonerated by Washington and Lafayette from the charge of being responsible for the defeat that ensued. He defeated the British left at Germantown, driving them two miles; but mistakes on the American left, occasioned by fog, changed a victory into a repulse. In

1778 Sullivan commanded in Rhode Island. After long preparations, every thing was ready for an attack upon the British lines at Newport in August, when, deprived of the expected cooperation of the French fleet under D'Estaing, upon which its success depended, Sullivan was obliged to raise the siege; but at Butts's hill, on the 29th, he repulsed the enemy, and withdrew from the island with slight loss. In 1779, being assigned to the command of an expedition against the Indians of the Six Nations, he laid waste their settlements, and on Aug. 29 inflicted a severe defeat on the Indians under Brant and Tories under Sir John Johnson, at Newtown, near the present site of Elmira, in western New York. Gen. Sullivan's health being shattered by fatigue and exposure, he resigned after the termination of this important expedition, for which he received a vote of thanks from congress. In the autumn of 1780 he again took his seat as a member of congress, and was chairman of the committee which aided in suppressing the mutiny of the Pennsylvania troops in 1781. Returning to New Hampshire, he was appointed attorney-general, and thrice elected president of the state. In the troubles of 1786 he saved the state from anarchy by his intrepidity and good management, and in 1788 secured the adoption of the federal constitution. In 1789 he was appointed by Washington federal judge of New Hampshire, which office he held till his death. His life was written by O. W. B. Peabody, in Sparks's "American Biography." II. GEORGE, LL.D., an American lawyer and statesman, son of the preceding, born in Durham, N. H., in 1774, died in Exeter, N. H., June 14, 1838. He was elected a member of the state legislature in 1805 and 1813, of congress in 1811, and of the state senate in 1814 and 1815; and he was attorney-general of the state from 1805 to 1807, and from 1816 to 1835. He was one of the most distinguished advocates of his time. III. JAMES, governor of Massachusetts, brother of Gen. John Sullivan, born at Berwick, Me., April 22, 1744, died in Boston, Dec. 10, 1808. After practising law for some years at Biddeford, Me., he was appointed king's attorney for York co.; but he took an early and decisive part on the side of the colonies at the commencement of the revolutionary struggle. He was a member of the provincial congress of Massachusetts (of which Maine then formed a part) in 1775, and with two others executed a difficult commission to Ticonderoga. In the following year he was appointed a judge of the superior court, and in 1779-'80 was a member of the convention which framed the constitution of the state. In 1783 he was chosen a member of congress; and he was repeatedly elected a representative of Boston (to which place he had removed) in the legislature. In 1787 he was a member of the executive council and judge of probate for Suffolk co., and from 1790 to 1807 was attorney-general of the state; and in the latter year he was elected governor by the

republican party, and reelected in 1808. He was one of the commissioners appointed by President Washington for settling the boundaries between the United States and the British provinces. Governor Sullivan was the projector of the Middlesex canal, which was constructed under the superintendence of his son, John L. Sullivan; and he was the author of several works, mostly on legal or political subjects, including a "History of the District of Maine." IV. WILLIAM, LL.D., son of the preceding, born in Saco, Me., Nov. 12, 1774, died in Boston, Sept. 3, 1839. He was graduated at Harvard college in 1792, studied law, and became a leading practitioner at the Suffolk bar, over whose association he presided for many years. He was constantly a member of one or the other branch of the state legislature. He published numerous addresses, and was the author of "Familiar Letters on Public Characters and Events from 1783 to 1815" (12mo., Boston, 1834); "Historical Causes and Effects, from the Fall of the Roman Empire to the Reformation in 1517" (8vo., Boston, 1838); "The Public Men of the Revolution" (with a biographical sketch by his son, J. T. S. Sullivan, 8vo., Philadelphia, 1847); and of "Historical," "Moral," and "Political" class books. V. JOHN L., an American engineer and inventor, brother of the preceding, born in Saco, Me., April 9, 1777. He was in early life engaged in mercantile business, afterward travelled in Europe, studying the construction of canals in France and England, and in 1804 was appointed agent and engineer of the Middlesex canal. This work, designed to provide a navigable channel between Boston and Concord, N. H., by canal and the improvement of the Merrimac, presented great difficulties, but was successfully and economically completed in 7 years. He next turned his attention to steam navigation, and invented the steam tow-boat, for which he received a patent in 1814, in preference to Robert Fulton, who applied for it at the same time, his priority of discovery being fully sustained. This invention he first tried on the Middlesex canal, and afterward put into practical operation in the rivers of Georgia and South Carolina, Fulton's monopoly preventing its introduction at that time in New York. In 1824 he was appointed by President Monroe associate civil engineer of the board of internal improvements, which post he resigned the next year, after making a report on the practicability of a canal across the Alleghanies. In 1830 he engaged in the regular practice of medicine at New Haven, for which he received a diploma, afterward adopted the homoeopathic system, and made several important inventions and discoveries both in medicine and surgery. In 1847 he removed to New York, where he still resides (1862).

SULLIVAN'S ISLAND, an island in the harbor and 6 miles below the city of Charleston, S. C. Many of the wealthy citizens of Charleston have residences here. Fort Moultrie is sit-

uated on this island, and is a costly and strong fortification, commanding the approach to the main harbor. (See MOULTRIE, Fort.) On Dec. 26, 1860, after the secession of South Carolina, the fort was evacuated by the U. S. troops under Major Anderson, who retired to Fort Sumter. Fort Moultrie was at once occupied by South Carolina troops, and the state authorities proceeded to erect batteries at different points on the island, the guns of which and of the fort were subsequently used in the attack upon Fort Sumter.

SULLY, MAXIMILIEN DE BÉTHUNE, baron de Rosny, duke of, a French soldier and statesman, born at Rosny, near Mantes, Dec. 18, 1559, died at his country seat of Villebon, Dec. 22, 1641. He belonged to a noble Protestant family, and when 16 years old was introduced to King Henry of Navarre, whom he followed in all his wars, and whose chief adviser he became. When his master, on the death of Henry III., claimed the throne of France, of which he was the lawful heir, Rosny, although himself a thorough Protestant, advised the new king to turn Catholic in order to reconcile the majority of the nation to his cause. Being sent on a secret mission to Queen Elizabeth of England, he succeeded in securing her assistance to Henry IV., to whom he also did good service by his skill as an engineer, being instrumental in taking Dreux in 1593, Laon in 1594, La fère in 1596, and Amiens in 1597. In 1597 he was appointed superintendent of finance, and became in fact the chief minister of Henry IV., the most important parts of the administration devolving upon him. He commenced with reforming the financial system, which had been deranged by dilapidations and robbery; by strict economy and the rigorous control to which the subordinate officers were subjected, he succeeded not only in meeting the heavy current expenses of the government, but in cancelling the public debt, which amounted to 882,000,000 livres, remitting 20,000,000 of taxes in arrears, alleviating the annual taxation, and gathering a reserve of 17,000,000, which was deposited in the Bastille. Meanwhile he fostered agriculture, made the grain trade free, suppressed tolls and prohibitions, built or improved highways and roads, constructed canals, and gave encouragement to drainage and mining. He was created duke of Sully by the king in 1606, previous to which he had been known by the name of Rosny. Under his administration France was the most prosperous country in Europe when Henry IV. fell under the dagger of Ravallac. Sully for a while longer retained his post as chief minister; but his severity and rigid principles becoming obnoxious to Maria de' Medici and her advisers, he left the court, resigned most of his offices and dignities, and retired to private life. From Cardinal Richelieu he received in 1634 the title of marshal of France. During his retirement he composed his personal memoirs, which were written down under his supervi-

sion by 4 secretaries, and were published under the title of *Sages et royales économies d'état* (fol., 1684; 4 vols. 8vo., 1662; English translation by Mrs. Lenox, reprinted, 4 vols. 12mo., London, 1854).

SULLY, THOMAS, an American painter, born in Horncastle, Lincolnshire, England, in June, 1788. He emigrated to the United States with his parents, who were players, in 1792, and at the age of 15 commenced the study of painting in Charleston, S. C. In 1808 he established himself as a portrait painter in Richmond, Va., and removed a few years later to New York, where he entered upon a lucrative practice. In 1809 he settled in Philadelphia, which has since been his home. His reputation as one of the leading American portrait painters is founded upon numerous works produced in the chief cities of the United States. Among his large works may be mentioned full-length portraits of George Frederic Cooke as Richard the Third, Dr. Benjamin Rush, Commodore Decatur, Thomas Jefferson, and Lafayette. His well known picture of "Washington crossing the Delaware" is now in the possession of the Boston museum. During a visit to England in 1887-'8 he painted a full-length portrait of Queen Victoria, esteemed a very faithful likeness. Mr. Sully has until recently continued actively engaged in the pursuit of his art.

SULPHATE. See **SULPHURIC ACID**.

SULPHATE OF BARYTA. See **BARYTA**.

SULPHATE OF COPPER. See **BLUE VITRIOL**, and **COPPER**, vol. v. p. 682.

SULPHATE OF IRON. See **COPPERAS**.

SULPHATE OF LIME. See **GYPSEUM**.

SULPHATE OF MAGNESIA. See **EPSOM SALT**.

SULPHATE OF MANGANESE, an artificial compound of sulphuric acid and manganese, largely employed by calico printers. It is obtained in solution on lixiviating a mixture of the peroxide of manganese, bituminous coal, and sulphuric acid, which has been made into a paste and calcined at a heat of 400° F. The salt crystallizes in prisms of pale amethyst color, which have an astringent bitter taste and are dissolved in 2½ parts of water. They consist of protoxide of manganese 31.93, sulphuric acid 35.87, and water 32.20.

SULPHATE OF SODA. See **GLAUBER'S SALT**.

SULPHATE OF ZINC. See **ZINC**.

SULPHITE. See **SULPHUROUS ACID**.

SULPHUR (Lat. *sulfur* or *sulphur*), an elementary crystalline substance, of yellow color, inflammable, fusible, volatilizable, brittle, occurring abundantly in a native state in volcanic districts and some other localities, and in combination with the metals forming the common class of ores known as the pyrites and other sulphurets; symbol, S; chemical equivalent, 16. Combined with oxygen, it forms sulphurous and sulphuric acids, the numerous salts of which are known respectively as sulphites and sulphates. In various combi-

nations sulphur is found in vegetable and animal bodies. It was known to the ancient Greeks by the name of *θεῖον* and other designations indicating its purification by fire. They employed it in medicine, in expiation and lustration, and for various uses in the arts, as for fumigating woollens to render them whiter and softer, and for making matches, purposes for which it is still used.—Native sulphur occurs in amorphous masses in sedimentary formations, sometimes crystallized in transparent octahedrons with a rhombic base; but its crystals artificially made assume other forms. It is also met with in fine powder deposited by sublimation around the mouths of volcanoes; and again in concretionary or stalactitic forms of melted sulphur; and in similar forms, friable and almost white, in deposits left by thermal waters containing sulphuretted hydrogen. In general sulphur is distinguished from all other minerals by its yellow color and adamantine lustre; and if these characteristics are not sufficient, it is recognized by its bluish flame when heated to 450° to 500° F., and peculiar suffocating fumes emitted in burning. When pure it is without taste and emits no odor until heated. It is insoluble in water, but dissolves in oil of turpentine, sulphuret of carbon, fat oils, ether, petroleum, and fused paraffine. It is a non-conductor of electricity, and a bad conductor of heat. By friction it becomes negatively electric. The native sulphur is of hardness 2.3, and specific gravity 2.07. At 239° F. it melts, and when run in moulds into round sticks it forms the brimstone (burnstone) of commerce. The sticks are of less density than the native sulphur, and have so little coherence as sometimes to crackle and fall in pieces from unequal expansion when grasped with a warm hand.—The changes which sulphur undergoes, or the different allotropic states it assumes with different degrees of heat, are very remarkable. When melted and the temperature is raised, its color deepens and the liquid becomes viscid. At nearly 500° it is of a deep brown, and so thick that it will not run out if the vessel containing it is inverted. At higher temperatures it again becomes thin, until it reaches the boiling point, which according to Regnault is at 752° (Dumas, 824°), when it begins to pass off in a deep yellow vapor. If, while it begins to grow thin the second time at about 470°, it be poured into water, it remains even when cold in its plastic condition, having the soft elasticity of the gluten of wheat flour, which it much resembles except in color. In this state it continues for several hours before becoming hard. Hollow shells lined with beautiful crystals of sulphur may be obtained by pouring the melted sulphur while in the first liquid stage into a vessel with sloping sides, and when a crust has formed breaking two holes through it on opposite sides, and pouring the liquid portion out through one of them. When cold, the mass is to be detached from the vessel and sawed in two. If the experiment has been well per-

formed, each half will present a radiating and interlaced mass of brownish yellow needles belonging to the oblique prismatic form, attached at their bases to the outer crust. Exposed to the air, their transparency disappears in a few days, and the crystals losing their coherence crumble into an opaque mass consisting of minute rhombic octahedrons. The specific gravity of the artificial crystals is 1.98.—The native sulphur of commerce is derived chiefly from Sicily, where the most productive mines are those of Villarosa, Santa Catalda, and Terra di Falco. At the Italian exhibition at Florence in 1861, the products of the sulphur mines were very conspicuous. The annual product of all the Italian mines was stated to be 800,000 tons, valued at 80,000,000 francs, being 10 times as great as it was in 1830. Sicily produces the greater portion, and the Romagna 8,000 tons. The product is supposed to be increased one fifth by large furnaces of a new form recently introduced, which reduce the usual loss of sulphur consequent upon the unnecessary conversion of a considerable part of it into sulphurous acid. The sulphur is found among beds of black, bituminous, slaty marl and limestone belonging to the chalk formation, associated with beds of gypsum and rock salt. It occurs in bunches and thin irregular layers, which generally follow the lines of stratification. Their occurrence is usually in the upper members of the chalk, where they are overlaid by the tertiary. The sulphurous strata are sometimes so thick as to be followed by drifts like coal beds, and solid pillars of sulphur are occasionally left as a support for the hanging wall or roof. Other localities of similar character are Conil, near Oadiz, in Spain, Bex in Switzerland, and Oracow in Poland. The crater of Vulcano and the Solfatara near Pozzuoli afford large quantities of sublimed sulphur. In the crater the sulphur collects upon the walls, and in the *débris* with which it is filled. In the bottom the loose materials are explored to the depth of 30 feet, or as low as the temperature will admit. The materials taken out are subjected to distillation, for recovering the sulphur as the sublimation goes on. Fresh supplies are obtained in 25 to 30 years. Almost all volcanoes deposit sulphur, but, though apparently in large quantities, it sometimes proves on examination insufficient to pay for extraction. Another source of sulphur is iron pyrites (the bisulphuret of iron), a common ore in all mining regions. This, which contains 54.5 of sulphur, may be made to yield about 27 per cent.; but there is little inducement to prosecute the manufacture, for the sulphur costs much more than the natural product obtained from Sicily, and is moreover often contaminated with arsenic, sometimes to the amount of 7 per cent., while the impurities of fine Sicilian sulphur are earthy matters only, and do not amount to more than 3 per cent. It is important to know, however, that such resources are at hand for supplying sulphur as the vast repositories of sulphurous ores, and

the still greater beds of gypsum (sulphate of lime), which by processes well known might be made to produce this article. The waste residues of many chemical manufactures contain large quantities of sulphur in different combinations, which might add largely to the supply in case of any great increase of its price. Where pyritous copper is prepared upon a large scale for smelting, the sulphur is sometimes saved, either by distilling the ore in close vessels, or by roasting it in the open air in heaps of 2,000 tons or more. Such heaps are formed of fine ore at the bottom, covered with brush, and in the centre is placed a wooden chimney into which air passages from the sides are to open. The ore is piled upon the wood about 8 feet high, and covered with about 12 inches of fine ore. Fire is introduced by dropping live coals down the chimney. In a few days the sulphur begins to ooze forth from the surface of the heap, and collect in little excavations made upon it for its reception. From these it is bailed out and cast into moulds. The operation continues 5 or 6 months, producing about 20 tons of sulphur. A similar method is practised in separating the sulphur from its earthy associates at some of the mines where it is obtained in a native state. The heaps are, however, of comparatively small size and built up on prepared concave bottoms, and the whole is covered with fine earth to prevent the too rapid escape of the fumes. The sulphur as it becomes liquid collects in the bottom, whence it is run out into moulds shaped like large bricks. The residues of the operation, mixed with first products of inferior quality, are afterward distilled in upright pots which serve as retorts, a short wide tube from the upper portion of each pot carrying off the volatilized sulphur through the walls of the furnace into other jars of similar shape. From the bottom of these receivers the melted sulphur flows through short pipes into vessels containing water. The sulphur is further purified by a second distillation from iron retorts which discharge the fumes into chambers of brickwork. Upon the walls of these the sulphur condenses, forming the powder called flowers of sulphur. If the walls become hot, the sulphur melts and is run off into cylindrical wooden moulds, thus becoming roll sulphur or brimstone.—A preparation called milk of sulphur or precipitated sulphur, used chiefly in medicine, is made by boiling ordinary sulphur with slaked lime and water and adding hydrochloric acid, which unites with the lime and precipitates the sulphur. Separated from the liquid it is obtained in finely divided particles, slightly cohering together, of whitish color, faintly tinted with yellowish green. Some manufacturers fraudulently precipitate with sulphuric acid, thus producing a large mixture of sulphate of lime. The presence of this may be suspected from too sparkling a white color, and a grittiness when tried between the teeth, and is exposed if the whole is not volatilized by heat.—The uses of sulphur

are numerous. It is largely employed in the manufacture of sulphuric acid, and of vermilion, the artificial sulphuret of mercury. It is one of the three ingredients of gunpowder, and matches are coated with it, that by its ready ignition the fire may be held until by its combustion it is communicated to the wood. In bleaching woollen and silk goods and straw it is ignited in close chambers, which are provided with a ventilating draught of air through them, and is thus converted into sulphurous acid gas. It is used for taking impressions from seals and cameos, and for this purpose it should be kept for some time melted, so that it may assume the appearance of bronze. It is an excellent material for cementing iron posts or bars in stone, being much preferable to lead for this purpose, on account of the latter causing the iron to rust through galvanic action. The flowers of sulphur and milk of sulphur are largely employed for medicinal purposes. As the former often contains sulphurous acid, it should be first freed from this by washing in hot water. Its effects are laxative, diaphoretic, and resolvent. Applied externally in various forms, sulphur is readily absorbed, and when taken internally it is dissolved, and is given off through the pores of the skin, discoloring the blood under the nails, and tarnishing silver carried in the pockets, by superficial conversion of the silver into the sulphuret. It is given internally in some of the forms of asthma and chronic catarrhs and coughs; and in chronic rheumatism it is sometimes very beneficial. Combined with magnesia or bitartrate of potash, it is a safe and useful laxative in piles, habitual constipation, &c. It is a specific for the cure of some cutaneous diseases, especially that form known as *scabies*. For these it is employed both internally and externally, in the latter case sometimes in the form of sulphur ointment, and again as a sulphur bath, in which the person, except the head, is immersed in sulphurous acid gas. The brown viscid sulphur obtained by fusion is stated to be a much more active stimulant to the circulation, lungs, and skin than ordinary sulphur. A compound of 1 part of sulphur and 4 of iodine, produced by melting the two substances together in a glass flask at the temperature of boiling water, and rubbed into an ointment with lard, is an excellent preparation for the treatment of various cutaneous eruptions unattended with inflammation, such as psoriasis, lepra, scald head, &c. The efficacy of many natural medicinal waters is due to the combinations of sulphur they contain. Certain diseases of the vine, hops, &c., are sometimes cured by sprinkling sulphur over them.—Sulphur unites with different bodies, forming a variety of useful compounds, of which only some of the most important will be noticed. Those consisting of sulphur and metallic bodies are described under the heads of the several metals. (See also PYRRRUS.) Of its compounds with carbon, the most useful is that commonly known as the

sulphuret of carbon, or more properly the bisulphide of carbon (CS_2), discovered by Lampsadius in 1796. This is a transparent colorless liquid of an intensely disagreeable odor, produced by passing the vapor of sulphur through incandescent charcoal contained in an iron or porcelain tube. The substance is remarkable for its volatility, boiling at $110^\circ F.$, and evaporating rapidly at ordinary temperatures. It is a powerful solvent of oils and fatty matters, and may be used to extract these and numerous coloring substances from fabrics. It has been largely employed of late as a solvent of India rubber, and is now produced in large quantities for this purpose. It also dissolves phosphorus and sulphur; and its combination with the former has been proposed as a destructive inflammable material in warfare to be introduced into shells. (See GREEK FIRE, vol. viii. p. 472.) The dichloride of sulphur (S_2Cl_2), also a fluid body prepared by passing chlorine gas through melted sulphur and redistilled, is also used in the preparation of vulcanized India rubber. (See ΟΑΟΤΤΟΝΟΥ, vol. iv. p. 391.) If linseed or rape oil is mixed with $\frac{1}{10}$ its bulk of this liquid, and slightly warmed, a substance is produced precisely resembling India rubber, but quite insoluble in various bodies in which caoutchouc is dissolved. With hydrogen sulphur forms the gaseous body described in HYDROSULPHURIC ACID. With oxygen sulphur forms 7 acid bodies, of which the most important are the subjects of the two succeeding articles.

SULPHURETTED HYDROGEN. See HYDROSULPHURIC ACID.

SULPHURIC ACID, a compound of 1 atom of sulphur and 3 of oxygen, SO_3 , known in commerce as oil of vitriol. It forms several definite compounds with water, of which the one best known is the monohydrate, $SO_3 \cdot HO$. Some of the characteristic properties of these compounds are presented in the following table:

Compounds.	Chemical equiv.	Fusing point.	Boiling point.	Specific gravity.
Anhydrous, SO_3	40	$65^\circ F.$
Dihydrate, $2SO_3 \cdot HO$...	80	95°
Monohydrate, $SO_3 \cdot HO$...	49	51°	640°	1.842
Bihydrate, $SO_3 \cdot 2HO$...	58	47°	485°	1.780
Tetrahydrate, $SO_3 \cdot 3HO$...	67	..	845°	1.682

Hydrated or liquid sulphuric acid was known to the alchemists, and its discovery has been ascribed to Basil Valentine, a monk of Erfurt in Saxony, about the middle of the 15th century. It was obtained by distilling copperas or green vitriol in a retort at a red heat, the acid dropping from it in an oily liquid, whence the name, oil of vitriol. He also obtained it by burning sulphur under a bell glass moistened with water—a product he called *oleum sulphuris per campanam*; and he obtained it again under the name of oil of antimony by burning equal parts of sulphur, sulphuret of antimony, and nitre under a bell glass. In the present mode of manufacture, nitre and sulphur are burned together to produce this acid. This

method was proposed in 1740 by two French chemists, Lefèvre and Lémery, and adopted by Dr. Ward in his manufactory near London. He employed large globular receivers of glass, each containing a few pounds of water, and arranged with their necks projecting horizontally from the sand bath in which the vessels were placed. The sulphur with $\frac{1}{2}$ its weight of nitre was placed in a shallow dish standing just above the water, and when it was fired by a hot iron the necks of the receivers were closed with wooden stoppers. By repeating the process several times, a strong acid was produced at a less rate per pound than an ounce had previously cost. Lead vessels were substituted for glass by Dr. Roebuck of Birmingham about the year 1746, and since that time there has been no material change in the processes. Platinum stills for concentration were in use in the early part of the present century; and in 1818 Dr. Erick Bollman of Philadelphia (the Danish physician who had attempted with Mr. Huger of South Carolina to release Lafayette from the prison at Olmütz) made one of 700 ounces weight and a capacity of 25 gallons, which continued in use 15 years in the works of Mr. John Harrison. Sulphuric acid was manufactured in Philadelphia by Mr. Harrison previous to 1806, and in 1807 he had a leaden chamber 50 feet long and 18 feet wide and high, capable of making 8,500 carboys of acid annually. The manufacture of this and other chemicals is very extensively carried on in Philadelphia in numerous large establishments. It is also an important branch of manufacture in chemical works in other parts of the country; as in Newark, N. J., Roxbury, Mass., and various other places. —Sulphuric acid is the most important and extensively used in the arts of all the acids; and on account of its superior attraction for bases, it is employed for obtaining almost all the other acids by causing them to separate from their combinations. It is when pure a limpid, colorless, and odorless fluid, highly acid, and exceedingly corrosive. On the living fibre it acts as a powerful caustic. Its freezing point varies with the strength of the acid, and is several degrees below zero when concentrated. In congealing it crystallizes in 6-sided prisms, terminated by pyramids of 6 sides. Dufrenoy states that in this condition he has held it many minutes in the hand without inconvenience, and has measured its angles with the goniometer, finding them to be exactly 120° . The liquid acid chars most organic substances, absorbing the moisture they contain, for which it has a powerful affinity. So great is this that when exposed in an open saucer, it extracts from the atmosphere $\frac{1}{2}$ its weight in 24 hours, and at least 6 times its weight in a few months. At the same time it becomes dark-colored by the decomposition of organic substances in the dust that falls into it. Hence it is necessary to keep it protected from the air in bottles with glass stoppers. Its affinity for water is sometimes advantageously made

use of to aid the evaporation of liquids at low temperature, the two fluids in different vessels being placed under the receiver of an air pump, and a partial vacuum being produced. Water may thus be evaporated so rapidly as to freeze. The same property is also made available in various chemical operations in depriving gases, powders, &c., of moisture. If suddenly mixed with water much heat is given out, and when cool the mixture is found to occupy less space than the two liquids did separately. The greatest increase of heat is noticed when 4 parts by weight of the strongest acid are suddenly mixed with 1 of water, both at about 50° F. The temperature then rises to 300°; but if 4 parts of ice be mixed with 1 of sulphuric acid, a liquid is immediately produced with a temperature 4° below zero. Sulphuric acid is detected in solutions by adding chloride of barium, the acid expelling the chlorine and forming with the barium an insoluble sulphate. Sulphuric acid is a powerfully corrosive poison, acting instantly upon the throat and stomach, and causing intense agony and death. Its effects may be alleviated by immediately swallowing magnesia or chalk mixed with water. Impurities of several sorts are often present in the commercial acid, derived from the substances with which it comes in contact in its manufacture; such are the sulphates of potash and lead, nitrous acid, and arsenic. Sulphate of potash is sometimes purposely introduced to increase the density of the acid. Arsenic is found in acid produced from iron pyrites, and in some of English manufacture from 22 to 35 grains of arsenious acid have been separated in Philadelphia from 20 fluid ounces. The fixed impurities are readily detected and estimated by evaporating a weighed portion of the acid. The quantity of sulphuric acid in 100 parts of solutions is estimated by their specific gravities; and the following table, prepared by Dr. Ure, gives the proportion of dry and hydrated acid in solutions of the densities named, at 60° F.:

Specific gravity.	Dry acid.	Hydrated acid.	Specific gravity.	Dry acid.	Hydrated acid.
1.8400	81.84	100	1.8697	89.14	48
1.8415	79.90	98	1.8590	87.51	46

1.3884	40.77	50			

Dr. Dalton prepared a similar table based on the boiling point, which in the strong acid gives a much greater range for a small difference in the percentage. The value may also be tested by neutralizing the acid with a standard alkaline solution. The density test is subject to error from the introduction and solution of foreign substances in the acid. Sulphuric acid has been recognized in a few instances in a native state; but its readiness to combine with bases must prevent its remaining free, except under peculiar circumstances, such as being received upon rocks like granite that are not acted upon by acids, or on others like gypsum already combined to saturation with sulphuric acid. Several instances are cited of its occurrence in caverns near volcanoes; and a river near the volcano of Parace in South America is called Vinegar river from the sour taste of its waters, due to the presence of sulphuric and hydrochloric acids.—The manufacture of sulphuric acid, as it is now carried on upon a large scale, is based upon the process of Dr. Roebuck, already referred to, of burning sulphur and nitre together in the presence of water. When sulphur is burned alone in air or oxygen, each atom of it combines with only 2 atoms of oxygen, forming sulphurous acid. To cause it to take up another atom of oxygen, the intervention of some third substance is necessary. Water alone produces this effect, but very slowly. The addition of a little deutoxide of nitrogen will cause this reaction to go on continuously in vessels supplied with atmospheric air and sulphurous acid. As this gas meets the air, it combines with 2 atoms of oxygen, forming the compound NO₂, as is seen in the red fumes that appear. A white crystalline deposit, formed of this substance, sulphurous acid, and water, is next produced on the walls of the vessel; and by the action of water its composition is suddenly broken up, deutoxide of nitrogen is reproduced by the 2 atoms of oxygen going to 2 atoms of sulphurous acid to convert these into sulphuric acid, and the deutoxide is set free to act again as a carrier of oxygen, and so on. In the large manufacturing operations the receivers are immense chambers of sheet lead supported by an outer framework of wood. This metal is selected as the most convenient material to use that is not acted upon by weak sulphuric acid. Some of the chambers are described as 140 feet long, 24½ wide, and 19½ high; and again 75 feet long, 40 wide, and 40 high; and of other similarly large dimensions; the object of the large size being to economize the proportional consumption of lead to the acid produced. The sheets selected for this use commonly weigh 5 lbs. to the square foot, and the edges are joined together by first scraping them perfectly clean, then laying them together as closely as possible, and melting them till they unite by means of the flame of the oxyhydrogen blowpipe. This is called autogenous soldering. Inside the chambers partitions or diaphragms of lead are

made across at intervals, leaving an opening alternately next the roof and floor, so that the vapors may be most thoroughly intermixed as they pass through the succession of compartments thus made. The floor of the chambers is covered 3 or 4 inches deep with water, which is gradually converted into acid in the course of the operation. The stove or furnace in which the sulphur is burned is a separate structure near the chamber with a flue connection; and there is also another small furnace near by provided with a boiler for furnishing steam, which by a late improvement is also discharged into the chamber and is carried along, serving to expedite the process by the thorough intermixture of aqueous vapor and gases and by keeping up the temperature to 100° F. or upward. The nitre is placed with some sulphuric acid in a cast iron pot in the sulphur furnace, elevated a little above the floor upon which this is burned. The fumes of nitrous and nitric acid pass on together with the sulphurous acid vapors, and are soon reduced in the chemical reactions to deutoxide of nitrogen. A draught is produced by a flue at the further extremity of the apparatus, opening into a tall chimney. But before entering this the vapors are made to pass through sulphuric acid contained in a condenser, by which any condensable products are arrested. Deutoxide of nitrogen and the nitrogen of the atmospheric air admitted through the furnace still pass on, and the former would be wholly lost but for the ingenious device of Gay-Lussac by which it is arrested and saved to be afterward returned to the chamber, thus reducing the consumption of nitre by more than one half of what it formerly was. This improvement consists in introducing the gases into a leaden tower filled with fragments of coke, through which a stream of concentrated sulphuric acid is continually trickling. This takes up the nitrous vapors and conveys them to a reservoir, whence the mixture is raised by the pressure of steam upon its surface into a cistern over the front of the first chamber. It is then discharged into the top of a small tower, and trickles down over a succession of sloping shelves, meeting a jet of sulphurous acid gas from the generating furnace, and is thence projected with this gas into the first chamber. This improvement also relieves the neighborhood from the noxious vapors that otherwise fall upon it from the chimney. In some of the French manufactories furnished with this arrangement, it is stated that not more than 8 lbs. of nitre are required to convert 100 lbs. of sulphur into 800 lbs. of acid. When the acid in the bottom of the chamber has attained a density of 1.35, or at most of 1.45, it is drawn off, to be employed for such purposes as acid of this strength is suitable for, or to be concentrated to higher degrees by other processes. If the operation were continued further in the chamber, the acid would absorb and permanently retain much nitrous acid gas. It is conveyed into large

rectangular pans of sheet lead, weighing 12 or 14 lbs. to the square foot, the edges of which are turned up so as to give them a depth of 8 or 10 inches. These are placed upon a grating of wrought iron bars, set very near together, over a fireplace, the flue of which is sometimes extended under other pans arranged in successive steps toward the chimney. In these the acid is evaporated by the heat of the flame beneath, and is gradually transferred by siphons from the upper to the lower pans, till in the lowest it has acquired a density of 1.65 to 1.75. To continue the process further in these pans would endanger the melting of their bottoms and the contamination of the acid by its taking up a portion of the lead. The product, known as the brown oil of vitriol, is used to considerable extent by bleachers, calico printers, dyers, &c. To raise it to the strength of concentrated oil of vitriol of commerce, it is necessary to make use of glass retorts or stills of platinum. The glass retorts are used of a much larger size than formerly, holding sometimes 20 gallons at the close of the rectification. They are set each one in an iron pot, the bottom of which is covered with a layer of dry sand. The concentration requires from 12 to 16 hours, and the vapors that distil over toward the last, carrying some acid with them, are condensed, to be returned to the lead pans. The process is known to be complete when the acid becomes clear by the removal of the coloring matter, which is only carried off at the highest point of concentration. The acid is then withdrawn through lead siphons, and is received into the glass 10-gallon carboys covered with straw, in which it is sent to market. Platinum stills are sometimes found to be more economical than glass retorts. They are made in Paris of various sizes, costing sometimes 80,000 francs each, and are used encased in cast iron pots, by which they are protected from direct action of the fire. One of the capacity of 70 to 80 gallons is capable of producing 80 carboys of rectified acid in 12 hours, one operation succeeding another without delay, while a glass retort is only used once in 20 hours. A platinum still may also be counted upon for 2 or 3 years' service, while a glass retort is liable to be broken by a current of air striking it when heated. The head of the still is formed of platinum also, and a platinum tube leads from it to a worm of lead which is kept immersed in water. During the operation the stream of concentrated acid is continually flowing. By a late improvement in the platinum manufacture, that metal is now alloyed with iridium, by which it is obtained in much stiffer sheets than when pure. When in use, the stills afford as the acid begins to boil a very weak distillate, which gradually increases in strength till it attains a density of 1.24, which indicates that the process has been carried to the highest practicable point of concentration. Dr. A. A. Hayes of Boston has adopted a process of crystallizing for

the same purpose. Acid of specific gravity 1.76, when cold, is treated while hot in the vessels of lead with a little nitre, which has the effect of oxidizing the organic impurities and rendering the acid clear. Sulphate of ammonia is then added to remove any excess of nitre or nitrous acid present, and the sulphuric acid, being concentrated to specific gravity 1.78 and drawn off into other deep vessels of lead, is cooled down to a temperature of 32°. When the acid is clear it is transferred to shallow lead vessels, in which by means of freezing mixtures it is reduced to the temperature of zero. When about half the bulk has crystallized, the mother liquor in which the impurities are concentrated is drawn off, leaving the pure crystalline acid, which may then be broken up, and, after being washed with pure acid of a former operation, be fused in a glass or porcelain vessel.—Sulphuric acid, as already stated, is also manufactured from iron pyrites. A great impulse was given to this branch of manufacture in England about the year 1835 on the occasion of the king of the Two Sicilies imposing a heavy duty upon the exportation of sulphur; and though this duty was afterward removed, the new processes then introduced were too firmly established to be broken up. In almost all countries pyritous iron and copper are abundant products; but it is rare that the sulphur they contain is saved. Reference has been made in COPPER SMELTING (vol. v. p. 691) to the enormous quantities of sulphur which are allowed to escape in the processes of reducing the copper ores at Swansea, South Wales. For burning pyrites a much higher heat is required than for burning sulphur, and the kilns employed for this purpose are constructed somewhat like a lime kiln in shape, with sides spreading upward. Some coke is generally mixed with the first charges to insure the ignition of the mass. In the first stage of the process but a limited amount of air is admitted through the small grate beneath, the combustion going on chiefly on the upper surface, where openings are made through the wall for admitting more air; but when the mass has attained a full red heat and the bisulphuret is converted by the loss of half its sulphur into the protosulphuret, the other openings are closed and all the air is passed through the ore to expel the remaining portion of sulphur. By this means the ore is prevented from becoming vitrified, in which condition its sulphur cannot be expelled. Nitrate of soda or of potash is placed in the flues through which the vapors pass, and affords the nitrous gas required. The remainder of the process is the same as that already described. Though the acid thus made almost always contains arsenic from the impurity of the ore, it answers very well the purposes of the manufacturer of soda from common salt, and of hydrochloric acid, which is to be used for making chloride of lime.—The Nordhausen or fuming sulphuric acid is the dihydrate named in the commencement of this

article. It is prepared at Nordhausen in Prussian Saxony and near Prague in Bohemia, for purposes requiring oil of vitriol of the highest degree of concentration, as for dissolving indigo in dyeing Saxony blue. One half the quantity answers that would be required of ordinary acid. It is produced from green vitriol derived from the residues after separating from iron pyrites a portion of the sulphur it contains. The vitriol, after being deprived of its water of crystallization by gentle heat, is distilled in small pear-shaped earthen retorts, great numbers of which are arranged in a horizontal position in a long furnace. The heat is gradually raised to an intense degree, and is so continued for several hours. A dark-colored dense fluid is collected in earthenware receivers, and is termed fuming from the white vapor of anhydrous sulphuric acid that escapes when it is exposed to the air. When these fumes disappear, the residue is ordinary oil of vitriol. By distilling the fuming acid in a glass retort, the white fumes of anhydrous sulphuric acid may be collected and condensed in a dry receiver surrounded with ice to a white crystalline body resembling asbestos. While dry this substance possesses no acid properties, and it may be moulded in the hands like wax without injury; but dropped into water it hisses as red-hot iron would do, and forms hydrated sulphuric acid.—Some of the uses of sulphuric acid have already been noticed. It is the acid in the large class of salts known as the sulphates, and is employed in the production of most of those which are artificially prepared, as alum and the sulphates of soda, potash, copper, and zinc. It is an important element in a great variety of chemical manufactures too numerous to be particularly named. In medicine it is sometimes used externally as a caustic, and diluted is administered internally for its tonic, antiseptic, and refrigerant properties. In low typhoid fevers and other inflammatory diseases, it acts to cool the system and restore strength, and in convalescence it excites the appetite and promotes digestion. It checks hæmorrhages and diarrhoeas not bilious, and colliquative sweats such as attend hectic fever. It is strongly recommended in choleraic diarrhoea, usually checking the vomiting, purging, and cramps after 8 or 4 doses of half a fluid drachm each, diluted with water, every 15 or 20 minutes. It is preferred to hydrochloric acid in calculous affections; is used in gargles for ulcerated sore throat; and is used internally and externally for many cutaneous diseases. The aromatic preparation called elixir of vitriol is the most agreeable form of administering sulphuric acid. It is a mixture of acid and alcohol with cinnamon and ginger.

SULPHURIC ETHER. See ETHER.

SULPHUROUS ACID, a gaseous compound of 1 equivalent of sulphur and 2 of oxygen (SO_2), a natural product sometimes issuing from fissures about volcanoes, and artificially produced whenever sulphur is burned. It is a

colorless gas of weak acid properties, a pungent suffocating odor, destructive to animal life, and extinguishing flame. Water takes up of it 40 to 50 times its bulk, and the mixture is gradually converted into sulphuric acid by absorbing oxygen from the air. Its weight compared with air being 2.247, it may be collected in dry bottles by displacement. If the gas as generated is passed through a tube surrounded by a freezing mixture, it is condensed into a transparent colorless liquid of specific gravity 1.42, which boils at 17.6°, and freezes at -105° into a colorless, transparent, crystalline solid. The liquid at common temperatures produces intense cold by its rapid evaporation. Sulphurous acid is a powerful deoxidizer, and is employed in chemical researches as a reagent for reducing various oxides to lower degrees of oxidation. The most important use of the acid in the arts is for the manufacture of sulphuric acid, as described in the preceding article. It is also largely employed for bleaching, especially straw hats and bonnets and articles of wool and silk. The goods are moistened with water and suspended in close chambers, in which the gas is produced by burning sulphur in open vessels. As it is absorbed by the goods, the colors disappear, but not through decomposition of the coloring matter as in the use of chlorine; for if the sulphurous acid be expelled by a stronger acid or neutralized by an alkali, the color may reappear. This is the case with new flannels when washed with soap. Sulphurous acid is also used for fumigating rooms, and as a bath in some cutaneous diseases. Its solution in water, from its property of arresting acetic fermentation, is used to rinse out beer barrels.—Sulphurous acid is prepared in a pure state by abstracting one atom of oxygen from sulphuric acid, which is done by boiling concentrated sulphuric acid with copper or mercury. The gas evolved is passed through a small quantity of water to free it from sulphuric acid, and then through a tube containing chloride of calcium to render it perfectly dry. It may be collected over mercury, or in dry open bottles. Charcoal or any dry woody fibre may be substituted for the copper or mercury; but the acid will in this case be mixed with carbonic acid, which however will not interfere with its use in the manufacture of alkaline sulphites.—Sulphurous acid unites with bases to form salts called sulphites; these are of little importance, excepting the sulphite of soda. (See SODA, vol. xiv. p. 769.) A mixed sulphite of lime and magnesia is manufactured to some extent to be used as a disinfectant; and the bisulphite of lime is employed in the manufacture of beet root sugar to prevent fermentation, and to decolor the juice or prevent its acquiring a color.

SULPICIAN, or **PRIESTS OF THE MISSION** or **St. SULPICE**, a congregation of priests in the Roman Catholic church, founded in 1641 by Jean Jacques Olier, for the purpose of educating pious priests. When in 1642 Olier became pastor of the parish of St. Sulpice in Paris, his

associates followed him and assisted him in the administration of his parish. Soon they became numerous, and were divided into two bodies, the one continuing to assist the pastor and living in common with him, the other taking the direction of a seminary which was established in an adjacent house. The seminary soon became so prosperous that the Sulpicians were called to a number of other dioceses, to take charge of the episcopal seminaries. At the time of the French revolution, they conducted in France 15 diocesan seminaries and 12 *petits séminaires* (preparatory schools), beside the 5 seminaries which they had in Paris. They had also one seminary at Montreal in Canada, and in 1789 founded one at Baltimore. During the revolution all their French houses perished; but by a decree of 1816 the congregation was restored, and soon resumed the control of a number of seminaries. In 1860 they conducted 19 seminaries in France and 2 in North America (Baltimore and Montreal), and numbered in all about 200 priests. Many of the members of this congregation, as the founder Olier, J. A. Emery, and Carrière, are counted among the greatest theologians of France.

SULPICIUS SEVERUS, a Roman ecclesiastical writer, born in Aquitania about A. D. 363, died in a monastery at Marseilles between 410 and 429. He was from a family of high rank, and in the practice of the law at Toulouse attained a great reputation for learning and eloquence, and led a gay though charitable life. The death of his wife led him to more serious pursuits, and having formed an intimacy with Martin, bishop of Tours, and Paulinus, bishop of Nola, he entered upon an ecclesiastical career, though it is not certain that he preached. His father disinherited him, but his mother-in-law gave him what pecuniary assistance he needed. Having entered a monastery, he spent some years in preparing an abridgment of the scriptural narrative, which from the purity of its style was long a favorite text book in the schools of the middle ages, but is liable to the charge of serious tampering with the facts, arising in part probably from the desire to rebuke in this guise some contemporary rulers. He continued this history, describing the destruction of Jerusalem, and bringing the narrative down to his own time, under the title of "The Chronicle of Sulpicius Severus," in which he varies materially from Josephus. His other works are: "Life of St. Martin, Bishop of Tours;" "Three Dialogues;" and a collection of letters. From the elegance of his Latinity he was called, not undeservedly, "the Christian Sallust." His works have been often printed; Jacob Bernays has republished his "Chronicle" with a commentary (Berlin, 1861).

SULTAN, a title applied to the chief rulers of most Mohammedan countries. It is derived from an Arabic word meaning a despotic ruler, or a man who is the arbiter of the life and property of men. The lawful wife of a sultan who has children by him is called a sultana.

SUMACH (Arab. *simac*), the common name of shrubs of the natural order of *anacardiaceae*, which likewise comprises lofty trees. The several species have a resinous or milky acrid juice; alternate, dotless leaves without stipules; small flowers imbricated in bud, either polygamous or pentandrous; their ovary 1-celled and 1-ovuled, the stigmas 8; the seed exalbuminous, borne on a curved stalk attached to the bottom of the cell; the fruit indehiscent and drupaceous. The order is represented in the old world by several tropical forms, such as the cashew nut, hog plum, mango, pistachio, &c.; but in the United States by the single genus *rhus*, the *povr* of Theophrastus, applied to the sumachs on account of the reddish color of their berries. One of the most prominent is the stag's horn sumach (*R. typhina*, Linn.), a tall shrub, sometimes attaining the appearance of a small tree, and even growing 25 feet high, with crooked irregular branches, its leaves pinnate, of many pairs, hairy beneath; the leaflets oblong, lanceolate, sharply serrate; the petioles and the younger branches covered with down like the young horns of a stag, which gives the trivial name to the species. In the autumn the leaves turn to a rich red color, tinted with yellow, orange, and purple. The flowers are dioecious, yellowish green, on a downy-stalked diffused panicle; the calyx short, hairy, with pointed erect segments; the petals of the same color, ovate concave; stamens 5, short, erect, with large anthers filled with orange pollen; in the fertile flowers the stamens are either wanting or else very minute; the stigmas 8, purple, crowning a hairy crimson germ; the fruit of a rich scarlet, turning purple and persistent all winter; the wood of a yellowish green color, brittle, soft, close-grained, and with abundant yellowish pith. The smooth sumach (*R. glabra*, Linn.) is a handsome, spreading, leafy bush, 4 to 10 feet high, with irregular branches; the leaves pointed, with smooth, somewhat glaucous leaflets, 11 to 31 in number, whitened beneath; the flowers greenish yellow. This species sometimes overruns barren and neglected fields, spreading rapidly by means of its long tough roots, and is difficult to exterminate. Its fruit possesses an agreeable acidity, and is variously employed in domestic economy. The acid is bimalate of lime, and exists in crystals of microscopic size among the down of the berries. The dwarf sumach (*R. copallina*, Linn.) is a shrub 1 to 7 feet high, with downy branches and footstalks; the leaves of 9 to 21 leaflets, smooth and shining above, slightly pubescent beneath, on winged-margined leafstalks; the flowers in a terminal panicle, the fertile flowers in smaller panicles; the fruit a compressed, short, ovoid drupe, of an agreeable acid taste. This species is especially beautiful on account of its polished foliage, which in autumn contrasts favorably in its purpling tints with the scarlet fruit. It is common on rocky hills and dry pastures. The *R. pumila* (Mx.) is a dwarf species with low procumbent stem, tomentose

branches, and leaves of 11 to 18 leaflets; it occurs on the pine barrens from North Carolina to Georgia. The tanners' sumach (*R. coriaria*, Linn.), a native of southern Europe, is a deciduous shrub, 10 to 15 feet high; its branches covered with a brown hairy bark; the leaves alternate and pinnate, of 7 to 8 pairs of leaflets and a terminal one; the flowers in large compound spikes at the end of the branches, of a whitish green color and appearing in July. It is extensively cultivated in Spain and Portugal for its young shoots, which are ground and employed in tanning, and is the kind used in the preparation of Turkey leather. The fragrant sumach (*R. aromatica*, Aiton) is a dwarf straggling bush found in dry rocky soil from Vermont westward and southward, with fragrant thick leaves of 3 rhombic ovate, unequally serrate leaflets, and pale yellow flowers projecting on short footstalks from angular, hairy-edged, brown, imbricated scales of aments, which grow from the axils of the last year's leaves. It is much cultivated abroad on account of its aromatic foliage. The *R. metopium* (Linn.) has dioecious flowers in loose panicles, oblong, smooth, scarlet drupe, chartaceous nut, arillate seeds, pinnate leaves, and a poisonous juice; it is a tree 15 to 20 feet high, and occurs in southern Florida. Other poisonous species met with at the south are represented likewise at the north in the *R. toxicodendron* (Linn.), known as poison oak and poison ivy (see Poison Ivy), and in the poison sumach or dogwood (*R. venenata*, De C.), a shrub 6 to 18 feet high, with nearly smooth branches, the stem light ashen gray, the young shoots purplish, the leaves pinnate on greenish purple petioles and consisting of 7 to 18 leaflets, and the flowers very small, green, in loose axillary panicles. The latter species was at one time confounded with the varnish-bearing sumach (*R. vernicifera*, De C., or *R. vernix*, Linn.); and according to Dr. Bigelow, a similar varnish can be prepared from its juice, the poisonous properties disappearing with the heat employed in boiling it down. The true kind is however a native of Japan and Nepal. Its leaves are very large and handsome, with 5 or 6 pairs of leaflets, all ovate, long, acuminate, entire, glabrous above and velvety beneath. The varnish is obtained from the juice of the younger branches. It is very hard, and is used extensively in the finish of every kind of woodwork by the Japanese.—The species of sumachs are numerous, and many are ornamental, those of the Cape of Good Hope being suited to the greenhouse and possessing evergreen foliage. For the open ground the Venetian sumach or smoke plant (*R. cotinus*, Linn.) is a conspicuous object in the garden. It is native to southern Europe, and though made use of in Italy under the name of *acotino* for tanning, yet it is mainly cultivated elsewhere for its beauty, growing under good treatment 10 or 12 feet high; its leaves are simple, obovate, smooth, stiff, shining green, supported on long petioles; the flowers are borne in very

large loose panicles of elongated hairy pedicels, each flower consisting of 5 small, oval, pale purplish petals; the first half cordate, smooth, veiny; the nut triangular. The fruit is however seldom seen, the pedicels, instead, lengthening indefinitely and producing a beautiful feathery appearance. It prefers a light loam, and is easily propagated by layers. An allied species, the *R. cotinoides* (Nuttall), occurs in the interior of Alabama, with perfect flowers in an open panicle, the pedicels mostly abortive, elongating, and plumose, the drupe smooth.—A species from Japan, the *R. succedaneum* (Willd.), has received some attention from an idea that a wax obtained from its fruit might be profitably employed. Both Kämpfer in the beginning of the last century and Thunberg in his "Travels" (1794), make mention of it. It is described as a shrub 10 to 15 feet high, similar to the varnish sumach, and bearing a berry or drupe, ovate, white, of the size of a cherry, enclosing a smooth nut; on boiling the berries the wax rises to the surface of the water in the form of a concrete volatile oil. It is used in making ornamental candles. According to Professor W. B. Rogers, the substance when cool has the whiteness and apparent purity of bleached beeswax, from which however it differs in various particulars, melting at about 127°, and parting with its fatty substances in alcohol at different temperatures; and Dr. O. T. Jackson found that after the alcohol has extracted all it can, a dry hard wax is likewise obtained by ether. The great readiness with which it is saponified, and the clear strong light it yields when burned in the form of candles, give promise that it may become an article of commercial importance; and especially so should the shrub prove itself adapted to the climate of the United States.—The sumachs possess various economical properties, several being employed in tanning; the bark of *R. glabra* is used as a mordant for red colors, and is considered a febrifuge; the fruit of *R. cotinus* is astringent, and its wood under the name of young fustic is used in dyeing a bright yellow color; the *R. metopium* yields a gum which has powerful emetic, purgative, and diuretic qualities; the root of the stag's horn sumach is administered in fevers; and the juice of the poison sumach stains linen an indelible brown. The several species propagate readily from seeds and from cuttings of the roots, and some deserve a place in ornamental plantations.

SUMAROKOFF, ALEXANDER PETROVITCH, a Russian dramatic poet, born in Moscow, Nov. 14, 1727, died there in 1790. He was educated in the land cadet corps, and began to write when 25. His plays were performed at court before the empress Elizabeth, and, encouraged by their success, he established a permanent theatre in the capital in 1756 under the direct patronage of the court. Though dramatic representations had been previously given in Russia, this was the first regular attempt to establish them, and Sumarokoff is considered

the founder of the Russian drama. His plays, all upon subjects drawn from Russian history, were published collectively with his other compositions in 1787 in 10 vols. 8vo.

SUMATRA, an island of the Indian archipelago, lying in a N. W. and S. E. direction along the S. part of the Malay peninsula, between lat. 5° 45' N. and 5° 55' S., and long. 95° 20' and 106° 5' E.; bounded N. by the bay of Bengal, N. E. by the strait of Malacca, the China sea, and the strait of Banca, E. by the Java sea, S. by the strait of Sunda, and S. W. by the Indian ocean; extreme length 950 m., breadth 250 m.; area about 160,000 sq. m.; pop. in 1857 estimated at 4,512,472. Part of the island is subject to the Dutch and part of it to native rulers dependent on that nation, while some portions are governed by independent princes. The Dutch possessions on the main island are divided into 4 governments, viz.: Sumatra (capital, Padang), on the W. coast, between lat. 0° and 1° 55' S., pop. 1,560,664; Bencoolen, on the same coast, S. of the former, pop. 114,460; Lampong, occupying the S. part of the island, pop. 85,525; and Palembang, on the E. coast, pop. 478,363; total pop., Dec. 31, 1859, 2,239,012. The islands of Banca and Rhio, off the coast, with several smaller islands attached to each, constitute separate Dutch governments. The independent states extend from lat. 2° S. on the N. E. coast round the N. end of the island as far as lat. 2° N. on the opposite side, and consist of Achcen, Batta, and some smaller states. A chain of islands stretches along the S. W. coast of Sumatra, parallel to and about 60 m. distant from the land, the most important of which are Hog island, lat. 2° 50' N., about 50 m. long by 10 broad, high and well wooded; Pulo Nias, the largest in the chain, also high and well wooded, and thickly inhabited; Pulo Mintao, about 48 m. long by 16 broad, the N. point of which is almost on the equator, and the S. part uninhabited; North Pora, about 80 m. long and 10 broad, separated by the Seaflovers channel from South Pora, about 36 m. long, both high and well wooded, and with several good harbors; the Nassau or North and South Pogy islands; and Engano, the southernmost of the chain, about 24 m. long by 18 broad, with inhabitants speaking a different language from that of the people of the other islands and of Sumatra. The Baniah islands lie in the strait which separates this chain from Sumatra, and are inhabited by people of the Malay race; the chief production is edible birds' nests. Beside the islands just described, there are numerous islands and shoals fronting the coast between Indrapoor and Tapanooly.—There are many good harbors on the S. W. coast of Sumatra, that of Tapanooly being considered one of the finest in the world. The whole of this coast is exposed to a very heavy surf, and more especially that portion which lies S. of the equator. About 150 m. of the N. coast, between Achcen and Diamond point, is called

the coast of Pedir; it is high and bold, and the anchorage is mostly in open roadsteads. The N. E. coast is low, and toward the narrowest part of the strait of Malacca the shore becomes faced with sand and mud banks, and the navigation intricate and dangerous. The island of Rupat, lat. $2^{\circ} 10' N.$, which extends about 25 m. each way, is separated from Sumatra by a narrow strait, only navigable by small vessels. Between lat. $1^{\circ} 36'$ and $0^{\circ} 35' N.$ are 8 large islands, called Bacalisse, Pedang, and Rankan, with a navigable strait from 1 to 5 m. broad between them and Sumatra. The coasts of these islands, and also of Sumatra as far as the E. side of the strait of Sunda, are exceedingly low, fronted by mud banks, and part of the land inundated at high tide.—There are many rivers on the S. W. coast, but they have all short courses and are very rapid. Upon the opposite side of the island there are some large rivers, the chief of which are the Rawas, or Palembang, which falls into the strait of Banca, and is navigable for 200 m.; the Jambi, Indragiri, Campore, Sumpar, and Singkel. In the lower part of their courses these rivers are very sluggish, and they all have extensive deltas at their mouths. There are several lakes in the mountain valleys toward the W. side of Sumatra, the best known of which are Sinkara, Dano, and Daho, the last named said to lie at an elevation of 4,000 feet above the sea. The S. W. coast is bold and mountainous, with high cliffs rising in many places from the ocean. Parallel to the coast 3 or 4 chains of mountains, varying from 2,000 to 5,000 feet in height, with peaks of still greater altitude, run the whole length of the island. These mountains are clothed with forests of luxuriant growth, and for about 350 m. the breadth of level ground between the shore and the mountain forest is not more than 2 m. Toward the N. end of the island this tract increases to about 8 m., and in a few places it has a width of from 15 to 20 m. Along these chains are about 20 volcanoes, some of which rise much higher than the general mountain mass. The country lying upon the N. E. coast is not much elevated above the sea, but toward the interior the ground rises and forms plains of great extent, while that enclosed between the mountain ridges to the W. is an elevated table land with a hilly broken surface. Basalt, granite, trachyte, syenite, red sandstone, and limestone are all found in Sumatra. Iron ore, copper, and tin are abundant, and gold is collected in many of the streams, but principally in the Jambi and Indragiri and their tributaries. Petroleum, sulphur, and steatite are also found.—The climate of Sumatra is warm and moist, the thermometer ranging throughout the year between 76° and 93° , and rain falling almost incessantly, more particularly in the S. In the neighborhood of the marshes it is very unhealthy, but in the elevated districts and upon the S. W. coast it is said to be favorable to longevity. The soil is remarkable for its fertility, but the

greater part of the island has been very imperfectly explored. Much of the E. coast is covered with mangrove bushes. Further inland are found palms, and trees of gigantic growth, few of them being less than 100 feet in height. On the W. shore, beside the myrtle and several varieties of fig, all the fruit trees common to the archipelago abound, and most of the mountains are covered to their summits with jungle. The *Rafflesia*, a parasitic flower found adorning the trees of the forests, is a yard in diameter, and has a calyx capable of containing 6 quarts. Rice is extensively cultivated. The cocoanut, betelnut, sago tree, capsicum, pepper, turmeric, ginger, coriander, &c., are all grown. Camphor and benzoin are found in the forests in the N. part of the island; and caoutchouc, or the India rubber tree, abounds. Elephants are numerous in the forests; tigers of great size and ferocity are common. The buffalo exists both wild and domesticated. The horses are small, and generally piebald. The boa constrictor sometimes grows to an immense size.—The inhabitants of Sumatra are of the Malay race, of which the island is supposed to have been the cradle. They are divided into several tribes, who speak languages that are considered as dialects of one common tongue. Beside those of Malay origin, there are two nations who live in the woods in a savage state and have little intercourse with the others. They are called the Orang Kubu and the Orang Gugu, and their origin is involved in obscurity. The people of the N. part of Sumatra about Acheen are taller, stouter, and of darker complexion than the other tribes, and are supposed to have a considerable infusion of Hindoo blood. The Bataks or Battas, who occupy the country immediately S. of these people, are smaller and of lighter complexion, and in some respects a very singular race. (See BATAK.) Mohamadanism is the prevailing religion, but it is in a relaxed state, and the people of the interior cannot be said to belong to any particular faith. These tribes have a religious system of their own, and their priests exercise great authority over them. The Malays round the coast appear to be collected from different parts of the archipelago, and many Chinese have settled about the S. end of Sumatra. The ordinary dress is a turban and loose trowsers reaching to the knee; the upper part of the body is commonly uncovered in both sexes, but a scarf is sometimes worn about the shoulders. The houses are raised on posts or pillars from 4 to 8 feet from the ground, and in some parts of the country they are erected in trees. Those of the poorer classes are made of bamboo and thatched with grass, but the houses of the more wealthy are generally framed of wood and the sides enclosed by large sheets of bark. Agriculture is in a very rude state. The labors of the field are for the most part carried on by the women. Polygamy is not common, except among the chiefs, who have sometimes

6 or 8 wives each. The inhabitants have arrived at a considerable degree of perfection in the manufacture of iron and steel, and the kreeso or dagger blades made in Sumatra are highly esteemed. Many kinds of tools, silk cloth, and earthenware are made; and the gold and silver filigree work is much admired. The trade of Sumatra is principally carried on with Java, Madura, Singapore, Malacca, Penang, and British India. The chief exports are pepper, gold dust, camphor, nutmegs, cloves, mace, benzoin, gutta percha, copper, tin, sulphur, and coral. In 1854 there arrived in the principal ports of Sumatra, from Java and Madura alone, 964 vessels of an aggregate of 44,446 tons.—The Malay name of Sumatra is Pula Percha, and the island was first called Sumatra by Niccolò di Conti, who visited it before 1449; Marco Polo calls it Java Minor. In 1509 the Portuguese first reached the country. They arrived on the N. coast, and found the territory around Acheen ruled by a powerful king, who effectually opposed their obtaining a footing. Internal discord shortly afterward reduced the power of the kingdom to insignificance. The Dutch arrived on the N. coast about the close of the 16th century, and the English soon afterward made their appearance. The former nation formed a settlement at Padang in 1649, and the latter at Bencoolen in 1685. The Dutch got possession of some districts in the S. part of the island and established several factories. In 1811 their settlements on Sumatra, together with the island of Java, were taken by the British, but were restored in 1816. In 1824 the British exchanged Bencoolen for Malacca and small settlements upon the coasts of Hindostan. By fomenting internal feuds, and taking the side of a number of petty chiefs, the Dutch have since found means to annex a great extent of territory.—See "History of Sumatra," by W. Marsden (4to., 8d ed., London, 1811).

SUMBAWA, or SOEMBWA, an island of the Indian archipelago, in the Sunda chain, lying between Floris on the E. and Lomboe on the W., the S. W. point situated in lat. $9^{\circ} 2' S.$, long. $116^{\circ} 42' E.$; length E. and W. 160 m., extreme breadth 50 m.; pop. about 80,000. The coasts are very much indented by arms of the sea, and lined by several small islands. It is divided into 6 native states, each governed by a rajah who acknowledges the supremacy of the Dutch. Of these states Tomboro and Sumbawa are on the N. coast, Bima on the E., where the Dutch have a resident, and Dampo, Sangar, and Papakat on the other parts of the island. The surface is mountainous, and many of the summits have a very remarkable appearance. The most singular of these is Tomboro, a volcano near the N. coast, 8,940 feet high, which had a dreadful eruption in 1815, the noise of which was heard over an area with a radius of more than 800 m. Many thousand people were killed; the ashes fell in Java to the depth of several inches, and even in Sumatra at the distance of 840 m.

from the volcano. In 1886 another eruption occurred, but less destructive. Gold is found, and the most valuable mineral products are sulphur and saltpetre. Sandal and sapan wood and teak are all found, but the last is not very abundant. There are two breeds of horses, one of which is the best in the Indian archipelago, and is extensively exported. The pearl oyster is found. The manners and language of the natives bear a strong resemblance to those of the inhabitants of Celebes. The island has been subject to the Dutch since 1676.

SUMMER, the warm season of the year, including astronomically the time between the vernal and autumnal equinoxes, or from about the 21st of June till about the 22d of September. As one of the four seasons into which the year is popularly divided, the summer comprises in the United States the months of June, July, and August; in England, May, June, and July.—The Indian summer is a period of warm, pleasant weather, which usually occurs every year over the northern portion of the United States after the autumnal storms, and continues often without interruption 2 or 3 weeks, when it is succeeded by the cold weather and storms of the winter. It appears to be a more decided season in the interior than near the coast, and in the region of the great lakes is especially noticeable, the waters during its continuance remaining placid, in marked contrast to their disturbed condition in the earlier part of the autumn, the weather mild and pleasant, and the atmosphere filled with a peculiar haziness. At this time the woods are in their brightest colors, the leaves before their fall assuming the brilliant autumnal hues peculiar to the American climate. It is a fine season to navigate the lakes, and is usually looked for in that region during the first portion of November. Further east it appears to be somewhat earlier. It is especially recognized by the prevailing hazy atmosphere and gentle S. W. breezes. It was a favorite season with the aborigines, and is hence called Indian summer. They regarded it, as stated by the Rev. James Freeman, as the gift of their most honored deity, the god of the south-west, who sends the S. W. winds, and to whom they believed their souls to go after their decease.

SUMMERFIELD, JOHN, an American clergyman, born in Preston, England, Jan. 31, 1798, died in New York, June 18, 1825. He was educated at a Moravian school, was destined by his father for the Methodist ministry, and exhibited great precocity of intellect, but early fell into irregular habits, which at one time brought him into prison at Liverpool. In 1813 his father removed to Dublin, where at the age of 19 the son joined the Wesleyan society. In 1819 he was received on trial as a preacher in the Irish conference, and in 1821 removed with his father to America, and was received as a preacher in the New York conference. Such was his peculiar and chastened eloquence that persons of all

denominations, and of all classes and professions in society, flocked in crowds to hear him, and his services were sought for on all popular religious occasions. In 1829 he visited Philadelphia, Baltimore, and Washington; but his constitution, naturally feeble, gave way under his excessive labors, and for the purpose of recruiting his health he sailed in December for France. While in Paris he attended the anniversary of the French Protestant Bible society as a representative of the American Bible society, for which he prepared an address which was published in French. After spending some time in England, he returned to New York in April, 1824, with little change in his health; but he continued to travel and preach whenever possible, with undiminished success. Shortly before his death he aided in founding the American tract society. A volume of his "Sermons and Sketches of Sermons" has been published (8vo., New York), and a biography by John Holland (8vo., New York, 1829).

SUMMERS, THOMAS OSWORN, D.D., an American clergyman, born near Corfe Castle, Dorsetshire, England, Oct. 11, 1812. In his 18th year he came to the United States, joined the Methodist Episcopal church in 1832, began to preach in 1834, and was admitted into the Baltimore conference in March, 1835. His first appointment was to the Augusta circuit, in Virginia, on which he had to travel 250 miles and preach 30 sermons a month. In 1840 the bishop appointed him to the republic of Texas; and he was one of the 9 preachers who constituted the first Texas conference, which was organized in Dec. 1840. In 1844 he became a member of the Alabama conference. He was secretary of the convention at Louisville, Ky., at which the M. E. church, South, was organized, and at the general conference of 1846 was appointed assistant editor of the "Southern Christian Advocate," and also chairman of the committee to compile the new hymn book, the labor of which principally devolved upon him. In 1850 he was elected by the general conference its editor of books and tracts, and of the "Sunday School Visitor," and in 1858 also of its "Quarterly Review." He has been secretary of every general conference. Beside numerous tracts and pamphlets, and introductions, notes, &c., to various works, he has written "A Treatise on Baptism" and "A Treatise on Holiness;" the "Sunday School Teacher, or the Catechetical Office;" "Seasons, Months, and Days;" "Talks Pleasant and Profitable;" "The Golden Censer;" "Scripture Catechism," in 2 vols. (Old and New Testaments); and "Questions on Genesis."

SUMMIT. I. A N. E. co. of Ohio, drained by the Cuyahoga and the head streams of the Tuscarawas river; area, 400 sq. m.; pop. in 1860, 27,340. It is the most elevated land on the line of the Ohio canal, and hence the name. The surface is uneven, and the soil highly fertile. The productions in 1850 were 825,642 bushels of wheat; 365,762 of Indian corn, 225,998 of

oats, 237,538 of rye, 100,898 of potatoes, 37,793 tons of hay, 1,927,351 lbs. of butter, and 268,971 of wool. There were 4 newspapers, 83 churches, and 9,614 pupils attending public schools. Bituminous coal and mineral paint are found in abundance, and exported largely. There is an ample supply of water power. The Cleveland and Pittsburg and the Cleveland, Zanesville, and Cincinnati railroads, and the Ohio canal traverse the county. Capital, Akron. II. A new co. in Utah territory; pop. in 1860, 198.

SUMNER, a N. co. of Tennessee, bordering on Kentucky, bounded S. by the Cumberland river, and drained by affluents of Big Barren river; area, 600 sq. m.; pop. in 1860, 22,030, of whom 7,700 were slaves. The surface is undulating and the soil fertile. The productions in 1850 were 1,875,590 bushels of Indian corn, 209,077 of oats, 38,874 of wheat, 809,517 lbs. of tobacco, and 197,213 of butter. There were 21 churches, and 1,542 pupils attending public schools. It is intersected by the Louisville and Nashville railroad. Capital, Gallatin.

SUMNER, CHARLES, an American statesman, born in Boston, Mass., Jan. 6, 1811. His father, who died in 1839, was a lawyer by profession, and during the latter part of his life was sheriff of the county of Suffolk. The son received his early education at the Boston Latin school, and was graduated at Harvard college in 1830. He continued in private the studies of college life for a year, and then entered the law school at Cambridge, where he formed with his teacher, Judge Story, an intimate friendship which continued till the death of that eminent jurist. He was admitted to the bar in 1834, and soon attained a larger share of practice than any other lawyer in Boston so young in the profession. He was appointed reporter of the circuit court of the United States, in which capacity he published 3 volumes known as "Sumner's Reports," containing decisions of Judge Story. He also at the same time edited the "American Jurist," a quarterly law journal of high reputation. During the first 8 winters after his admission to the bar, while Judge Story was absent in Washington, Mr. Sumner was appointed lecturer to the law students, and part of the time, during the absence of Prof. Greenleaf, he had sole charge of the school. His favorite topics were those relating to constitutional law and the law of nations. In 1836 he was offered a professorship in the law school, and also one in the college, both of which he declined. In 1837 he visited Europe, where he remained till 1840, travelling in Italy, Germany, and France, and residing for nearly a year in England. On his return to Boston he resumed practice, and in 1844-'6 published an elaborate edition with annotations of "Vesey's Reports" in 20 vols. Though voting with the whig party, he took no active part in politics till 1845, when on the 4th of July he pronounced before the municipal authorities of Boston an oration

on "The True Grandeur of Nations," in which, prompted by the menacing aspect of affairs between the United States and Mexico, he denounced the war system as the ordeal by battle still unwisely continued by international law as the arbiter of justice between nations, and insisted that this system ought to give way to peaceful arbitration for the adjudication of international questions, as the private ordeal of battle had given way to such substitutes in the administration of justice between individuals. His oration attracted unusual attention, led to much controversy, and was widely circulated both in America and Europe. It was pronounced by Richard Cobden to be "the most noble contribution made by any modern writer to the cause of peace." It was followed by a rapid succession of public addresses on kindred themes before literary and academic societies and popular assemblies, which were also widely circulated in print. Mr. Sumner earnestly engaged in the opposition to the annexation of Texas on the ground of slavery, and at a popular meeting in Faneuil hall, Nov. 4, 1845, made a speech against that measure which was warmly applauded. In the following year he made an address to the whig state convention of Massachusetts on "The Anti-Slavery Duties of the Whig Party," and shortly afterward published a letter of rebuke to Mr. Robert C. Winthrop, who then represented Boston in congress, for his vote in favor of the war with Mexico. These steps led eventually to Mr. Sumner's separation from the whig party and association with the free-soilers, to whose candidates, Van Buren and Adams, he lent efficient support in the presidential contest of 1848. After the withdrawal of Mr. Webster from the senate of the United States by his entrance into the cabinet of Mr. Fillmore in 1850, Mr. Sumner was nominated for the vacancy by a coalition of free-soilers and democrats in the Massachusetts legislature, and was elected after a most earnest and protracted contest, which attracted the universal attention of the country, and the termination of which was publicly celebrated in many places by the anti-slavery party. His first important speech was upon the fugitive slave act, against which he argued that congress had no power under the constitution to legislate for the rendition of fugitive slaves; and that if it had, the act in many essential particulars conflicted with the constitution, and was also cruel and tyrannical. In this speech Mr. Sumner laid down as a guide for political action the formula to which he has since adhered, that "freedom is national and slavery sectional." In the debate on the repeal of the Missouri compromise and on the contest in Kansas, Mr. Sumner took a very prominent part. His last speech upon this topic, which was subsequently printed under the title of "The Crime against Kansas," occupied two days in its delivery, May 19 and 20, 1856. Some passages in it greatly incensed the members of congress from South Carolina, one

of whom, Preston S. Brooks, on May 22 assaulted Mr. Sumner while writing at his desk in the senate chamber, and with a gutta serena cane struck him on the head till he fell to the floor insensible. (See Brooks, Preston S.) The injury thus received proved very serious, and was followed by a severe and long disability, from which his recovery was not complete till 8 or 4 years later. His term of office as senator expired March 4, 1857, and in the preceding January the legislature of Massachusetts had re-elected him by a unanimous vote in the senate, while in the house of representatives, consisting of several hundred members, he received all but 7 votes. Under the advice of physicians he went to Europe for the benefit of his health in March, 1857, and returned in the autumn to resume his seat in the senate. His health being still impaired, he went abroad again in May, 1858, and submitted to a course of extraordinarily severe medical treatment in Paris, which did not terminate till the autumn of 1859, when he again returned home. His first serious effort after the restoration of his health was an elaborate speech in the senate, denouncing the influence of slavery on character, society, and civilization, which was subsequently printed under the title of "The Barbarism of Slavery." In the presidential contest of 1860 he took an active part, and made several speeches in behalf of Abraham Lincoln and Hannibal Hamlin, the successful candidates. In the senate, during the discussions resulting from the secession of the slave states, he earnestly opposed all concession to or compromise with slavery, and early proposed emancipation as the speediest mode of bringing the war to a close. He also urged the same policy in popular addresses at Worcester, Mass., Oct. 1, and New York, Nov. 27, 1861. In these and in his other efforts against slavery, he has based his arguments not only on moral and historical, but on constitutional grounds, and has always claimed that the positions he has taken and the measures he has advocated are in strict accordance with the constitution of the United States. Since March 4, 1861, he has been chairman of the senate committee on foreign relations, and on Jan. 9, 1862, delivered an elaborate speech arguing that the seizure of Messrs. Mason and Slidell on board the steamer Trent was unjustifiable on the principles of international law which had always been maintained by the United States. Mr. Sumner is the author of a work on "White Slavery in the Barbary States," expanded from a lecture (12mo., Boston, 1853); and two collections of his addresses have been published: "Orations and Speeches" (2 vols. 12mo., Boston, 1850), and "Recent Speeches and Addresses" (12mo., Boston, 1856).

SUMNER, INCREASE, an American statesman and judge, born in Roxbury, Mass., Nov. 27, 1746, died there, June 7, 1799. He was graduated at Harvard college in 1767, and afterward took charge of the grammar school at Roxbury,

and at the same time studied law in the office of Samuel Quincy. He was admitted to the bar in 1770, and in 1776 was elected a member of the state legislature, where he continued to hold a seat till 1782. He was also a member of the convention held in 1777 "for agreeing on a form of government," and of that of 1779 for forming a state constitution. In 1782 he was elected by the legislature a member of congress, but did not take his seat in that body, having in the same year been appointed an associate judge of the supreme judicial court. In 1797 he was elected governor, and reelected in 1798 and 1799 with remarkable unanimity. His intimate relations with the leading statesmen, and especially with his kinsman John Adams, then president, enabled him to exercise much influence in public affairs.

SUMNER, JOHN BIRD, 90th archbishop of Canterbury, and primate of all England, born at Kenilworth, Warwickshire, in 1780. He was educated at Eton, and at King's college, Cambridge, and in 1820 was appointed canon of Durham, and in 1828 bishop of Chester, in which capacity he gave a remarkable impulse to the establishment of churches and infant schools. In 1848 he was translated to the archbishopric of Canterbury. He is a liberal in politics, and is considered the leader of the low church or evangelical portion of the Anglican establishment. He is the author of an essay on "Apostolical Preaching;" "The Records of Creation," which obtained the 2d Burnett prize of £400; "Evidences of Christianity;" "Exposition of the Acts of the Apostles;" "Chester Charges;" and of several volumes of sermons.

SUMTER. I. An E. district of S. C., bounded W. by the Wateree and Santee rivers, and S. by the Santee, and drained by Black river and its affluents; area, about 1,500 sq. m.; pop. in 1860, 23,860, of whom 16,682 were slaves. The surface is generally undulating and the soil fertile, and there are extensive forests of pine. The productions in 1850 were 750,520 bushels of Indian corn, 7,410 of wheat, 44,465 of oats, 876,555 of sweet potatoes, and 18,779 bales of cotton. There were 87 grist mills, 7 saw mills, 8 tanneries, 1 cotton gin factory, 62 churches, 2 newspaper offices, and 504 pupils attending public schools. It has water communication by the Santee river, and is intersected by the Wilmington and Manchester railroad. Capital, Sumterville. II. A S. W. co. of Ga., bounded E. by Flint river, and intersected by Muckalee and Kinchafoonee creeks; area, 590 sq. m.; pop. in 1860, 9,428, of whom 4,890 were slaves. The surface is level and the soil fertile. The productions in 1850 were 854,842 bushels of Indian corn, 120,383 of sweet potatoes, and 7,535 bales of cotton. There were 25 churches, and 265 pupils attending public schools. Capital, Americus, to which there is a branch railroad from Macon. III. A central co. of Fla., bounded W. by the Withlacoochee river; area, about 400 sq. m.;

pop. in 1860, 1,549, of whom 549 were slaves. The surface is generally level and swampy, and there are several small lakes, the principal of which are Lakes Eustis, Griffin, and Yala. Capital, Adamsville. IV. A W. co. of Ala., bordering on Miss., bounded E. by the Tombigbee, and intersected by the Noxubee river; area, about 800 sq. m.; pop. in 1860, 24,085, of whom 18,091 were slaves. The surface is uneven and the soil fertile. The productions in 1850 were 926,826 bushels of Indian corn, 62,359 of oats, 182,007 of sweet potatoes, and 14,066 bales of cotton. There were 37 churches, 2 newspaper offices, and 438 pupils in public schools. It has water communication by the Tombigbee river, and is intersected by the proposed route of the Alabama and Mississippi railroad. Capital, Livingston.

SUMTER, FORT, a work at the entrance of Charleston harbor, S. C., built upon an artificial island, and situated about $2\frac{1}{2}$ m. from Castle Pinckney, the fort at the point of the peninsula on which Charleston is situated, and nearly the same distance from Fort Moultrie. It is a fort of the 2d class in size; its foundations are of stone, and the walls from the water line up, 50 feet high, of brick, filled in with concrete. It was several years in building, and cost nearly \$1,000,000. Its form is that of a truncated pentagon, with one side parallel to the adjacent shore and presenting an angle to the channel. Of the truncated angles, those on the E., W., and N. are simply formed into *pans coupés*, while the other 2 are each composed of 2 small faces, making an angle of about 15° with the side of the pentagon, and having a sally port at the intersection of their faces. It was intended to mount 140 guns upon the fort, in 3 tiers, the upper *en barbette*, the 2 lower in casemates. Of these guns 80 were to be 64-pounders, 30 32-pounders, 40 24-pounders, 10 8-inch and 10 10-inch columbiads, and 10 13-inch and 10 10-inch mortars. The fort was as yet unfinished, and but few of the guns were mounted, when on Dec. 26, 1860, Major Robert Anderson removed his garrison by night from Fort Moultrie to Fort Sumter. The garrison consisted of about 70 soldiers, with 80 or 40 workmen. This removal was construed by South Carolina, which had 6 days before published her secession ordinance, as an act of war, and the surrender of the fort demanded from the U. S. government, but not conceded. Meantime Major Anderson exerted himself with his little force to put the fort in a condition of defence, by mounting what guns he could, raising and revetting the parapet, &c. He was able to mount but 53 guns in all, 27 on the ramparts and 25 in casemates, and but few of these his heaviest guns. The South Carolina authorities erected batteries and strengthened those already erected, so as to place the fort under $\frac{1}{4}$ of a circle of fire, and many of their guns were of very heavy caliber. Supplies were also cut off, and the garrison reduced almost to a state of starvation. Unsuccessful at-

tempts were made by the U. S. government to furnish supplies or reinforcements to the fort, and about midnight of April 11 its instant surrender was demanded by Gen. Beauregard, the commander of the beleaguering forces. Major Anderson, whose provisions were exhausted, answered that unless he received relief he would capitulate on the 15th; but the order for surrender was repeated peremptorily and refused, and before 4 A. M. the bombardment commenced. The garrison replied through that day and till noon of the next, when their cartridges were nearly exhausted, and, the barracks and woodwork having been set on fire by the shells from the batteries, preventing access to the magazine, their fire slackened. Mr. Wigfall, acting as aid to Gen. Beauregard, came to the fort with a flag of truce, and himself hoisted upon it a white flag; and Major Anderson and the garrison marched out with the honors of war, first saluting the U. S. flag with 50 guns. The bombardment of this fort was the first act of the war between the U. S. government and the seceded states.

SUMTER, THOMAS, an American revolutionary general, born in South Carolina about 1784, died near Statesburg, S. C., June 1, 1882. Little is known of his history previous to the opening of the revolutionary war, when he appears as lieutenant-colonel of a regiment of South Carolina riflemen. After the capture of Charleston by the British in 1780, he took the field as a brigadier-general at the head of a body of light horse, and soon became one of the most active and able partisan leaders of the South. His bravery, endurance, and unvarying cheerfulness and determination under reverses gained him from his followers the sobriquet of the "Carolina game cock" and Cornwallis confessed that he was one of his "greatest plagues." After gaining important successes over the British and Tories, he was, in Sept. 1780, routed with considerable loss near the mouth of Fishing creek on the Oatawba by Tarleton. By great exertions he soon collected another corps of light troops, and on Nov. 8 defeated Col. Wemyss, who had attacked his camp in Chester district near Broad river. Twelve days later Tarleton attempted to surprise him while encamped at Blackstocks on the Tiger river, but was compelled to retreat with severe loss, leaving his wounded to the mercy of the victor. Sumter, having been severely wounded in this encounter, retired for a while into North Carolina; but in Feb. 1781, he again took the field with undiminished activity, and, in concert with Marion, Pickens, and other partisan chiefs, carried on a harassing warfare against the enemy's scattered posts in the low country. He subsequently participated with credit in the battle of Eutaw Springs, but was soon after compelled by ill health to retire from active service. In Jan. 1781, congress passed a complimentary resolution of thanks to him and his men. He was afterward for several years a member of congress from South

Carolina, and in 1809 was appointed minister to Brazil, where he remained two years. Upon his return he was elected a U. S. senator from South Carolina. The latter years of his life were passed in retirement.

SUN, the central body of the planetary system, and the great source of light and heat. It is a globe of 888,842 m. in diameter, or nearly 8.7 times the distance of the moon from the earth. Its mean distance is 95,808,650 m. according to the determinations made at the last transit of Venus in 1769, though this estimate has not the perfect confidence of astronomers. A second of angular measurement at the earth corresponds to 461 m. of the sun's surface. Its volume is 1,415,925 times that of the earth, though its density being only .2548 the density of the earth, its weight is no more than 854,986 times that of our planet. Gravity at its surface is 27.9 times what it is at the earth; that is to say, a body weighing 100 lbs. here would weigh on the surface of the sun 2,790 lbs. It has an apparent motion among the stars from west to east along a great circle called the ecliptic (see ASTRONOMY, and ECLIPSE), making a complete circuit of the heavens in 365 days, 6 hours, and 9 minutes, though the period from midsummer to midsummer is some 20 minutes less, owing to the precession of the equinoxes. (See PRECESSION.) This motion is not uniform, due in part to the obliquity of the ecliptic, and in part to the eccentricity of the same; it is greatest about Dec. 31, when it amounts to $1^{\circ} 1' 9.9''$ daily, and least about July 1, when it is $0^{\circ} 57' 11.5''$. It has also 3 true motions: 1, an axial rotation, which it performs in 25d. 8h. 9m., the axis being inclined to the plane of the ecliptic $7^{\circ} 9'$; 2, a sort of orbital motion around the centre of inertia of itself and its system of planets, but in consequence of the great superiority of its mass over the aggregate mass of all the other bodies of the system, this centre of inertia is always within the sun's volume; 3, a progressive movement through space, in the direction of the constellation Hercules, and at the rate of 154,185,000 m. a year. Like the moon, it undergoes a slight alteration in apparent diameter in consequence of its apparent orbit being elliptical. It reaches its maximum diameter of $32' 35.6''$, and its minimum diameter of $31' 31''$, simultaneously with its greatest and least apparent velocity, these two variations being due to the same cause.—Solar eclipses vary in number from 2 to 5 every year. They are called total, annular, or partial, according to the amount of the sun's disk covered by the superposed moon. An annular or ring eclipse can only happen when the apparent diameter of the sun is greater than that of the moon. A total eclipse of the sun is not accompanied by utter darkness, the degree of light being different for different places of observation. In the great eclipse of 1860, as observed in Spain, the photograph yielded results which showed a greater degree of light than is afforded by the full moon, and

yet elsewhere in the track of the shadow the darkness was so great that thermometers could not be read. This light proceeds from a halo which encircles the disk of the moon at such junctures.—When the sun is examined through a telescope, its surface is found to be marked by black spots edged with a penumbral fringe of uniform shade; they appear sometimes singly, sometimes in groups. These spots are not permanent, but undergo changes of form from day to day, or even from hour to hour, indicating a gaseous form of matter. They seldom last longer than 6 weeks, and often only a few hours. They are seen to break out and enlarge, or to contract and disappear; and occasionally one is observed to divide into several. When they disappear, the black centre, or nucleus, always vanishes before the penumbra. Mr. Dawes, an English observer, has noticed a violent whirling going on in some of the spots. Father Secchi, of the Roman college, describes one as presenting a filamentous aspect, the filaments seeming like currents and appearing to describe spiral curves. Their size is sometimes enormous. Mayer records having seen one in 1758 whose diameter was $\frac{1}{10}$ that of the sun; and Secchi thinks some spots are deeper than the earth's radius. They are not scattered promiscuously over the surface of the sun, but are almost entirely confined to a belt of 25° on either side of the equator, the northern being much the favorite hemisphere. The zone of 8° N. and 8° S. of the equator is nearly barren of spots. This distribution suggests the idea that they may be connected somehow with the rotation of the sun; and Sir John Herschel infers the existence of a movement in the solar atmosphere analogous to our trade winds. According to Laugier, they seem to have a motion of approach toward the nearest pole; and these motions are strikingly correspondent on opposite sides of the equator, a fact which lends confirmation to Herschel's supposition. Often, just before disappearing, the spots undergo remarkable changes. Ridges of light are seen to dart across the chasm, splitting it into many parts, and these have been known to separate from each other and dart along in new and disturbed paths. Here again is suggested an analogy to our trade winds. Schwabe, of Dessau, by a most persevering study of the spots for upward of a third of a century, during which he has recorded the number visible on each day for nearly 800 days in every year, arrived at a remarkable law of periodicity affecting them. They are found to gradually increase in number up to a certain period, and then to decrease to a certain period, and then to increase again, and so on. The cycle is completed, according to this investigator, in 10 years. Prof. Wolff, of Zürich, has, by collating the ancient observations, deduced a period of 11.11+ years as the length of the cycle. (See *MAGNETISM, TERRESTRIAL*.) Sabine, Lamont, and Gautier have arrived at similar results independently. In the *Comptes rendus* for Jan.

1859, Prof. Wolff presents a formula according to which the abundance of the spots is determined by the position of the 4 planets, Jupiter, Saturn, Venus, and the earth. Beside the spots, the telescope reveals minute dark dots or pores mottling the surface, and these are found to be in constant fluctuation. Sir John Herschel compares their appearance to the slow subsidence of some flocculent chemical precipitates in a transparent fluid when viewed perpendicularly from above. Near the great spots or groups of spots there are often seen streaks more luminous than the neighboring surface, called *faculae*. They are oftentimes seen toward the borders of the disk. Mr. Dawes saw, on Oct. 22, 1859, in a large mass of faculae, one bright streak forming the very edge of the sun, and projecting irregularly beyond the circular contour, reminding him of a ridge of low hills often seen at the enlightened limb of the moon. M. Ohacornac, a most diligent French investigator, observed on one occasion a sudden transformation of the luminous part of the photosphere into dark parts; luminous bridges were seen crossing the spots, and then gradually becoming dark. As these luminous bridges darkened, they at the same time plunged into the deeper parts, and became covered with other luminous bridges which formed above them. Whether any or all these remarkable changes going on in the surface of the sun have any thing to do with the climate of the earth, as some maintain, remains for the future investigator to determine.—The spots were among the earliest discoveries of the telescope. They were seen about the same time by Galileo, Scheiner, Fabricius (who was the first to publish an account of them), and Harriot; and it was by watching them that these early observers determined the rotation of the sun and the approximate period of the same, and inferred the existence of a solid, dark nucleus enveloped by a luminous atmosphere. In China they appear to have been observed as early as A. D. 321. There is no account extant, however, of any careful series of observations upon them till 1769, when Dr. Alexander Wilson, of Glasgow, turned his attention to them. He distinguished the dark nucleus and its penumbral fringe, and noticed that one side of the latter became gradually narrower as the spot approached the central line of the solar disk, and that the opposite side became at the same time gradually wider. To account for this phenomenon, he supposed the dark nucleus to be, as Galileo and his contemporaries had hinted, a portion of the opaque surface of the sun exposed to view through a funnel-shaped opening in a luminous atmosphere, and the penumbra to be the side walls of the funnel seen in the general direction of the axis of the opening. A similar view was held independently by Bode, of Berlin, a few years later. Beside the luminous envelope, Wilson suspected the presence of a second and less luminous covering within the other. In 1779 Sir William Herschel investigated the

subject, and adopted and brought forward in a clear exposition the theory of Wilson.—Up to 1851 the state of our knowledge respecting the remarkable phenomena presented at total eclipses of the sun was very unsatisfactory. A plan of observations was organized for observing the eclipse of that year with a view to establishing the true character of the phenomena; and now at every favorable recurrence of total eclipses of the sun elaborate preparations are made on every side for observing it. There is seen, first of all, during total obscuration, a corona of white light encircling the black disk of the moon like the glory round a saint's head in pictures; secondly, in this corona, and jutting out from the margin of the moon or separated altogether from it, are seen, often with the unassisted eye, flame-like objects of various colors and forms. The corona is marked, in various parts of its circumference, by long outlying streamers of light. These, according to the united testimony of Secchi, De la Rue, Foucault, and Von Feilitzsch, who watched the phenomenon in the eclipse of 1860, are most perceptible where the colored forms appear. It is the opinion of some, Leverrier and Foucault among the number, that the corona does not belong to the solar atmosphere. The latter considers it an example of the "interference of light" (see DIFFRACTION), the phenomenon being held to be analogous to the colored fringes seen on a screen in a darkened chamber when a solar beam is admitted through a chink in the wall. To this theory Prof. Airy raises the objection that if, in order to make the assumed analogy perfect, the eye be placed in the position of the screen, no colored fringes are seen. It is shown that the corona has the property of polarization, and hence is composed of reflected light. Prazmowski has further proved that the plane of polarization passes through the sun, the corona, and the observer. All this, in the judgment of Prof. Airy, points strongly toward the existence of an atmospheric medium, capable of reflecting light, extending from the earth to the moon. The colored forms, or prominences, have long been objects of great interest to astronomers. They were noticed as early as 1706 by Capt. Strannyan at Bern, and more distinctly by Vassénus at Gothenburg in the total eclipse of May 3, 1723. The early observers took them to be solar mountains, but their magnitude, as referred to the sun, makes this incredible. M. Petit, director of the Toulouse observatory, estimated one he saw in 1860 to be at least 60,000 m. in thickness and 240,000 m. in height, on the supposition of a solar origin. Their forms are somewhat irregular, and at first imperfectly defined, though presently assuming an approximately pyramidal outline. They are sometimes isolated, but commonly project from the edge of the disk nearly perpendicularly, and sometimes toward the extremity bend away at nearly a right angle, just as a vertical column of smoke when it strikes an upper current

is drifted off horizontally. Goldschmidt describes having seen, in 1860, half a minute before totality, little gray clouds floating in the corona at some distance beyond the edge of the moon. In an instant the clouds became clear and rose-colored as a pyramidal prominence. At the same eclipse Secchi also saw fine red clouds entirely detached from the borders of the moon. It is noticed that, as the moon moves across the solar disk from right to left, the prominences on the left side shorten and those on the right side lengthen. Otto Struve, in 1860, made careful measurements of these changes, and found that they agreed completely with the rate of the moon's motion. This points to a solar origin of the prominences. If they belonged to the moon, they must have moved along with her, as the eclipse progressed, without alteration. It has been asserted that they correspond in position with the spots, and many observers have inferred accordingly that the two are somehow connected, either as cause and effect, or as common effects of some prior force. But the assumption is unfounded; it is proved that no connection of position exists between them. To explain the prominences, Arago suggested a third envelope, above the photosphere, composed of feebly luminous clouds; and this hypothesis, which accounts for the corona as well, has been very generally adopted. Leverrier, on the other hand, assumes the existence of a kind of roseate matter covering the solid nucleus of the sun, which last he believes to be in a state of incandescence; the spots themselves he supposes to be casual accumulations of this rose-colored matter, and elevations rather than depressions. Lamont of Munich supposes them to be due to vaporous clouds in our own atmosphere, formed by condensation within the cone of the ecliptic shadow. (See "London Philosophical Magazine," June, 1860.) During the brief interval of totality at any one station there is no perceptible change in the form of the protuberances, except as the advancing lunar disk covers or uncovers a portion of their length. But in comparing the drawings made by observers in 1860 on the W. coast of America with those made by observers in Spain, there being a difference of some two hours between the two observations, irreconcilable differences were found in the appearances of the prominences. This fact, allowing that the drawings were in each case accurate, points to the probability that the prominences, if they belong to the sun, as is generally admitted, are of such a nature as to be subject to rapid alterations of form. They are found to be unpolarized, and therefore are not seen by reflected light. It has been thought they might be seen at other times than during eclipses; but Prof. Piazzi Smyth failed to detect them from his lofty observatory on the peak of Teneriffe in 1856. This was to be expected, however, from the high atmospheric illumination through which we necessarily view

the sun.—A curious phenomenon known as "Baily's beads," from the observer who first called attention to them, has been repeatedly noticed at total eclipses of the sun, and has puzzled astronomers not a little. It occurs at the instant before and the instant after totality, and consists in an apparent breaking up of the thin visible margin of the sun into bright spots interrupted by black spaces, like a string of beads. The late Prof. Baden Powell thought that the phenomenon arises from viewing the sun's edge between the mountains of the moon with bad telescopes or telescopes out of focus, and partly from the nervous excitement of the eye. In this opinion Prof. Airy, who declares that he has never been able to see the phenomenon, coincides.—Recent experiments with the spectrum indicate the presence in the sun's atmosphere of familiar elements. Fraunhofer had discovered in the solar spectrum a series of dark lines known as "Fraunhofer's lines." Brewster had discovered that a peculiar light could be produced if the rays passing through the prism had first to traverse certain gases. More recently Bunsen had discovered that if, in the flame of a lamp employed to produce the spectrum, the slightest portion of any metal or other element was introduced, there would then appear in the spectrum a different set of lines, having a different color or characteristic for every element; the $\frac{1}{1000000}$ part of chloride of sodium could be detected by this means. Applying this elegant mode of qualitative analysis, Kirschhof has discovered in the atmosphere of the sun several metals, including sodium, calcium, lithium, iron, &c., which can only exist there in the gaseous state.—How to account for the supply of the prodigious amount of heat constantly radiated from the solar surface offers a boundless field of hypothesis. One theory is that the sun is now giving off the heat imparted to it at its creation, and that it is gradually cooling down; another ascribes it to combustion; a third to currents of electricity; a fourth to the compression of matter from the nebulous state, the condensation going on continually without altering the weight of the body, or affecting necessarily the volume of the enveloping photosphere. (See NEBULAR HYPOTHESIS.) Newton and Buffon conjectured that comets might be the aliment of the sun; and now a somewhat similar theory is much in vogue, viz., that a stream of meteoric matter, constantly pouring into the sun from regions of space very near it, supplies the fuel for the evolution of its heat. This theory was first broached by Mr. Waterston in England in 1858. It appears from careful measurements of Secchi that the different portions of the solar disk, contrary to the opinion of Arago, do not radiate heat in uniform degrees. His tables show that the equatorial regions are twice as hot as the polar. M. Fizeau has proved that the same diminution subsists for chemical radiation. The same is found to be true for the intensity of the sun's light.

M. Chacornac has proved that, while the central part of the disk has a uniform brightness for a distance from the centre of about $\frac{1}{3}$ of the radius, the light then diminishes, and the brightness of the centre surpasses that of a point about one half the radius from the centre, by $\frac{1}{10}$ of itself. Mr. De la Rue has succeeded in taking a photograph of the sun, 3 feet in diameter, which exhibits the shading off of the solar light toward the edge of the disk. From a long course of experiments instituted by Prof. Piazzi Smyth, with thermometers buried in the earth's surface at various depths, there resulted an indication of periodical waves of solar heat distributed over a secular swell, whose period is so long that only a small portion of it appears in the time of 17 years. These observations point to the suspicion that the sun belongs to the class of variable stars.—To sum up briefly the best received hypothesis of the physical constitution of the sun: It is a solid body surrounded by 8 atmospheric strata. The first of these is an elastic medium bearing a dense bed of vaporous clouds. On the top of this floats a luminous stratum or photosphere, composed of unconnected phosphoric clouds, and subject to continual fluctuations both from local causes of agitation and from the subjacent vapor acting by its elasticity to burst through the photosphere above it, thus producing the appearance seen as spots in the disk; the facule, which are found to be above the general level of the photosphere, are taken to be heapings up of the luminous masses like the crested surges of the sea; this stratum is several thousand miles in thickness. Over all is a third envelope, of imperfect transparency and of great depth, containing in a vaporous condition iron, sodium, lithium, and various other metals. These strata are subject to great movements, which sometimes have the character of uniform progression analogous to our trade winds, and sometimes are violent and resemble in their effects our tornadoes and whirlwinds.

SUN BIRD, the name commonly given to the *promeropidae*, a family of tenuirostral birds, with a long, slender, and usually curved bill, the nostrils placed at the base and covered with a scale, wings of moderate size, and short tarsi covered with broad scales. They are very brilliant birds, inhabiting the tropical regions of both hemispheres; the sub-family *promeropina*, including by far the most species, is confined to the old world, and the *carebina* to the new. The true sun birds belong to the former, and have a long, slender, curved, and sharp bill, sometimes finely serrated on the margins; the tail is long, the central feathers often exceeding the rest. They are found in the islands of the Pacific and Indian oceans, and on the continents of Africa and Asia; they are the humming birds of the old world, having similar habits and the same brilliant colors, but are of larger size; in morning and evening great numbers are seen hovering and quarrelling over flowers, into which they thrust their

long bills in search of insects, spiders, and honeyed juices; the song is said to be agreeable; the natives use the beautiful feathers as ornaments. The genus *nectarinia* (Illig.) contains more than 100 species, mostly African; the nest is usually suspended from a twig, of an elegant form, with an opening on the side protected from the sun and rain by a projecting portico; it is frequently strengthened and covered with spiders' web; the eggs are 2 to 4. For figures and descriptions of some of the most beautiful species, see "Sun Birds" and "Birds of West Africa" in Jardine's "Naturalist's Library." The *carebina* or gaitgaita have a shorter, broader, and nearly straight bill, and long pointed wings; they are found in tropical South America and the West Indies, having the same habits as the last sub-family; the plumage is very beautiful, but has not the metallic brilliancy of the humming and sun birds. The nests are often suspended from the ends of twigs, with the entrance on the under side, protected by a long funnel or by 2 compartments, in which the young are secure against insects, other birds, serpents, and lizards.

SUN FISH, the common name of the fishes of the diodon family and genus *orthogoriscus* (Schn.). The skeleton is soft and only partially ossified; the body short and round, compressed laterally; the skin rough, covered with mucus, but without spines; jaws undivided in the middle, forming a cutting edge; mouth small, the teeth adapted for bruising sea weeds and soft-bodied animals; the body is truncated posteriorly, looking as if it had been cut off at the dorsal and anal fins and then furnished with a short broad caudal; there are no ventrals, no air bladder, and no abdominal sac capable of distention; the dorsal and the anal fins are more or less united to the caudal; the stomach is small, and immediately receives the biliary canal. The common sun fish (*O. mola*, Schn.) is almost circular in form, and the dorsal and anal project posteriorly, with the caudal between; on each side, near the centre, is a small pectoral, and in front of it the gill opening; the gills are arranged in comb-like fringes; it is also called moon fish and head fish. It attains a large size, 4 or 5 feet in length and 3 or 4 in depth, with a weight of several hundred pounds; the flesh is white, tough, of a disagreeable odor, unfit for food, and remarkably elastic, the last property depending on the great amount of yellow elastic fibre, interlaced in an intricate manner, almost to the exclusion of white fibre and true muscle. It is grayish above and whitish below, with a silvery lustre when alive, and phosphorescent at night, which, with the rounded form, has given rise to the popular name. It is sluggish in its motions, and is often seen asleep at the surface on both sides of the Atlantic; when swimming, it is said to turn round like a wheel, and to be able to float with the head and eyes above the surface; the liver is very fat, and its oil is used for lubricating purposes on board ship, and for

sprains and bruises among fishermen. In some seasons it is common in summer in Massachusetts and New York bays, and feeds partly if not principally on medusæ or jelly fishes. There is probably no fish more infested by parasites, internally and externally; the flesh and intestines contain many entozoa, and the skin is studded with crustacean parasites of the genus *pen-nella*, to which are usually attached numbers of the cirriped *cineras vittata*, and to both many polyp stems; crustacean fish lice (*cecropis Latreilli*) are also generally found, and other parasites on the skin and gills.—The name of sun fish is also commonly given to many medusæ. (See JELLY FISH.)

SUNBURY, the capital of Northumberland co., Penn., on the E. bank of the Susquehanna river, 56 m. N. from Harrisburg, and 184 m. N. W. from Philadelphia; pop. in 1860, 2,200. It has 5 newspapers, a number of churches, and several manufactories and machine shops. The Philadelphia and Erie, the northern central, and Shamokin railroads connect at this place; and the Shamokin dam, 2,783 feet long, just below the town, connects it with the canal on the opposite side of the river. About 150,000 tons of anthracite coal, from the Shamokin region, are shipped from Sunbury every year.

SUNDA ISLANDS, a term formerly applied to the islands of the Indian archipelago which lie around the Java sea, sometimes called the Sunda sea. These islands were divided into the greater and the lesser Sunda islands, the former of which included Java, Borneo, Sumatra, and Celebes, and the latter the chain of islands which extends from the E. extremity of Java to New Guinea.

SUNDA STRAIT, an arm of the sea between the islands of Sumatra and Java, which leads from the Indian ocean to the Java sea. The length of the channel upon the Sumatra side, from Flat point, in lat. 5° 59' S., to Hog point, is about 65 m.; and upon the opposite coast, from Java Head, lat. 6° 47' S., to Bantam point, about 85 m. The breadth of the strait where it joins the Indian ocean is about 60 m., and at the end next the Java sea about 20 m.

SUNDAY (Sax. *Sunnan dag*), the first day of the week, identical with the Roman *dies Solis* (day of the sun). Among Christian nations it is kept as a sabbath, and in remembrance of the Saviour's resurrection. In the early ages of our era the day was devoted as far as practicable to religious worship, which began at daybreak; and as early as the end of the 2d century abstinence from worldly business appears to have been customary. When the Christian religion came to be recognized by the state, laws were enacted for the observance of this day. Constantine ordered in 321 the suspension of all business in the courts of law except the manumission of slaves, and all other business except agricultural labor. Additions were made to this order under various emperors, and in 425, under Theodosius II., games and theatrical exhibitions were forbidden. In

588 the third council of Orleans forbade all labor on Sunday. Many theologians maintain that there is no divine authority for any distinction between Sunday and other days. (See *LORD'S DAY*.)

SUNDAY SCHOOLS. From the first organization of Christian churches, the custom prevailed of assembling the children and youth, and those who, though professedly receiving Christianity, were not as yet fully instructed in its doctrines, on the first day of the week, for Christian instruction. The persons thus taught were called catechumens. The "Church and House Book" of the early Christians, as collected by the chevalier Bunsen ("Christianity and Mankind," vol. ii.), gives special directions regarding these catechumens, specifying who were to be received and who rejected, the length of time (3 years) they were to be taught, and the instruction which was to be communicated to them. These catechumens were all expected, after instruction, to receive baptism and become members of the church. During the 4th and succeeding centuries, at least to the 8th, religious instruction was given, at first on the first day of the week, but subsequently on other days, to the children and youth, in the porches of the churches. This custom was eventually given up, and though occasional efforts were made to revive it they were not permanently successful. There is no record of the subsequent establishment of any such schools until 1527, when Martin Luther organized several in Germany. These were not however intended for catechumens, but "for the instruction of children and youth who could not attend the day schools in the art of reading, that they might thereby be better able to read the Holy Scriptures." In the latter half of the 16th century Cardinal Borromeo organized Sunday schools, first in the cathedral of Milan, and subsequently throughout his diocese. In these schools reading and writing were taught, and some religious instruction was bestowed. In the 17th century catechetical instruction of the children was practised in a few parishes of England by the clergymen, and in 1674 also in a church in Roxbury, Mass.; and several schools were established for secular instruction of those who could not obtain the rudiments of education through the week. De la Salle established a number in Paris, and they were also organized in Rome, Vienna, and other cities. At these schools instruction was given in reading, penmanship, arithmetic, drawing, and sometimes even in higher branches. Some of these schools, or others of a like character, are still maintained in the continental cities. Many others were established in the 18th century, but no idea of any thing but local organizations seems to have been entertained until the time of Raikes toward the close of the century (see *RAIKES, ROBERT*), and for two years his efforts were confined to the vicious street children of Gloucester, whom he had been led to collect into schools from having been personally an-

noyed by their tumultuous and profane conduct. In Nov. 1788, he first published in his own newspaper, the "Gloucester Journal," the results of his efforts, and recommended the extension of Sunday schools throughout the country. His narrative was copied into other newspapers, and schools were very soon established in all the principal towns. In 1785 William Fox, a merchant of London, who had been for some time engaged in the promotion of week day schools for the instruction of the children of the poor in the Scriptures, becoming acquainted with Raikes's plans, determined to substitute Sunday for week day schools for this purpose, and reported a plan of organization for the "Society for promoting Sunday Schools in the British Dominions." In 1786 it was estimated that 250,000 children were receiving Sunday school instruction in Great Britain. The same year Bishop Asbury of Virginia established the first Sunday school on Raikes's plan in the United States. In 1791 the First day or Sunday school society was established in Philadelphia, Bishop White being its president. Sunday schools were organized in Ireland in 1798, and in Scotland in 1797. In the latter year Samuel Slater established a Sunday school in Pawtucket, R. I., for his operatives. A poor African woman, Katy Ferguson, knowing nothing of Raikes or of Sunday schools elsewhere, established the first in New York city in 1798, for the benefit of the poor street children of the humble quarter in which she lived. It is said that a school for secular instruction on Sunday was organized in New York in 1791, and incorporated in 1796, but it contemplated no religious instruction. Between 1801 and 1804 Mrs. Isabella Graham and her daughter, Mrs. Joanna Bethune, who had become familiar with the English Sunday schools while travelling in Europe, established 8 of these schools in New York at their own expense. From that time they gradually increased in the United States, but the first in connection with a church was at Pittsburg, Penn., in 1809. By 1815 they had extended to most of the countries of Europe and to Ceylon and Australia.—The Sunday school, as instituted by Raikes and his successors, was a very different thing from the Sunday schools of the present day. The teachers were hired; the pupils were for the most part only the very ignorant and often vicious children of the pauper classes; very few of them could read, and the spelling book and hymn book were the principal text books required. Some religious instruction was given, but not in the way of scriptural lessons, as these would not have been understood. The library, as an adjunct to instruction, was not yet introduced. The change from paid to voluntary teachers, and from secular to religious instruction, was made in the United States about 1809, and was simultaneous with the transfer of the control of the schools from individuals to churches. This change took place at a much later period in Great Britain. The

system of rewards, by the gift of little books, or in some schools of tickets, a certain number of which entitled the holder to a small money reward, was a common inducement to attendance and study. After the Sunday school society founded in 1785, the next organization for the promotion of Sunday schools was the London Sunday school union, founded in 1803. The Hibernian Sunday school society was founded in 1809, the New York Sunday school union in 1816, and the American Sunday school union in 1824. The objects of this last institution were twofold: the providing suitable text books, primers, question books, picture cards, and a collection of unexceptionable volumes for libraries; and the establishment of Sunday schools, by the agency of missionaries, in the more recently settled regions of the country. Its publications for the first 2 or 3 years were confined mostly to periodicals, spelling books, tickets, reward books, hymns, alphabetical cards, and the like. The Sunday school union led the way in substituting a lending library, attached to each school, for the gift of books; and in 1849 it had published 700 bound volumes of library books, and about as many more question books, alphabetic cards, tickets, maps, and other appliances of instruction. Its catalogue for 1861 gives the titles of nearly 2,000 books, of which 1,003 are suitable for libraries, and its annual expenditure is about \$390,000. There have also been organized 6 or 7 denominational Sunday school unions or societies, all of them publishing Sunday school books, and some nearly or quite as largely as the American union. Three tract societies have also issued numerous books intended for these libraries, and 8 or 10 private publishing houses have engaged in the same business. The reprints of English Sunday school books are often issued simultaneously by several of these publishers; but aside from these, the number of distinct works written for Sunday school libraries, published in the United States, is not less than 4,500. The whole number of children attending Sunday schools in the United States in 1861 was estimated to be considerably above 3,000,000. Since 1848 special attention has been given to the establishment of mission Sunday schools, gathering for religious instruction the vagrant and vicious children of the streets of the larger cities into comfortable school rooms, for elementary religious instruction, giving them at the same time food or some articles of clothing. These schools are sustained either by particular churches, by young men's Christian associations, or by city missionary or Sunday school societies. Libraries and the other appliances for instruction are furnished for these, and the teachers who volunteer to instruct them are usually well qualified for their work. The establishment of town, county, and state associations for Sunday school teachers, with frequent meetings for consultation, has greatly improved the character of the instruction in these schools. In Great Britain,

Sunday schools have of late years attained to a great degree of efficiency. In England the dissenters, and especially the Methodists, have labored zealously in their promotion, and all classes have aided in the establishment of the mission or ragged Sunday schools. The Wesleyan Sunday schools in Great Britain in 1860 had 494,489 pupils, and the Primitive Methodist schools 180,064. The whole number of children in attendance upon Sunday schools in Great Britain and Ireland in 1861 was about 3,600,000, and of teachers not far from 840,000. The number of different works published by the societies for Sunday schools was over 5,300. In Ireland, the total number of schools reported in 1860 was 2,705, of scholars 283,390, and of teachers 21,302.—In France the Sunday school has never prospered. Some of the Protestant churches have schools, and the efforts of the deaconesses of Strasbourg and Paris have been exerted with considerable success for their organization; but, except for the secular instruction of artisans and others who have no opportunity of study during the week, there are few or none of them in connection with the Catholic churches. In Germany and the Scandinavian countries, under the vigorous efforts of Dr. Wichern and the members of the inner mission, they have within a few years past been extensively established. Italy, though claiming in the person of Borromeo to have been the original home of the institution, has very few Sunday schools, and those few mainly in Sardinia or the states which have been longest annexed to it.

SUNDERBUNDS, a marshy tract of British India, in the Bengal presidency, stretching across the lower part of the delta of the Ganges, between the bay of Bengal and the inhabited parts of the delta, from the river Hoogly to the island of Rabanabad, 158 m., with a breadth of about 75 m.; area, 6,500 sq. m.; pop. very small. The soil is alluvial, and the whole district is cut up into innumerable islands by rivers and creeks, many of them navigable for vessels of considerable size. The woods swarm with tigers and other tropical animals. Salt is manufactured from the sea water to a sufficient extent to supply the demand of the lower provinces of Bengal.

SUNDERLAND, a seaport town and parliamentary borough of Durham, England, situated at the mouth of the river Wear in the North sea, 12 m. N. E. from the city of Durham and 268 m. N. by W. from London; pop. in 1861, 80,324. The parliamentary borough includes the townships of Sunderland, Bishop Wearmouth, Bishop Wearmouth Pans, Monk Wearmouth, and Monk Wearmouth Shore. The Wear passes through the borough, and is crossed by an iron bridge, high enough for large sailing vessels to pass underneath, which connects Monk Wearmouth with the S. side of the river. The harbor is formed by the mouth of the river, and is protected by piers at the sides extending into the sea, that on the N. being 1,000

feet and that on the S. 1,800 feet in length. The docks upon the S. side of the river have an independent entrance to the sea. Ship building is extensively carried on, amounting in seasons of ordinary prosperity to 60,000 or 70,000 tons. On Jan. 1, 1860, 1,004 vessels of 282,261 tons belonged to the port. In 1859 there were cleared from Sunderland 10,786 vessels, tonnage 1,712,928; and during the same year 2,633,232 tons of coal were exported. The chief manufactures consist of earthenware and glass, anchors, chains, canvas, and all kinds of articles required for fitting out vessels. Nearly 7,000 tons of window glass and 23,000,000 glass bottles are annually manufactured. Sunderland has 4 railway termini which connect with different lines, and afford facilities for intercourse with all parts of Great Britain. The borough returns 2 members to parliament.

SUNDERLAND, ROBERT SPENCER, second earl of, an English statesman, born about 1641, died at Althorp, Sept. 28, 1702. After serving as ambassador to Spain and France, he became in 1679 secretary of state, and engaged in political intrigues, at first opposing and afterward favoring the exclusion bill. In 1681 he went out of office, but was recalled in 1682, and exercised a controlling influence in the administration during the remainder of the reign of Charles II. Under James II. he retained his place as secretary, in 1685 was made president of the council in addition, and in 1687 became a Roman Catholic, much to the delight of King James. Seeing, however, the signs of a coming revolution, he carried on a secret intrigue with the prince of Orange; and in Oct. 1688, he was dismissed by James. On the arrival of the prince of Orange, Sunderland went to Rotterdam, where he was thrown into prison, but was released by order of William. He then went to Amsterdam, again turned Protestant, and after a short residence at Utrecht returned to England, although excluded in the act of indemnity. For some months he led a secluded life, but was thenceforth constantly employed by William III., although at first holding no office. On April 19, 1697, he was appointed lord chamberlain, but on Dec. 25 following suddenly resigned, and spent the remainder of his life at Althorp. During a large portion of his life Sunderland's income from his various offices, from bribery, and from the selling of places, was enormous. He never made any public speeches, his ascendancy being due to his insinuating manners and cunning.—**CHARLES SPENCER**, third earl of, an English minister, son of the preceding, born in 1674, died April 19, 1722. Professing republican principles, he entered the house of commons in 1695 as member for Tiverton, and occupied that position in the 3 succeeding parliaments. In 1705 he was sent to Vienna as envoy extraordinary and plenipotentiary, and in 1707 became secretary of state, from which post he was dismissed in 1710. He was generally regarded as the head of the whig party, and on the acces-

sion of George I. he was made lord lieutenant of Ireland, in 1715 lord privy seal, and in April, 1717, secretary of state. In 1720 he introduced Walpole and Townshend into the cabinet. On the investigation of the matters connected with the South sea scheme by the house of commons, Sunderland was implicated in the criminal transactions charged upon the directors; through the influence of Walpole he was acquitted by a vote of 233 to 172, but was obliged to give up office. He still, however, had great influence with the king, and during the remainder of his life was busily engaged in intrigues to effect the downfall of Walpole. By his marriage with the second daughter of the great duke he became progenitor of the present house of Marlborough, their son succeeding as second duke. His magnificent library is preserved at Blenheim.

SUNFLOWER, the common name of a popular annual originating in South America, but long known in cultivation. The same name is applied to several other species having perennial roots, and found indigenous to other parts of the world. Structurally considered, the blossoms of the sunflower are series of many florets inserted upon a slightly convex receptacle or disk, the outer series only having ligulate, petal-like, expanded segments, by which arrangement the flower heads assume a stellar appearance of great size. In the annual sunflower (*helianthus annuus*, Linn.) the terminal flower head is sometimes very large and broad, and presents a bold and showy character, corresponding to the stout, strong, branching stem, and the coarse, cordate, 3-nerved leaves. Usually the color of the florets is a deep orange yellow, though sometimes it is of a pleasing pale sulphur tint. When the entire surface of the disk is covered with ligulate florets, the variety is called double by gardeners. The annual sunflower is only partially admitted into flower gardens, unless where some particular effect is needed by planting it in masses for a background or in isolated clumps. It has been however strongly recommended as a field crop to be employed for economical purposes. The soil most proper for its growth is of a light friable nature, abounding in alkali; but it is considered as peculiarly exhaustive, and in analyses of its leaves and stems large proportions of potash are found. The seeds (*achenes*) contain a great quantity of oil fit for burning in lamps, and nearly as good as olive oil for domestic uses or for the manufacture of soap. Meal and bread are said to be made of them in Portugal; and they are roasted as a substitute for coffee. They are likewise eagerly sought for and eaten by several species of birds, and are recommended for the fattening of poultry. The tuberous sunflower or Jerusalem artichoke (*H. tuberosus*, Linn.) has a slenderer stem, which is round and hairy, and its leaves are rough, long, tapering at base into narrow, wedge-shaped petioles; the flower heads are numerous, and the achenes rather compressed, 4-sided,

and wedge-shaped. (See *ARTIOHOKA*.) A dwarf perennial species (*H. multiflorus*), with cordate-ovate, 3-nerved leaves, has been long in cultivation in the flower garden, and serves as a conspicuous object in the hotter and drier summer months, the double variety being mostly seen. The roots require only a slight protection in winter. It has been supposed to be a native of North America, but later investigations have thrown doubt upon the statement. The number of species indigenous to the United States, according to Torrey and Gray, is about 40, and these are geographically distributed from the Atlantic states to the Pacific ocean. On the western prairies the annual growth of stems of some species attains to the height of 15 feet. The sunflowers are usually to be found in dry soils, in woods and on rocky places, from New England and New York westward; and 21 species are cited by Ohapman as distributed throughout the southern states.

SUNFLOWER, a N. W. co. of Mississippi, bounded E. by the Yazoo and intersected by the Sunflower river; area, about 1,000 sq. m.; pop. in 1860, 5,019, of whom 3,917 were slaves. The surface is level and swampy, and the soil highly fertile. The productions in 1850 were 33,390 bushels of Indian corn and 1,900 bales of cotton. The Yazoo river is navigable for steamboats during most of the year. Capital, McNutt.

SUNNA, and **SUNNITES**. See **SOONNA**.

SUNSTROKE. In warm climates, exposure to intense heat, particularly while the body is exhausted by labor, marching, &c., is a fertile source of disease and death. In severe cases the person falls insensible; he is unable to speak or to swallow; the countenance is commonly dark-colored and injected, the breathing slow and labored, the pulse slow or very small and frequent. Death may occur at the end of a few hours. When the patient recovers, he often remains for a long time feeble, and suffers from headache, confusion of thought, and loss of memory. When death takes place, post-mortem examination shows great congestion of the brain, lungs, and heart.—It was formerly customary to bleed freely in cases of sunstroke, but the results of the practice were by no means satisfactory. Some years ago it was ascertained that all the cases of sunstroke brought into the New York hospital, that had been bled, proved fatal. Cold applications to the head, frictions to the limbs, a mustard plaster to the epigastrium, and, when the patient can swallow, the internal administration of stimulants, is the treatment that affords the most satisfactory results.

SUNSTROKE, INDIAN. See **CALENTURE**.

SUPERCARGO, a person who accompanies a cargo shipped to a foreign port, and is intrusted with the sale of it there, either as specially directed or to the best advantage, and with the investment of its proceeds in a proper cargo for the home or other market. As the supercargo's authority properly concerns the cargo,

it is ordinarily dormant during the voyage, and is called into exercise by arrival at the foreign port; and though for the sake of the cargo and a market the supercargo may sometimes have the authority to determine the destination of the ship, yet he has none to interfere in the navigation of her, or in any respect to usurp the office and functions of the master. The powers and duties of a supercargo are not very specifically regulated by law or usage, but are determined in every instance by the express instructions of the shipper where such instructions are given, as they usually are. The supercargo is simply an agent, and is limited like other agents to the authority vested in him by his principal. Yet, as in the case of some other agents, ship masters for example, by construction of the law new authority is conferred upon the supercargo by the existence and force of necessity; and it has been expressly held that if by any sudden emergency it becomes impossible for the supercargo to comply with the precise tenor of his instructions, or if a literal execution of them would defeat the objects of the shipper and amount to a sacrifice of his interests, it then becomes the duty of the supercargo to do the best he can for the shipper; and his acts done *bona fide* and with a reasonable discretion, in such an exigency, are binding upon the latter. A supercargo, like a master or foreign factor, generally buys and sells in his own name. To cases of this sort, that is to say, when the act may be lawfully done in the sole name of the agent, the law seems to apply the same doctrine, in the event of the death of the principal, as to cases of an authority coupled with an interest; namely, that the authority is not extinguished by the principal's death, but may still be validly executed in the name of the agent; so that the acts of the supercargo in a foreign port, even after the death of the owner of the cargo, and while that event was unknown to him, are binding upon all parties.

SUPERIOR, LAKE (Fr. *Supérieur*, upper), the uppermost of the N. W. lakes of North America, and the largest body of fresh water on the globe. It is included between lat. 46° 30' and 49° N., and long. 84° 50' and 92° 10' W.; greatest length from E. to W. 360 m.; greatest breadth, across its central portion, 140 m.; area, 82,000 sq. m. Its length of coast is about 1,500 m., its mean depth about 1,000 feet, and the level of its surface above the sea 627 feet. The boundary line between Canada and the United States passes from Lake Huron up the river St. Mary's, the outlet of Lake Superior, through the centre of the lower half of this lake, to the mouth of Pigeon river on the N. shore, between Isle Royale and the Canadian coast. This island was allowed to fall on the American side of the boundary in compensation for one of the islands at the mouth of the St. Mary's river. The S. coast of the lake from the outlet to Montreal river belongs to the upper peninsula of Michigan. From this river to the river St. Louis at Fond du Lac the

coast belongs to Wisconsin, and thence round to Pigeon river to Minnesota. Toward each extremity the lake contracts in width, and at the lower end terminates in a bay which falls into the outlet, the St. Mary's river, at the two opposite headlands of Gros Cap on the N. and Point Iroquois on the S. Thence to the mouth of the St. Mary's at Lake Huron is about 60 m. The navigation of this river is interrupted 20 m. below its source at the falls of St. Mary, or, as the place is commonly called, Sault Ste. Marie. Here the river descends in a succession of rapids extending $\frac{1}{4}$ of a mile from 18 to 21 feet, the fall varying with the stage of the water in Lake Superior. Birch canoes run these rapids safely, though they appear full of rocks; they have also been run by one sailing vessel, and a sail boat has ascended them before a strong wind. A ship canal has been constructed past the falls by the U. S. government, so that now the lake is accessible to vessels from the Atlantic ocean. It is only through the outlet that Lake Superior has been reached by any ordinary mode of travel, and while the territory belonged to the Indians the fur companies had exclusive control of this means of access. It is only very recently that communication has been opened by roads from Fond du Lac to the Mississippi, and from the forks of the Ontonagon, on the S. side of the lake, into the settled portions of Wisconsin. The latter road, pursues a S. course to Lac Vieux Desert, and then branches, one route turning E. toward Green bay, and the other following the course of the streams that lead into the Wisconsin river. The settlements are separated by about 100 miles of poor lands with no productions of interest excepting pine timber. The region abounds with small lakes, and large districts are said to be covered with boulders of great size, and so numerous that there is no soil and no vegetable growth. Until the opening of these roads, during the long winter from December to May, the region was entirely shut out except to the mail carriers and occasional travellers, who were able to make on snow shoes the journey of a week through the wilderness that separates the lake from the settlements on Green bay.—Thus remote and isolated, the great lake continued almost unknown nearly to the middle of the present century. Even the settlements of the Indians upon its shores were unimportant, except at Sault Ste. Marie, where they procured abundance of white fish, trout, &c., and at La Pointe, a pleasant island near the upper extremity. They often traversed its waters, however, in their hunting, fishing, and warlike excursions, keeping near the shores in their frail bark canoes. The early Jesuit missionaries visited them in these haunts, and the French *voyageurs* and fur traders were early acquainted with the lake, as they made it a part of their great route to the more distant trading posts of the north-west. (See FUR.) The earliest mention made of the lake is in the

aries, Charles Raymbault and Isaac Jogues, who, on Sept. 7, 1641, left their mission at the head of the bay of Pentanguishene (in Georgian bay) and passed up in a birch canoe to Sault Ste. Marie. There they found a village of 2,000 Chippewa Indians, and from them heard of the lake beyond, which they called Kitchi-gummi (big lake), greater than either of the lower lakes, and reaching toward the west to the country of their dreaded enemies the Sioux, and to the great prairies, where roamed herds of buffalo and deer. René Mesnard passed up into the lake in 1660, and spent the winter on Point Keweenaw on the S. coast; and in August the next year he was lost in the woods between the head of Portage lake and Lake Superior. Allouez, another missionary, traversed the lake in 1666, and remained two years, visiting its shores as far as Fond du Lac, where he learned from the Sioux of the great river Messepé (Mississippi). In 1668 a permanent mission was established at Sault Ste. Marie by Claude Dablon and Jacques Marquette; and in May, 1671, at a grand council assembled at this place, at which were present officers of the king of France, formal possession was taken of the country for the French crown. In a volume of the *Relations de ce qui s'est passé de plus remarquable aux missions des pères de la compagnie de Jésus en la Nouvelle France*, published in 1672, there is a very creditable map of the lake for the opportunities there had been of preparing it. The occurrence of native copper in this region was noticed as early as 1659-'60; and it is particularly dwelt upon in the *Relation* of 1669-'70. Charlevoix, in his *Histoire de la Nouvelle France* (Paris, 1744), also makes mention of copper, and of its being collected and made into chandeliers, crosses, and censers at Sault Ste. Marie. The first Englishman who spent some time at Lake Superior was a trader named Alexander Henry, who was attracted by the indications of copper mines in the region, and in 1771 employed men to commence mining near the forks of the Ontonagon river, and in 1772 removed them to the N. shore of the lake; the enterprise, however, proved unsuccessful. An account of his experience of 16 years in this part of the country was published in a volume of travels and adventures in 1809. Gen. Cass conducted an exploration through the lake country in 1820 for the U. S. government; and Mr. H. R. Schoolcraft, who accompanied the expedition as mineralogist and geologist, published his observations in a work entitled "Narrative Journal of Travels" (Albany, 1821). Major Long, in returning from his western expedition of 1819-'20, passed along the N. shore of Lake Superior, and the region is noticed in the report by W. H. Keating (Philadelphia, 1824). The United States acquired possession of the territory lying S. of the E. portion of the lake by treaties with the Indians in 1836-'7, and of the remainder as far up as Montreal river in 1842-'8; and immediately afterward surveys and geological explorations

were undertaken by the general government and the state of Michigan, followed by a multitude of private and company enterprises set on foot from the eastern and western states with the view of securing the best of the copper mines. For an account of the resources of this region in the useful metals, see COPPER MINES, vol. v. p. 685; IRON, vol. ix. p. 594; and IRON MANUFACTURE, p. 609. Other matters of interest relating to the lake are alluded to in FUR, vol. viii. p. 20.—Lake Superior is supplied by the drainage of an extensive territory through a multitude of rivers, none however of large size. High lands in general lie near the coast, the long slopes from which are directed away from the lake and the short slopes toward it. The rapid fall prevents the navigation even by canoes of most of these streams, but provides excellent water power, which is almost everywhere available. At the head of the lake the St. Louis enters from the N., where its waters, navigable only by light canoes, interlock with those of the Mississippi and with those that flow into the Lake of the Woods. Montreal river, which divides Wisconsin from the upper peninsula of Michigan, is navigable by canoes only in the places between its numerous falls. The Ontonagon, the most important of the rivers, is entered by the vessels that navigate the lake, and is ascended by flat boats up to the range of the trap hills that contain the copper mines, 20 m. above its mouth. This river with its branches drains an area of about 1,800 sq. m. Its E. branch heads near a branch of the next largest river, the Sturgeon, which flows into Portage lake at the base of Keweenaw point. This small lake, which almost cuts through the point, is by improvements at its outlet rendered navigable for the lake boats, and they pass up close to the important mines worked upon its banks. The rivers on the N. side flow through a rough granitic country, and are interrupted by numerous falls, many of which are highly picturesque. The coast of the lake is for the most part rocky, and on the N. side is much indented by deep bays surrounded with high rocky cliffs, back of which the country soon rises in bleak and dreary mountains. Numerous islands are scattered about this portion of the coast, and many of them rise precipitously to great heights directly up from the deep water. Some present castellated walls of basalt, and some rise in granitic peaks to various elevations up to 1,800 feet above the level of the lake. Nowhere upon our inland waters is the scenery so bold and grand as on the N. shore of Lake Superior. The irregularities of the coast with the general depth of water here afford numerous good harbors, which however in this unfrequented region are as yet of little service, while on the opposite coast such places of refuge are much wanted.—The largest island in the lake is Isle Royale, 20 m. from the N. shore and 45 m. from Keweenaw point. It extends N. E. and S. W. 45 m., with a breadth of 8 m., and is

made up of parallel ridges of amygdaloidal trap, greenstone, and sandstone, following the same course with the island, and at the N. E. extremity running out in long fingers into the lake. The harbors on the sides are elongated inlets, due to the same geological structure; and the same may be said of those on the opposite shore of Keweenaw point. The determination of the coast lines by the wearing action of the waters upon rocks of different degrees of hardness is remarkably exemplified everywhere along the shores of Lake Superior. The great waves, often heavily charged with ice and driven by the terrific storms of this northern region, batter with tremendous force the hardest rocks, and in the long succession of ages scoop out the softer strata, following them up the narrow lines of their bedding, or excavating them from their more irregular repositories, leaving the high cliffs worn into strange forms suggestive of rude architectural resemblances, and honey-combed with caves, into which when the lake is still boats may enter. Such is the character of the precipitous walls of red sandstone on the S. coast, famous in all the earlier accounts of the lake as the "Pictured Rocks." They stand opposite the greatest width of the lake and exposed to the greatest force of the heavy storms from the north. The effect of the waves upon them is not only seen in their irregular shapes, but the sand derived from their disintegration is swept down the coast below and raised by the winds into long lines of sandy cliffs. At the place called the Grand Sable these are from 100 to 800 feet high, and the region around consists of hills of drifting sand. Similar exposures of red sandstone with sandy beaches and cliffs in their vicinity form portions of the coast above Keweenaw point. The point itself is formed of ridges of amygdaloidal trap, greenstone, and sandstone, like those of Isle Royale, which toward the S. W. gradually recede from the coast. At the Porcupine mountains, 20 m. above the Ontonagon river, the same formations again appear in bold hills rising near the lake to more than 1,000 feet in height, and other groups of the same rocks continue to be met with in proceeding to Fond du Lac. The straight line of coast thence to Pigeon river, running with the course of the stratification, is composed of metamorphic slates and sandstones with interstratified traps and porphyries. Dikes of greenstone frequently cut across the strata; and comparatively recent deposits of red clay, marl, and drift occasionally interrupt the superficial continuity of the older formations. The argillaceous slates, hornblende, and granitic rocks that form the hills back from the shore come out to the lake, and make up the mountainous coast about Thunder bay and Neepigon bay on the extreme N. of the lake. Veins of copper ores are frequent among the rocky islands of this vicinity, and on one known as Prince's island the ores were found to be highly argentiferous. No mines, however, are now worked on the N. shore. Further east,

the rocks on this side are more of granitic character. Headlands of granite and basalt are met with on the S. coast also between the Pictured Rocks and Keweenaw bay. Michipicooten island, belonging to Canada, is of greenstone, and contains native copper and silver; but the attempts to work the mines have not been successful. The island is 18 m. long, and the hills upon it rise to the height of 800 feet. Of the islands on the S. side, one of the most important is Grand island, just above the Pictured Rocks, a fertile tract of land covered with sugar maples, birch, and other hard woods, and now partly under cultivation; it makes a fine harbor on its S. side. Between it and Keweenaw point, and hardly within sight of land, is a remarkable rock of metamorphosed sandstone, standing about 4 feet above the water, and occupying a space of about 50 by 20 feet. Dangerous shoals extend from it N. N. E. and N. N. W. in parallel ridges with deep intervening hollows. Near the upper extremity of the lake is the group of islands called the Apostles, upon the largest of which, Madeleine island, is the old Indian settlement and trading post of La Pointe. Near it on the mainland is the new settlement of Bayfield, and above at Fond du Lac the new town of Superior. The other settlements of importance are those on the range of the copper and iron mines, and at their outlets at the mouth of the Ontonagon, Eagle River, Eagle Harbor, and Copper Harbor on Keweenaw point, and the town of Marquette above Grand island. A considerable population is supported on the shores of Portage lake, where several very rich copper mines are worked in the trap range which crosses this lake. At the head of Keweenaw bay is an old Indian settlement and mission called L'Anse; and on Thunder bay was formerly another at the Canadian trading post called Fort William, on the route by the Kaministiquia river to the more remote posts to the N. W.—The country immediately bordering Lake Superior is for the most part either too sandy or too rocky for fertility; but a few miles back on the S. coast, especially on the trap ranges, the soil is deep and rich, and supports fine forests of hard maple, birch, red oak, ash, hemlock, and in the lower grounds white cedar, spruce, tamarac, &c. White pine is scattered through the woods everywhere, and is very abundant about the heads of most of the rivers. On the N. shore the forest growth is of the inferior sorts of wood, and the trees are mostly stunted. On the islands the birches, poplars, spruce, fir, and cedars run up in long slender poles, and the rocks are often covered deep with moss, making the travelling over them dangerous from the hidden cavities. Multitudes of bushes spring up where the wooded hillsides have been burned over, and the most abundant everywhere among them is the wild raspberry. Its fine fruit may sometimes be gathered on the N. shore, together with wild currants, gooseberries, strawberries, whortle-

berries, blueberries, mountain cranberries, wild cherries, and other fruits, all ripening together in the short summer of this high northern latitude. The crops that thrive best upon the farms about the mines are potatoes, turnips, hay, and oats. The natural meadows about the small lakes and others produced by old beaver dams make excellent pasturage as well as mowing, and cattle find good grazing also during the summer by ranging through the woods. Corn does not mature, but most garden vegetables, as cabbages, beans, peas, beets, carrots, cucumbers, &c., thrive luxuriantly. Though the summers are short, the days are long, and vegetation under the continued sunlight comes forward with surprising rapidity. The deep covering of snow, which lasts almost from the first fall to the opening of spring, keeps the ground warm and mellow, in excellent order for the next crop. It rarely freezes under this protection, and potatoes often renew themselves without replanting; they have been found growing as if wild in a swamp near the mouth of the Ontonagon, in land that could not have been planted for 10 years or more. There are few good roads through the country, the travelling in the summer being chiefly by water; in the winter the underbrush is mostly covered by the snow, and as this falls nearly every day and freezes every night, a hard crust is found almost everywhere upon which those who are accustomed to snow shoes pass easily through the woods in any direction. The country contains little game; deer are scarce, and the animals hunted for their furs, as the beaver, otter, marten, and silver fox, have been almost exterminated. Wolves are rarely encountered, and the largest animal often met with is the porcupine. Partridges are abundant, wild pigeons also in some seasons, and ducks upon the rivers. The lake contains many varieties of excellent fish, some of which, as the white fish, are better than some kinds found in the lower lakes. Lake trout are caught of large sizes, but they are inferior to the rarer siskiwit and muscalonge. Suckers are abundant, and brook trout are common in nearly all the rivers and brooks.—The mineral productions of the lake have been stated in the articles COPPER MINES and IRON MANUFACTURE, already referred to, up to the time when the volumes containing those titles were printed. The statistics down to the end of the year 1861 are presented in the following tables from the circulars of Messrs. Dupee, Beck, and Sayles of Boston:

Years.	Tons.	Average price per ton.	Value.
Total production of ingot copper to close of 1867.....	18,954	\$500	\$9,477,000
Shipments of 1858.....	8,500	480	1,610,400
" 1859.....	4,200	480	1,992,000
" 1860.....	6,000	420	2,520,000
" 1861.....	7,400	420	3,108,000
Total	40,054		\$13,647,000

The production of the several mines for the last 8 years in rough copper as shipped was as follows, the weights of the barrels being deducted, and the results given in tons of 2,000 lbs. and tenths:

The annual shipments of rough copper, according to the official statements made to the Michigan legislature, have been as follows:

1854, lbs.	1858, tons.	1859, tons.	1860, tons.	1861, tons.
1854, lbs.	1,800	1858, tons.	1,458	
1855, ".....	29	1859, ".....	2,800	
1856, ".....	229	1860, ".....	3,196	
1857, ".....	516	1861, ".....	5,726	
1858, ".....	708	1862, ".....	5,759	
1859, ".....	640	1863, ".....	5,896	
1860, ".....	872	1864, ".....	7,245	
1861, ".....	887	1865, ".....	9,200	

The shipments of iron ores from the lake have been as follows, commencing in 1855:

1855, tons.	1859, tons.	1860, tons.	1861, tons.
1855, tons.	1,457	1859, tons.	80,000
1856, ".....	11,507	1860, ".....	150,238
1857, ".....	26,184	1861, ".....	50,000
1858, ".....	30,337		

In 1861 only about 3,000 tons were shipped after the middle of September, all the vessels having been withdrawn to go into the grain trade. The production of pig iron in 1858 was

2,000 tons; in 1859, 6,000; and in 1860, 6,500. In 1861 there were 5,389 tons shipped, and the product, it is thought, was larger than in 1860. The average value of the ore delivered on the docks ready for shipment is about \$3 per ton gross, and of pig iron about \$22.50 per ton.

SUQUAMISH, a new W. co. of Washington territory, bordering on the Pacific, and intersected by the Sawamish river; area, 500 sq. m.; pop. in 1860, 162.

SURAT, a walled town of British India, in the presidency of Bombay, capital of the province of Guzerat, situated upon the left bank of the river Tuptee, 20 m. from its mouth in the gulf of Cambay, and 160 m. N. from Bombay; pop. 180,000. There is an English church, several handsome mosques and temples, numerous Hindoo and other schools, and an extraordinary institution, called the Banian hospital, founded and richly endowed by the Jains, for the treatment and cure of diseased animals of all descriptions.—Surat is a place of great antiquity, and is mentioned in the ancient Sanscrit poem, the *Ramayana*. When the Mohammedans ruled Hindostan it was their chief port of embarkation on their pilgrimage to Mecca. The Portuguese began to trade with Surat about 1561; and in 1606 the English obtained commercial privileges from the emperor Jehanghir. In 1612 they established a factory, and 8 years afterward it became their chief station on the W. coast of India, and remained so till 1686, when it was removed to Bombay. In 1796 the population was estimated at 600,000, and it had then greatly declined in consequence of the loss of its trade. In 1800 the British took the entire government from the nabob, allowing him to retain his rank, and agreed to pay him and his heirs 100,000 rupees (\$50,000) annually, and 20 per cent. of the surplus revenue, after deducting the expenses of collection.

SURETY, in law, a person who binds himself to fulfil, either wholly or in part, the engagement of the principal obligor. For those cases in which the surety expressly assumes the obligation technically known as a guaranty, or in other words engages for the performance of another, see the article GUARANTY. When two parties join in making a promissory note, as matter of strict law, both promisors are equally liable; but if it be shown that, as matter of fact, the note was given at the request and for the sole benefit of one of the makers, he is, equitably at least, primarily responsible for payment of the whole; or in other words, he is the principal in the obligation, while his co-signer is the surety. So if a sale be made to two on the faith of their joint promise of payment, the legal obligation of the buyers is the same whether the promise was given for the common advantage, or was designed only to enable one to make the purchase by assisting him with the credit of the other. But if the purchase were in fact made under the latter condition, the effect is in equity to raise the relation of principal and surety, and

* From tributaries. The mine now belongs to the Pittsburg and Boston company.

to throw upon the former the whole burden of the performance. If, then, in case either of the note or the sale, the surety in fact be compelled (as, according to the tenor of his obligation, he obviously may be) to pay the whole, equity declares that he is entitled to complete reimbursement from the principal in fact, or in other words, from him who gets all the benefit and is therefore really the responsible party. Equity also declares that, in order to secure this reimbursement, the surety is entitled to the benefit of all the security which either the rules of law or the express acts of the parties have given to the obligee or creditor; and if, by any negligence or other acts, the obligee defeat these rights of the surety, he forfeits his right of action against him. It may be proved in a common law court, by any competent evidence, that in a contract executed by two, one was principal and the other was surety, even though the contract neither disclose nor suggest any such thing. If the creditor or obligee is fairly informed of the relation of principal and surety existing between the parties, he is bound to take care that no act of his shall destroy or lessen the surety's right of indemnity from the principal debtor. If therefore he declare that he will look solely to the principal for payment, so that the surety is induced to omit taking security from the latter; or if he tell the surety that the debt has been paid so that he relinquish to the principal his security; the surety will be in both cases discharged from his obligation to the obligee. But though the debt be already due, the mere inaction of the creditor to pursue his remedies against the principal will not discharge the surety, nor will positive indulgence to the principal have this effect; but if the delay be granted in pursuance of any binding agreement with the principal, so that the surety cannot pay the debt and then proceed for indemnity against the principal, the creditor's act releases the surety. The mere suspension of proceedings once commenced against the principal does not discharge the surety; for as no positive advantage has been gained against the principal, the surety has no more ground for complaint than he has in the case of mere inaction. But as the surety is entitled to the benefit of all securities given by the principal, he is discharged if the creditor's inaction or negligence have rendered these securities valueless. So, when a creditor had surrendered to the principal debtor a horse and gig belonging to the latter, which he had held as security for the debt, it was decided that his act barred any proceeding against the surety. In short, though the creditor is not bound, so far as the surety is concerned, to pursue the ordinary legal remedies against the principal, yet he is bound, in respect to all remedies given him by way of pledge or security or by other act of the parties, to hold or pursue them diligently in behalf of the surety; and if he relinquish any such remedy without the knowledge or against the will of the surety, he shall lose

his claim against the latter to the extent of the right surrendered. It has been held in a leading case in New York, that if an obligee or holder of a note, who is requested by a surety to proceed without delay to collect the money of the principal, who is then solvent, omits to proceed against the principal, and the latter afterward becomes insolvent, the surety will be exonerated at law. But in many of the states this doctrine has been rejected, and even in New York it has been partially disapproved. The general ground of objection to it is that, though a surety may, through a court of equity, compel a creditor to prosecute his demand against the principal, mere notice or request *in pais* to do so gives the surety no claim to be discharged. On the ground that there was no court of chancery in Pennsylvania, it was held there that the surety's request must suffice to release him, as otherwise there were no means of enforcing his rights. In some of the states, however, the rule adopted in the leading case in New York has been embodied, with some restrictions, in express statutes.

SURF BIRD (*aphriza virgata*, Gray), a wading bird of the plover family, and sub-family *cinclina* or turnstones. The bill is about as long as the head, with vaulted obtuse tip and compressed sides; wings long and pointed, with the first quill the longest; tail moderate and even; tarsi long as middle toe, robust, with small irregular scales; toes long, free at the base, sides of anterior ones margined, and hind one elevated, slender, and partly resting on the ground. It is about 10 inches long, with the wing 7; dark brown above, lighter on the wing coverts, with white spots and stripes on the head and neck; upper tail coverts and basal half of tail white, the latter terminated with brownish black; under parts white, tinged with ashy in front, each feather having a brownish black crescent. It is found on the Pacific coast of North and South America, and in the Sandwich islands, migrating from northern to temperate regions in winter and back again in summer. It is usually seen on the edge of steep rocks, among the retreating waves, searching for small mollusks and marine animals, allowing the surf sometimes to dash over it, whence the common name; its flight is short, with a quick and jerking motion.

SURGEON. See **PHYSICIAN AND SURGEON.**
SURGEON, a bird of the stork family. See **JACANA.**

SURGERY, or **CHIRURGERY** (Gr. *χειρ*, the hand, and *εργον*, labor), that department of the art of healing which appertains to the diagnosis, prognosis, and treatment of the class of diseases which require manual or instrumental measures for their cure. The sphere of surgery is more limited and at the same time more accurately defined than that of medicine. Surgery divides tissues or parts improperly united, and unites those which have been divided when they should remain in union; separates whatever has become dangerous or inconvenient to

the patient; removes foreign bodies, or parts of the body which from disease or loss of vitality have become foreign, whenever they exert a hurtful influence on the animal economy; restores to their cavity or replaces in their normal position portions of the body which have become displaced; checks the loss of blood from wounded or divided blood vessels; reduces inflammations, or removes the purulent or phlegmonous matter which may have been deposited by them; repairs and corrects deformities and distortions; and effects the replacement of lost tissues. Its means of accomplishing these results are the hand, lint, bandages, and apparatus of various kinds, cutting, crushing, and probing instruments, catheters, bougies, sounds, forceps, specula, &c., and the various forms of cauteries, direct and indirect, liquid and solid.—The earliest surgeons of whom there is any record were the Egyptian priests. Of their skill in embalming the bodies of the dead there is ample evidence, and Kenrick says that "on the walls of the ruined temples of Thebes, basso-relievos have been found displaying surgical operations and instruments not far different from some in use in modern times." According to Herodotus, we owe to them the use of the moxa and the adaptation of artificial limbs. Among the Jews in their early history there is but little evidence of surgical skill, and that little is confined to the priests. Circumcision was indeed skilfully performed, but this required little surgical ability; and in the treatment of wounds and fractures, even at a late period (2 Kings i. 2), the more skilful Phœnician priests seem to have been preferred. In Greece, surgery is as ancient as the mythic period of its history. Chiron the centaur, born in Thessaly, and skilful in the application of soothing herbs to wounds and bruises, is the legendary father of Greek surgery. But Æsculapius, the son of Apollo, said by some to have been the pupil of Chiron, though others call him his predecessor and superior, won the highest fame in that early time for surgical skill. He is said to have been deified on account of his wonderful success about 50 years before the Trojan war. Temples were reared for his worship, which became the repositories of surgical knowledge, at Epidaurus, Onidus, Cos, and Pergamus. Homer has immortalized his two sons, Podalirius and Machaon, the companions of Agamemnon in the Trojan war (about 1192 B. C.), where they rendered essential service in healing the wounds of the Grecian heroes. Venesection was practised by Podalirius, while Machaon possessed the greater skill in the treatment of wounds. Their knowledge, however, seems to have been limited to simple operations like the removal of darts, the checking of hæmorrhage, and the assuaging of pain by soothing applications. Of the treatment of fractures they appear to have been entirely ignorant, for in these Homer invokes Apollo only, never calling on the surgeons for aid. For 600 years after the Trojan

war we find little said of the surgeon's art. The Asclepiades, or descendants of Æsculapius, retained the monopoly of this as well as medicine in their family. They had established in this period 8 schools of medicine, at Rhodes, Onidus, and Cos. Pythagoras, about 600 B. C., established at Crotona a new school of medicine, in which his peculiar philosophy was probably applied to the art of healing; among its early pupils was Damocedes, eminent as a surgeon, who when taken captive by the Persians reduced the dislocated ankle of Darius, and removed or in some way cured the cancerous breast of his queen Atossa, after the Egyptian physicians had failed. The want of anatomical knowledge, no dissections being allowed, was a fatal bar to any considerable progress in surgery. Hippocrates more than any of his predecessors advanced surgical treatment; he reduced dislocations and adjusted fractures, clumsily it is true, and with great pain to the patient, but with some success; he used the trephine, many times unnecessarily; he applied the forceps in accouchement, made incisions into the kidney for the removal of calculi, performed amputations, perforated the cavity of the ribs in empyema and hydrothorax, and used cauteries of all sorts, moxas, red-hot irons, wood saturated with oil, &c. He also made use of lints and issues, and operated for *fistula in ano*. Interdicted from human dissection, he practised the dissection of the ape tribe as nearest to man in anatomical structure, and thus obtained much knowledge. For more than 100 years after the death of Hippocrates we meet few names of note in surgery. Diocleso Carystus, one of the Asclepiades, obtained some notoriety for his skill in wounds of the head; and Praxagoras of Cos, the last eminent name among the descendants of Æsculapius, treated quinsy and other diseases of the throat by incision and excision, and made incisions into the bowels where other means failed to remove obstructions. The founding of the Alexandrian school under Ptolemy Soter in 300 B. C. was another important epoch in the advance of surgery. Herophilus and Erasistratus, the two great leaders of the medical school of that university, if it may be so called, were eminent both as physicians and surgeons; with them commenced the practice of human dissections. The extirpation of the spleen, and the application of remedies direct to scirrhotic and tumors of that viscus and of the liver, were among the bold operations of Erasistratus. To him also belongs the invention and application of the catheter in cases of retention of urine. The pupils of these eminent surgeons invented bandages of peculiar forms, and introduced the tourniquet and contrivances for reducing dislocations of the femur. One of them, Ammonius, employed an instrument for lithontriptic purposes, anticipating Civiale's process.—Rome in the first 600 years of its history produced no surgeon of note. One Archagathus, who, with a courage worthy of a profounder knowledge,

attempted with ill success some operations in the consulates of Lucius Æmilius and Marcus Livius, was driven from the city by an enraged populace. Asclepiades of Bithynia (96 B. C.), though attaining some reputation as a physician, soon abandoned surgery from fear of the populace. We owe to him however the recommendation of acupuncture in ascites, general and local bleeding, and laryngotomy in some affections of the throat. Celsus was the greatest of the surgeons of ancient Rome, and his observations on injuries of the head, on cataract, on the ligature of wounded arteries, hernia, lithotomy, fractures and dislocations, amputations, and carbuncle, are all fully accordant with our present knowledge on these subjects, at least in the principles laid down. Aretæus, the first to use the cantharides blister, Heliodorus, Antyllus, and Rufus the Ephesian, all of whom flourished between A. D. 50 and 120, added to the surgical knowledge of the time new views of the treatment of injuries of the head, the resort to arteriotomy instead of venesection in sudden emergencies of inflammatory action, bronchotomy in some acute diseases of the throat, the radical cure of hydrocele by free incision of the parts, and a more thorough investigation of diseases of the kidneys and bladder. Galen devoted more attention to medicine than surgery, but his observations on hernia, on luxation of the femur backward, and on the application of the trephine to the sternum in empyema, are of importance. In the early period of Christianity surgery languished; the early Christians opposed dissection as strongly as the pagans, and by attributing the power of healing wounds to martyrs and their relics discouraged all efforts at improvement in surgical science. The first eminent name among the surgeons of the dark ages is Aëtius (500 to 550), whose surgical writings are numerous and valuable. He practised scarification of the extremities in anasarca; operated for aneurism; endeavored to dissolve urinary calculi by internal remedies; removed hæmorrhoidal tumors with the knife; discussed with great ability the subject of hernia and all the operations for it; and wrote largely on encysted tumors, diseases of the testes, injuries to nerves and tendons, and diseases of the eye. Mingled with his numerous valuable observations, we find, however, evidence of his faith in amulets, charms, &c., to avert or cure disease. Alexander of Tralles, a younger contemporary of Aëtius, wrote treatises, now lost, on diseases of the eye and on fractures, which were highly commended for their originality by some of his successors. Paulus Ægineta, in the 7th century, was a surgeon of eminence and considerable originality. His 6th book has been considered by many as the best body of surgical knowledge prior to the revival of letters. He recommended topical in preference to general bleeding, as more effective in reducing local inflammation; resorted to copious venesection to accelerate the painful descent of

calculi through the ureters; opened internal abscesses with caustics; defined the points for performing paracentesis in ascites; made his incision in lithotomy on one side of the raphe instead of the centre as Celsus had recommended; urged the necessity of small incisions into the bladder; described with accuracy and treated with success many of the numerous varieties of aneurism; performed extirpation of the mammae by crucial incision; practised both laryngotomy and tracheotomy, the latter as a means of carrying on respiration during occlusion of the larynx; treated of fractures of the patella; and was the originator of the obstetric operation of embryotomy.—The Arabian physicians, who rose into distinction as those of the West declined in reputation, did little for surgery. Rhazes (852–932) described for the first time *spina veniosa* and *spina bifida*, cauterized the wounds from the bites of rabid animals, opposed the use of the knife in cancer except when limited and when the whole tumor could be removed, and gave a clear and satisfactory description of the treatment of hernia. Avicenna (980–1036) introduced the flexible catheter and the operation of depression for cataract. Albucasis (died 1122) was extremely partial to the actual cautery, introduced an instrument for the cure of *flatus lachrymalis*, invented the probang, and in wounds of the intestine practised union of the divided parts by suture with success. Avenzoar, about the beginning of the 12th century resident at Seville in Spain, wrote on surgery, but added little that was new to the science.—In Catholic Europe medical practice and what of surgery remained was mostly in the hands of the clergy until, by the edict of the council of Tours in 1163, they were interdicted from all surgical practice. The Jews were at this period and for a century or two later in high repute as physicians, but they seem to have had a dislike to surgery. Guy de Chauliac, a priest, compiled from the Greek and Arabian authors the earliest work of modern times on surgery, but with very little judgment of what was worth retaining. For two centuries and more surgery was mainly in the hands of the illiterate barber surgeons. The revival of surgical science dates from the appearance of Vesalius as a teacher of anatomy in Italy, followed soon after by Fallopius and Eustachius. Surgery was then for the first time put upon a sound and scientific basis, that of careful dissection, and Ambroise Paré, a French army surgeon who had educated himself in anatomical science, was the first of its great lights. He was surgeon successively to four kings of France, and was attached to the French armies as surgeon-general down to 1569. To him we owe the revival and improvement of the practice of tying the arteries after operations or wounds, instead of cauterizing them with hot iron or boiling oil. His treatise on gun-shot wounds, though the first ever written on that subject, is a work of great value. The pupils of Paré added little lustre to

their master's name; but in Italy at the close of the 16th century Fabricius ab Aquapendente flourished at Padua, and his *Opera Chirurgica*, the first really valuable treatise on surgery of modern times, passed through 17 editions. He was the preceptor of Harvey. Wiseman, sergeant surgeon to Charles II., was the first eminent surgical writer and practitioner in England. His recommendation of immediate amputation in military practice, when the preservation of the limb was impossible, has been followed from that time to the present. He left 8 treatises on surgery, which are not without value even at the present day. The flap operation in amputation is claimed for James Young, an English surgeon contemporary with Wiseman, and also for two French surgeons, Verduin and Sabaurin, of the same period. In Germany during this century, Hildanus, Scultetus, Purmann, and Heister were the principal surgical writers and practitioners. The last named, a professor in the university of Helmstedt, was the author of a system of surgery which has been translated into most of the languages of Europe, and is still regarded as an authority. The tendency of German surgery at this period was to daring and dangerous operations. In Italy the principal names of note were Talia-cotius, the originator of restorative surgery in Europe; Cæsar Magatus, who greatly simplified the treatment of wounds; and M. A. Severinus, who banished the salves and plasters which in Italy had usurped the place of operations. The 18th century witnessed a still greater advance in the science, resulting alike from the profound anatomical and physiological attainments and the brilliant genius of the surgeons of the period. In England, Percival Pott, the best operator of his time, the reformer of the abuses of the actual cautery and the potential escharotics, the discoverer of the form of caries of the vertebra known by his name, and the most judicious writer of modern times on fractures, amputations, injuries of the head, and diseases of the spine; John and William Hunter, the former the greatest master of the principles of surgery in the profession; Cheselden and Douglas, both famous as lithotomists, and the former remarkably successful; Sharp, the able author of the "Critical Inquiry into the State of Surgery;" and the Drs. Monro, father and son, are among the great names of the surgical profession. In France flourished Lapeyronie, at whose instance Louis XV. in 1731 founded the academy of surgery; Jean Louis Petit, the greatest French surgeon of the 18th century; Ledran, Garangeot, and the illustrious Desault, the originator of clinical surgical instruction and the inventor of numerous admirable apparatuses for the treatment of fracture; with a host of others hardly less famous. Among the celebrated surgeons of other European countries were Molinelli, Morgagni, Scarpa, Bertrandi, and Moscati in Italy; Albinus, Deventer, and Camper in Holland; and Platner, Röderer, Cal-

lisen, Rambilla, Theden, and Richter in Germany. During the 18th century the ligature of aneurismal arteries of large size, the treatment of hernia and *fistula in ano*, the cure of *fistula lachrymalis*, and the skilful management of dangerous and difficult parturitions, were the most important branches of surgery in which there was a material advance from the preceding century; the proper construction of instruments also received great attention. The 19th century has, however, done more for the improvement of this science than all the centuries which have preceded it. In England, Abernethy, Sir Astley Cooper, Liston, and others of the highest reputation have passed away, and others hardly less eminent remain; in France, Dupuytren, Roux, Lisfranc, and Larrey had no superiors either in the past or present; and in the United States, where surgery up to the period of the revolution hardly had an existence, and the surgeons who became eminent during the war did so rather from the force of genius than from the instruction they had received, the science has won its highest trophies in the relief of human suffering. The objects to which the attention of the skilful surgeons of the present century has been directed have been not so much the invention or origination of new and daring operations, though the profession has not been wholly free from the charge of indulging in "heroic" surgery, as the simplification of its processes, the perfection of the instrumentalities used, the introduction of anæsthetics, and the avoidance of capital operations wherever the desired result can be obtained by a less brilliant mode of treatment. The following may with propriety be particularized as among the improvements of the age in surgery: resection of the bones at the joints; the preservation of the periosteum and consequent development of new bone; partial amputations of the foot; amputations at the thigh and shoulder joint; the ligature of arteries within the trunk and immediately at their departure from it; the resection and removal of portions or even the whole of the upper or lower jaw; the operations for cleft or deficient *velum palati* or palatine vault; the opening by longitudinal section of the air passages at different points to avoid asphyxia; the resection and extirpation of the uterus, of the ovaries, and of the lower portion of the rectum; the adoption of water dressings in the treatment of wounds; the introduction of the silver suture; the adoption of the gum and *papier maché* splints in fractures; the processes for remedying disunited fracture; the substitution of milder means for the trephine in all except the most serious cases; the improved treatment of ulcers and abscesses; the cure of the most formidable aneurisms by the ligature of the carotid, subclavian, axillary, humeral, and external and internal iliacs; the treatment of varicose veins; the successful reduction of hernia; the successful treatment of calculus both by lithotomy and lithotripsy, in consequence of the great improve-

ment in the processes and instruments of the latter operation; the treatment of stricture, of injuries and diseases of the trachea and larynx, and of rectal diseases; the diagnosis and treatment of tumors, whether encysted, fatty, vascular, or malignant; the treatment of hydrocele; the cure of strabismus; the restorative processes, by which the nose, lip, &c., are re-formed from adjacent tissues; and the treatment of harelip and of club-foot. Military surgery has made great advances during this century.

SURINAM. See **GUIANA**.

SURINAM, a river of Dutch Guiana, which rises in the mountains on the S. frontier, flows through the centre of the colony, and falls into the Atlantic 16 m. below Paramaribo after a course of about 800 m. It has several tributaries, and is navigable for large vessels about 80 m. from its mouth. The banks of the Surinam are generally wooded, and between Paramaribo and the sea are well cultivated.

SUROWIECKI, WAWRZYNIEC, a Polish author, born near Gnesen in 1798, died in Warsaw, June 9, 1827. He studied at Warsaw, spent some years in foreign countries, especially at Dresden and Vienna, and after his return to Warsaw held various civil offices in the national service. His principal works are: *O upadku przemysłu i miast w Polsce* ("On the Decline of Industry, and Towns in Poland," Warsaw, 1810), and *Śledzenie początku narodów sławiańskich* ("Researches on the Origin of the Slavic Nations," Warsaw, 1820).

SURPLICE (Lat. *superpellicum*), a white linen garment worn by the clergy in the performance of divine service. It differs from the alb in having wider sleeves, and was introduced in the 12th century for the purpose of making a distinction between the dresses of the superior and inferior orders of the clergy.

SURREY, a S. E. county of England, bounded N. by Middlesex, from which it is separated by the Thames, E. by Kent, S. by Sussex, W. by Hampshire, and N. W. by Berkshire; area, 789 sq. m.; pop. in 1861, 880,685. Beside Southwark and other suburbs of London, the most important towns are Croydon, Guildford, Kingston, Epsom, Reigate, Farnham, and Godalming. That part of Surrey which lies on the Thames and much of the land on the borders of the county is exceedingly rich and fertile. Parts of the shire are famed for the beauty of their scenery. The principal streams are the Wey, Mole, and Wandle, which fall into the Thames. There are extensive market gardens and flower farms, where beside flowers medicinal herbs are raised in large quantities. Numerous canals and railroads intersect the county. Silk, paper, earthenware, leather, ale, &c., are manufactured. Surrey returns 11 members to parliament.

SURREY, EARL OF. See **HOWARD, HENRY**.

SURRY. I. A S. E. co. of Va., bounded N. E. by James river, and S. W. by Blackwater river; area, 840 sq. m.; pop. in 1860, 6,138, of whom 2,515 were slaves. The surface is mod-

erately hilly and the soil fertile. In 1850 the productions were 204,975 bushels of Indian corn, 85,133 of wheat, 65,093 of potatoes, and 14,809 of peas and beans. There were 11 churches. The value of real estate in 1856 was \$860,121, showing an increase of 18 per cent. since 1850. Capital, Surry Court House. II. A N. W. co. of N. C., bordering on Va., bounded S. by the Yadkin, and drained by Ararat and Fisher rivers; area, about 900 sq. m.; pop. in 1860, 10,379, of whom 1,246 were slaves. The surface is in part mountainous and generally hilly. Ararat or Pilot mountain, in the S. E., is the highest peak in this region. The productions in 1850 were 552,454 bushels of Indian corn and 145,472 of oats. There were 3 cotton factories, 7 iron forges, 1 foundry, 11 distilleries, 80 churches, and 2,098 pupils attending public schools. Capital Rockford.

SURVEYING (Fr. *survoir*, to overlook), the measuring of portions of the surface of the earth, either for the purpose of calculating the contents of areas, of laying out tracts of required extent, of establishing roads, or of preparing maps upon which such objects belonging to the surface are represented as the special purposes in view require. The ancient science of geometry grew out of the practice of surveying, and now embodies the mathematical principles upon which the work is conducted. That this science was cultivated by the Egyptians at a very early period is well established, and many of the old Greek writers, as Herodotus, Plato, Diodorus, Strabo, and others, ascribe its origin to changes which annually took place from the inundation of the Nile, and to the consequent necessity of adjusting the claims of each person respecting the limits of the lands. Diodorus says the children of the priests especially, "pay great attention to geometry and arithmetic; for the river changing the appearance of the country very materially, causes many and various discussions among neighboring proprietors about the extent of their property; and it would be difficult for any person to decide upon their claims without geometrical proof, founded on actual observation." The progress of the art of surveying to its higher application in determining the figure of the earth has been traced in the article **EARTH**; and the details of operations in trigonometrical surveys upon a grand scale, are described under **COAST SURVEY**.—The systems of surveying may be classed according to its special objects; as land surveying, for determining the contents of areas, or dividing tracts into lots of smaller dimensions; topographical surveying, which includes, beside the measurement of horizontal lines and angles, that of the variations of level also, so that the superficial inequalities may be graphically represented; hydrographical or maritime surveying, the object of which is the determination of the positions of channels, shoals, rocks, and the shore line; and mining surveying, for fixing the positions of the underground works in mines, so that these can be correctly mapped. Surveys

extending over large territories involve the consideration of the curvature of the earth and the use of spherical trigonometry, and are called geodetic in contradistinction from ordinary surveying over more limited areas, which may with sufficient accuracy be conducted without reference to the figure of the earth, and which may be termed plane surveying. (See *Geodesy*.) These systems all involve the same principles of measuring lines and angles between definite points upon the area included in the survey, and reproducing these upon paper, the lines being reduced to some convenient scale. Calculating the content of the area is commonly the conclusion of the work of land surveying. Various methods may be adopted in conducting these operations. Tracts of any shape or size may be accurately surveyed, if tolerably level and clear, with no other instrument than the surveyor's chain, of which a description has been given under *GUNTER, EDMUND*; and for this may be substituted a measuring tape, a measured rope, or leather driving reins. This is done by measuring all the sides of the tract, and then diagonals from one corner to another, so selected as to divide the tract into triangles as nearly equilateral as possible. The number of diagonals will be two less than the number of sides. In using the chain it is to be kept as nearly horizontal as possible, or if the measurement is made on a slope the variation from the horizontal is to be determined and duly allowed. In case the corners are not visible from each other, intermediate points may be adopted and used for the terminations of lines from corners, the object being in every case to divide the tract into triangles of which the sides are all measured. Proof lines measured from a corner of each triangle to the opposite side serve to rectify the other measures of the triangle, and if perpendicular to the side afford a convenient means of calculating upon the ground the area of the triangle. Perpendiculars to any line are readily laid out with a chain, as carpenters and masons draw right angles by what they call the 6, 8, and 10 rule, the popular application of the principle of the square of the hypotenuse being equal to the sum of the squares of the two other sides. The method is to measure from the point where the perpendicular meets the line, either along this line or along the perpendicular, a distance equal to 6 units of any kind, and then upon the other of these lines a distance of 8 units. The two lines are perpendicular to each other, when the two termini are just 10 units apart. Convenient distances for this measurement might be 8, 4, and 5 rods or chains. Other trigonometrical methods readily suggest themselves. A number of convenient instruments of simple form, known as the surveyor's cross, are in use, for setting out perpendiculars by lines of sight, crossing each other at right angles; and a temporary substitute for them is easily made by sticking a pin in each corner of a square piece of board,

and sighting across these in the direction of the line and at right angles to it. Angles in the field are determined by a chain, by measuring a "tie line" from a measured point on one side to another measured point on the other side. By this means, the boundaries of a tract may be determined when it cannot be conveniently measured off in triangles. A great variety of expedients are adopted for overcoming natural obstacles and determining the extent and shape of inaccessible objects, systems of triangles being in such cases formed outside of and around such objects. Crooked lines are determined by means of perpendicular offsets measured from different points along a straight line run as nearly coincident to the crooked line as may be. In all the methods of surveying, the measurements, together with various incidental observations, are recorded, after some established system, in what are called field notes, and from these the results of the survey are afterward plotted to some convenient scale.—A more common system of surveying is that in which instruments for taking angles are employed in connection with the chain. A graduated horizontal circle with a straight edge, called an alidade, turning upon its central point, which may be conveniently sighted along, furnishes the means of ascertaining the angular distance of two lines when set at their intersection, and the alidade is pointed in the direction of one and then of the other. This involves the principle of the engineer's transit, in which the alidade is a telescope, provided, in the common focus of the object glass and of the eye piece, with cross hairs or delicate filaments, one horizontal and the other vertical. The telescope is supported in a frame, upon a horizontal axis, so that it may be turned completely over, for taking back sights as well as forward sights, and thus rectifying the observation, while the frame turns with the telescope upon a horizontal circular plate, graduated around its margin and furnished with a vernier on each side. If the telescope be fixed to a graduated vertical circle also, and a level is added, the instrument is called a theodolite. With these instruments angles can be determined with great accuracy, especially when the observations are repeated by reversing the instrument and taking the mean, each including the reading of both verniers. With the transit and the chain for measuring distances, tracts of almost any dimensions are accurately surveyed by measuring the angles at its corners, and the correctness of the work is proved when the sum of all the inferior angles is found equal to the product of 2 right angles, or 180° , by the number of sides of the tract less 2; or if the instrument be used by the method called traversing, or "surveying by the back angle" (which consists in noting the angle which each successive line makes, not with the preceding line, but with the first line observed, which is hence called the meridian of the survey), then the reading, on getting round to the last sta-

tion and looking back to the first line, should be 860° , or 0° . A compass and chain may be employed in filling up the interior details of a large survey with the transit; and the compass may be used for determining the magnetic bearing of one of the lines, unless this be astronomically ascertained by observations of the north star or of the shadows before and after noon.—The compass is the instrument in most common use in ordinary surveying. The magnetic needle, wherever the instrument is set, establishes the meridian line, and from this, the sights of the instrument being turned to any other line, the angle of divergence is read on the graduated circle around the compass box. This instrument has been described under its own name, and the method of using it and its defects alluded to; also the more perfect instrument, in which its inaccuracies are obviated, under the head of COMPASS, SOLAR.—The details of surveys are variously modified according to the extent of the area, character of the ground, &c. With the transit or compass, the boundary lines may be all followed out, the angles they make with each other determined, and their lengths measured by the chain; the points of crossing of roads, brooks, fences, &c., measured, and the bearings of these objects taken; and increased accuracy may be given to the work by running diagonal or proof lines, as in chain surveying. Additional checks are furnished by taking at each station the bearings of some marked objects, which, when the work is plotted, should severally fall at the points of intersection of the lines directed toward these objects from the several stations. Sometimes a tract may be surveyed from a measured base line, either a line within or without it, or one of the boundary lines, by placing the compass successively at each end of this line and taking the bearings of each corner; or without a compass the work may be very conveniently performed with approximate correctness by the plane table method, provided no angles are taken less than 80° nor larger than 150° . A drawing board covered with paper is set up at one end of a measured base line, and a ruler furnished with upright sights at each end, exactly over the drawing edge, is set with this edge against a fine needle stuck up in the board, and is then directed successively toward the corners of the tract to be surveyed and any other prominent objects, toward which from the needle lines are to be drawn on the paper. One of these lines should also be in the direction of the measured line. The instrument is then taken to the other end of the measured line, the needle is removed along the last line named on the board a distance corresponding, according to the scale adopted, to that of the measured line on the ground, and the board is so placed as to make the line toward the former station correct. The ruler is then again pointed to the same objects, and lines are drawn toward each from the new position of the needle. Their intersections with the former lines designate the places of these

objects on the plane. The plane table is used in various other ways, as by moving it from one corner to the next, and placing it at each so that the last line drawn coincides with that in the ground. From any central point also radiating lines may be measured to the corners, and the distances measured and marked off according to the proper scale.—Rivers, brooks, and roads are surveyed by measuring a succession of lines following their general course, and taking offsets from the sides of the line. Streets of cities are followed in a similar manner. Distances are sometimes measured upon roads, where expedition is more important than extreme accuracy, by various substitutes for the chain, some of which, as the odometer and pedometer, have been noticed under the former head. One may soon accustom himself to pace in straight lines, and with steps of uniform lengths, the most exact method being to regulate the natural step, rather than to try to attain one of any determinate length, as a yard. The usual average step of a man is that of the English military pace, $2\frac{1}{2}$ feet. The French geographical engineers accustom themselves to take regular steps of $\frac{1}{3}$ of a metre, or 2 feet $7\frac{1}{2}$ inches.—The field work being completed, the figure of the tract surveyed is reproduced upon a diminished scale by what is termed plotting; and from this plot the contents are ascertained by a series of mathematical calculations applied successively to the several divisions; or by the method of calculation of latitudes and departures, for which a table of natural sines is required, unless "traverse tables" giving the latitude and departure for any bearing, as furnished in some books on surveying, are at hand. An approximate estimate of the number of acres included in the survey is sometimes made by drawing the plan upon sheet lead of uniform thickness or upon Bristol board or heavy paper, cutting out the piece on the boundary lines, and weighing it in a delicate balance. The weight may then be compared with that of a similar piece that exactly comprises a definite number of acres, laid out upon the same scale.—The extensive territories of the United States are surveyed upon a peculiar system, planned with reference to the division of the lands into squares of uniform size, so arranged that any tract of 160 acres, or a "quarter section," may have its distinct designation and be readily found upon the map or recognized upon the ground by the marks left by the surveyors. Each great survey is based upon a meridian line run due N. and S. by astronomical measurements the whole extent of the survey in these directions; and upon a "standard parallel" or base line, running E. and W., similarly established with great accuracy. Parallels to these lines are run every 6 miles, usually with the solar compass corrected by frequent celestial observations; and thus, as nearly as the figure of the earth admits, the surface is divided into squares of 6 miles N. and S. and the same E. and W., each one containing 36 square miles or

sections, into which the territory is further divided by meridians and parallels run at every mile; while the half mile being marked on these lines by setting what is called a quarter post, the points are established for the subdivision into quarter sections. The squares of 36 square miles are termed townships, often contracted to "towns;" and each line of them E. and W. is numbered either N. or S. from the base line, and each line of them N. and S. is termed a range and is numbered E. or W. from the meridian. The N. and S. lines bordering the townships are known as range lines, and the E. and W. as township lines. Each survey is designated by the meridian on which it is based; and of these principal meridians there are 5, from the first one commencing at the mouth of the Great Miami river to the 5th from the mouth of the Arkansas river N. The 2d one runs through the centre of the state of Indiana, the 3d from the mouth of the Ohio through Illinois, and the 4th from the mouth of the Illinois river N. The state of Michigan has a distinct meridian, and its base line crosses the lower peninsula of the state from Lake St. Clair to Lake Michigan. The 36 sections of each township are numbered in order, beginning with the N. E. corner and thence proceeding along the N. side of the township to section 6 in the N. W. corner; section 7 commences the next line of sections S., the numbers running E. to 12, and then beginning the 3d line with 13 and running W. to 18, and so on, bringing No. 36 in the S. E. corner of the township. The quarter sections are designated by their position as N. E., N. W., S. E., and S. W. Fractional sections of irregular shapes are admitted on the borders of lakes, rivers, &c. With these explanations any tract may be readily pointed out upon the government maps from its abbreviated description, or any locality in the wildest territory may be correctly defined; thus the S. W. qr. sect. 18, T. 66 N., R. 34 W., meridian Michigan, is traced directly to an old mining location near the N. E. extremity of Isle Royale, Lake Superior. The law which established this system, while it required that the N. and S. lines should be true meridians, also required, what was entirely inconsistent with this, that the townships should be 6 miles square; for the figure of the earth causes the meridians to converge toward the pole, thus making the N. line of each township shorter than its S. line, an inequality which becomes more and more marked the higher the latitude of the surveys. Provision is consequently made for correcting the errors thus caused, by establishing what are called correction lines, which are parallels bounding a line of townships on the N. when lying N. of the principal base, or the S. line of townships when lying S. of the principal base, from which the surveys as they are continued are laid out anew, the range lines again starting at correct distances from the principal meridian. In Michigan these correction lines are repeated at the end of every 10th township;

but in Oregon they have been repeated with every 5th township. The instructions to the surveyors have been that each range of townships should be made as much over 6 miles in width on each base and correction line as it will fall short of the same width where it closes on to the next correction line N.; and it is further provided that in all cases where the exterior lines of the townships shall exceed or shall not extend 6 miles, the excess or deficiency shall be specially noted and added to or deducted from the western or northern sections or half sections in such township, according as the error may be in running the lines from E. to W. or from S. to N. In order to throw the excesses or deficiencies on the N. and on the W. sides of the township, it is necessary to survey the section lines from S. to N. on a true meridian, leaving the result in the N. line of the township to be governed by the convexity of the earth and the convergency of the meridians. Navigable rivers, lakes, and islands are "meandered" or surveyed by the compass and chain along the banks. The instruments employed on these surveys, beside the solar compass, are a surveying chain 38 feet long of 50 links, and another of smaller wire as a standard to be used for correcting the former, as often at least as every other day; also 11 tally pins made of steel, telescope, targets, tape measure, and tools for marking the lines upon trees or stones. In surveying through woods, trees intercepted by the line are marked with two chops or notches, on each side; these are called sight or line trees. Other trees near by not touched by the line are blazed on two sides, quartering toward the line; but if at some distance from the line, the two blazes should be near together, on the side facing the line. These are generally found to be permanent marks, not only recognizable for many years, but they carry with them their own age by the rings of growth around the blaze, which may at any subsequent time be cut out and counted as years; and the same are recognized in courts of law as evidence of the date of the survey. They cannot be obliterated by cutting down the trees or otherwise without leaving evidence of the act. Corners are marked upon trees, if found at the right spots, or else upon posts set in the ground, and sometimes a monument of stones is used for a township corner and a single stone for section corners; mounds of earth are made where there are no stones nor timber. At the corners the 4 adjacent sections are designated by distinct marks cut into a tree, one in each section. These trees facing the corner are plainly marked with the letters B. T. (bearing tree) cut into the wood. Notches cut upon the corner posts or trees indicate the number of miles to the outlines of the township, or, if on the boundaries of the township, to the township corners. These marks afford to those who are travelling through wild territories exact knowledge of their position.—A useful text book is the "Treatise on Land Surveying" of W. M. Gillespie (8th ed., New York, 1861).

SURVILLE. See **CLOTILDE DE SURVILLE.**

SUSA (Gr. *σα Σουσα*, the city of lilies), an ancient city of Persia, the Shushan (Heb., lily) of the Scriptures, the capital of the province of Susiana, and one of the residences of the court. It was on the E. bank of the Choaspes, enjoyed a fine climate, and was one of the largest cities of the Persian empire. Strabo says it was 120 stadia in circumference, and surrounded like Babylon with a wall of burnt brick. According to Æschylus and Pliny, it was founded by Darius Hystaspia, though others make Tithonus, the father of Memnon, its founder. It was for a long period the chief treasury of the Persian empire. In 325 B. C., when Alexander visited it, it possessed immense wealth, and from its plunder he gave largesses to his soldiers and presents of great value to his generals on the occasion of his marriage with Barsine and Parysatis. There has been considerable controversy on the site of the ancient city, Sus, situated at the juncture of the Kerah (Choaspes) and the Diz, and Shuster both having their advocates. The question has been definitely settled by the researches of Sir W. F. Williams and Mr. W. K. Loftus, who discovered a gigantic tumulus and numerous cuneiform and some Greek inscriptions at Sus, giving the name of one of the governors of Susiana, and describing the completion of a palace then commenced by Darius Hystaspia. —See Loftus, "Travels and Researches in Chaldea and Susiana."

SUSIANA, an ancient province or region of Persia of great extent, but mostly a plain, bounded N. by Media and the chain of the Parachoathras, E. by the same mountains and the river Oroatis, S. by the Persian gulf, and W. by the plains of Mesopotamia and Babylonia. It thus nearly corresponded to the modern province of Khoozistan. It was drained by the Eulæus (now the Karoon), the Choaspes (Kerah), the Coprates (Abzal), the Hedyphon (Jerrahi), and the Oroatis (Tab). Its earliest inhabitants were the Elymæi, probably the Elamites of Scripture, and a portion of these still occupied it in the time of Strabo and Æschylus; the other tribes mentioned as settled in the province are the Susii, the Cissii, the Cossæi, the Uxii, and the Messabatæ. The first named were agriculturists and had their villages on the plain; the others were robbers, who made their homes in the mountains, and descended to the plain only to plunder the more peaceful inhabitants.

SUSO, **HEINRICH**, often called **AMANDUS**, a German mystic, born in Constance probably in 1800, died in Ulm, Jan. 25, 1865. He entered the order of Dominicans in his 18th year, and received the degree of doctor at Cologne. From his 18th to his 40th year, in his cloister on the lake of Constance, he submitted to the severest mortification. His penance threatened to be fatal, when he threw his instruments of torture into the lake, and set out as a preacher through Swabia, Switzerland, and the valley of the Rhine.

His sympathetic character and mystical teachings gave him influence especially over women, and occasioned scandal. He has been called a minnesinger of heavenly things, and his works are, according to Görres, among the most delightful of mystical writings. Among them are an autobiography, a treatise on eternal wisdom, and a treatise on truth. Editions with woodcuts were published at Augsburg in 1482 and 1512. There is a translation into modern German by Diepenbrock (Ratisbon, 1829; 2d. ed., 1838).

SUSQUEHANNA, a river of New York, Pennsylvania, and Maryland, having its source in Otsego and Canadaga lakes, in Otsego co., N. Y. It flows in a generally S. W. direction to the Pennsylvania line in Broome co., receiving the Unadilla and several smaller tributaries in its course; near the Pennsylvania boundary it flows around the base of a spur of the Alleghanies, first a little N. of W. and then suddenly N. N. W., to Binghamton, forming what is called the "Great Bend;" after receiving the Chenango at Binghamton, its course is W. by S. till it again reaches the Pennsylvania line, where it takes a S. E. direction to Pittston, Luzerne co., receiving the Tioga and numerous small tributaries in its course; at Pittston it turns sharply to the S. W., and receives near Sunbury the large affluent known as the West branch of the Susquehanna, which is more than 200 m. in length, and to its junction with which the stream is sometimes called the North or East branch; then, turning southward, it receives the Juniata at Duncannon, 14 m. from Harrisburg, and flowing thence in a S. E. course, enters the Chesapeake bay at Havre de Grace. Its length is a little more than 400 m. from Otsego lake to the bay, and from the junction of the two branches 153 m. The river is generally shallow, and its course much broken by rapids; in the spring, during flood, rafts, and strong boats float down from Binghamton, but at other times it is not navigable. Immense quantities of timber are transported upon it. Canals have been constructed along its banks, on the main stream for 125 m., and on the West branch for 124 m. Its waters abound with fine fish; shad in great quantities are caught every season and exported largely. The lower waters of the Susquehanna are famous for the great abundance of ducks and other wild fowl which collect there every winter; and millions are exported to the Baltimore, Philadelphia, and New York markets.

SUSQUEHANNA, a N. E. co. of Penn., bordering on N. Y., and drained by tributaries of the Susquehanna river; area, 800 sq. m.; pop. in 1860, 86,267. The surface is very hilly, and the soil fertile and well adapted to grazing purposes. The productions in 1850 were 83,783 bushels of wheat, 287,848 of Indian corn, 50,105 tons of hay, and 1,020,578 lbs. of butter. There were 80 grist mills, 122 saw mills, 4 woollen factories, 4 iron foundries, 25 tanneries, and 2 newspaper offices; and in 1860 there

were 10,674 pupils attending public schools. Timber is abundant, and the export trade in pine lumber is very extensive. The Erie railroad traverses a few miles of the N. E. part, and the county is intersected by the Delaware and Lackawanna railroad. Capital, Montrose.

SUSSEX. I. A N. co. of N. J., bordering on N. Y. and Penn., bounded N. W. by the Delaware river, and drained by the Flatkill, Paulinskill, Wallkill, and Pequest; area, 600 sq. m.; pop. in 1860, 28,855. The Blue mountains traverse the N. and the Hamburg and Wawayanda mountains the S. part, and the remainder of the surface is very hilly; the soil is very fertile. The productions in 1850 were 459,254 bushels of Indian corn, 66,006 of wheat, 229,795 of rye, 151,011 of oats, 1,816,610 lbs. of butter, and 37,711 tons of hay. There were 13 forges, 6 founderies, 3 furnaces, 25 grist mills, 11 saw mills, 44 churches, 4 newspaper offices, and 7,196 pupils attending public schools. The Hopatcong lake is in the S. E. part, and supplies the summit level of the Morris canal; and there are several other small lakes or ponds. Franklinites, iron ore, red oxide of zinc, and other minerals are found. It is traversed in the S. part by the Morris canal and the Sussex branch of the Morris and Essex railroad. Capital, Newton. II. A S. co. of Del., bordering on Md., Delaware bay, and the Atlantic, and drained by affluents of the Nanticoke and Pocomoke rivers and other streams; area, about 1,000 sq. m.; pop. in 1860, 29,617, of whom 1,341 were slaves. The surface is almost level, and the soil fertile. The productions in 1850 were 1,180,086 bushels of Indian corn, 48,725 of wheat, 50,796 of potatoes, and 108,489 lbs. of butter. There were 29 grist mills, 60 saw and planing mills, 8 tanneries, 1 forge, 3 newspaper offices, 59 churches, and 4,874 pupils attending public schools. It is intersected by the Delaware railroad. Capital, Georgetown. III. A S. E. co. of Va., bounded N. E. by Blackwater river, and intersected by the Nottoway; area, 400 sq. m.; pop. in 1860, 10,175, of whom 6,884 were slaves. The surface is hilly, and the soil fertile. The productions in 1850 were 356,171 bushels of Indian corn, 35,133 of wheat, and 780 bales of cotton. There were 24 churches, and 249 pupils attending public schools. It is intersected by the Petersburg railroad. The value of real estate in 1856 was \$1,045,799, showing an increase of 14 per cent. since 1850. Capital, Sussex Court House.

SUSSEX, a S. E. county of England, bounded N. by Surrey, N. E. by Kent, S. by the English channel, and W. by Hampshire; area, 1,458 sq. m.; pop. in 1861, 368,648. It has two capitals, Chichester and Lewes; and the other towns of greatest importance are Brighton, Hastings, New Shoreham, Rye, and Horsham. The coast line is not much broken, the most remarkable projection being Beachy Head, which is 564 feet above the sea. A range of chalk hills, called the North Downs, crosses

the N. E. part of the county; and the South Downs, with an average height of 500 feet, and from 4 to 6 miles broad, run through its entire length nearly parallel to the sea coast. The principal rivers are the Arun, Adur, Ouse, and Cruckmere. The county is purely agricultural, and wheat and hops are the chief crops. The downs are principally used for pasturage, and are famous for the quality of the mutton fed upon them. Sussex is remarkably rich in antiquities, and contains many noble mansions. It returns 18 members to parliament, 2 each for East and West Sussex, and 14 for boroughs.

SUTHERLAND, a N. county of Scotland, bounded N. by the Atlantic ocean, E. by Caithness and the North sea, S. by Ross and the frith of Dornoch, and W. by the Minch; area, 1,754 sq. m.; pop. in 1861, 25,208. Dornoch, the capital, is the only town. Several small islands which lie off the N. and W. coasts are included in the county. On these sides the coasts are generally high and bold, and are indented by numerous arms of the sea; but that on the E. is flat with a low sandy beach. The interior is mountainous, the highest summit reaching the height of 3,280 feet above the sea. The rivers are all small with short courses, but there are numerous lakes. The principal crops raised are oats, barley, and potatoes. Sheep farming is extensively carried on. Game, more particularly deer, is abundant.

SUTLEJ, or **SUTLEDGE,** a river of Hindostan, the most easterly of the five rivers of the Punjab. It has its rise in some lakes in Thibet N. of the Himalaya mountains, about lat. 31° 8' N., long. 81° 58' E., and in the early part of its course is joined by numerous tributaries. In about lat. 30° 10' N., long. 75° 10' E., after a course of 550 m., it unites with the Beas, and the river from thence is called the Ghara until its junction with the Chenaub, 300 m., when it takes the name of Punjnd, and joins the Indus after a further course of 60 m., in lat. 28° 40' N., long. 70° 35' E. The upper Sutlej is supposed to be the Hesudrus and the lower the Hyphasis of the ancients. In the upper part of its course the Sutlej is an impetuous torrent, and the scenery magnificent.

SUTTEE (Sans. *sati*, from *sat*, pure), properly, a chaste and virtuous wife, but commonly used to designate the self-immolation of a widow by burning or burying alive, in connection with the dead body of her husband. The practice of suttee has existed for many centuries not only in India but in other Asiatic countries. Diodorus Siculus gives an instance which occurred in the army of Eumenes more than 300 years B. C., and in India there is reason to believe it was practised as early as the 14th century B. C. It was more prevalent there than elsewhere, from the belief encouraged by the Brahmins, and professedly derived from their most sacred books, that it conferred the highest merit not only on the widow herself, but on her dead husband. It was asserted by the Brahminical writers that every woman who

thus burned herself should remain in paradise with her husband 8 crores and 50 lacs of years (85,000,000), while otherwise she would have no place in paradise. Recent examinations of the Vedas and the Institutes of Manu by eminent philologists show that these works contain no command for suttee, and that the passages formerly quoted by Brahmins in favor of it were in some instances exactly the reverse of what the Brahmins represented. The practice was very prevalent in India long after the East India company came into power there. The Mohammedan emperor Akbar had prohibited it in the 16th century, but probably without much effect. In 1813 the company undertook to regulate the practice by prohibiting the wife from being burned separate from the body of her husband, and also from sacrificing herself with the body unless she did it voluntarily. This did not materially diminish the number of cases, for in the 13 years between 1815 and 1826 there were 7,154 officially reported in Bengal alone. In 1829 Lord William Bentinck, then governor-general of India, enacted a law declaring all aid, assistance, or participation in any act of suttee to be murder, and punishable as such. This law, at first applicable only to Bengal, was soon extended over all the company's territories, and wherever possible incorporated in the treaties made with the native princes. This created much excitement at first in Bengal, the Brahmins denouncing it with great violence as an interference with their religion, and even sending an agent to England with a large sum of money to procure its repeal. The powerful influence of Rammohun Roy was exerted against the practice, and the excitement soon subsided. Suttee is still occasionally, though rarely, practised in some of the subsidiary governments of India.—The mode of performing it was much the same throughout India, varying only according to the rank of the parties or the customs of each province. Sometimes the widow was buried alive by the side of the corpse, but generally the self-immolation was by burning. The widow, seating herself by the side of her husband's body, had the sides of her feet painted red, and then bathed herself, and dressed in her finest clothes. Meantime a drum was beaten through the adjacent villages to indicate the sacrifice that was to take place. A large company having assembled, a hole was dug in the ground, and a bed formed of green boughs, on which was reared the funeral pile of dry fagots, hemp, clarified butter, and other combustibles. The widow then gave her ornaments to her friends, painted her forehead, tied red cotton round her wrists, put two new combs in her hair, and when the body of her husband was placed upon the pile, walked around it 7 times, scattering parched rice and cowries, and finally ascended the pile, to which she was secured with ropes. The eldest son, or the head man of the village, usually lighted the pile.

SUTTER, a central co. of California, bound-

ed S. W. by the Sacramento and E. by Feather river; area, 625 sq. m.; pop. in 1860, 8,390. The surface is in some parts mountainous, and in the N. is the remarkable group of peaks called the Buttes; the soil is fertile. The productions in 1858 were 82,300 bushels of wheat, 308,000 of barley, 28,000 of oats, 3,000 tons of hay, 85,000 lbs. of butter, and 25,000 of wool. Capital, Yuba City.

SUTTON, Amos, D.D., an English missionary, born at Sevenoaks, Kent, in 1798, died in Cutch, India, Aug. 17, 1854. He studied theology under the Rev. J. G. Pike, secretary of the general Baptist missionary society, was ordained as a missionary at Derby in 1824, and was sent to Orissa, India. He remained in the missionary work for 30 years, visiting England and America once in that period. He preached in English and in Oriya, though for some years he had not the charge of a mission church; he was tutor in the mission academy and superintendent of the society's asylums for orphans, and translated the whole Scriptures into Oriya, revising the New Testament a second time. He also compiled and published an Oriya dictionary, grammar, and lesson book, wrote 3 volumes of tracts in that language, and translated 13 English works, school books, and religious treatises into it, for the use of his scholars and converts. In English he published "The Family Chaplain" (2 vols.), "Narrative of the Mission to Orissa," "Orissa and its Evangelization," "Hymn Book for Mission Congregations," "Guide to the Saviour," and one or two smaller works.

SUWANEE, a N. co. of Florida, intersected by the Suwanee river; area, about 750 sq. m.; pop. in 1860, 1,388, of whom none were slaves. There are 2 or 3 small lakes and several swamps. Capital, Suwanee.

SUWAROFF, ALEXANDER VASILIEVITCH, count, Prince Italiyski, a Russian field marshal and generalissimo, born in Moscow, Nov. 13, 1728, died in St. Petersburg, May 18, 1800. He was of a Swedish family who had emigrated to Russia in 1622. He entered the army at the age of 18 as a cadet, attained the rank of lieutenant-colonel in 1757, at the commencement of the war with Prussia was appointed commandant of Memel, and in 1759 distinguished himself at the battle of Kunersdorf. In 1763 the empress Catharine II. gave him a commission as colonel of the Astrakhan infantry, and his success in defeating the confederates of Bar in Poland, in 1768 and the following years, made him major-general. In 1773, serving under Field Marshal Rumiantzoff, he defeated the Turks in 8 battles, and, after a junction with General Kamenskoi, gained a most decisive victory over the Turkish commander at Kosludgi, and was appointed general of division. During the peace which followed, he was engaged in appeasing the troubles among the peasantry in the interior of Russia. He subsequently subdued to the Russian sway the khan of the Crimea and the Nogai Tartars, compelling

the latter, in 1788, to render homage to the empress, for which service Catharine made him general-in-chief. He again led an army against the Turks in 1788, and raised the siege of Kinburn, took Otchakov the following summer, defeated Mohammed Pasha at Fokshany, and on Sept. 22 routed the main army of the Turks on the banks of the Rimnik, for which he received the title Rimnikski, and that of count of the empire. He next laid siege to Ismail, which long withstood his forces, and was at last carried by assault, though the Russians were twice repulsed with terrible loss. Suwaroff gave it over to plunder, and 30,000 Turks were massacred and 10,000 made prisoners. At the peace of Jassy he was made governor of Ekaterinoslav, the Taurida, and the conquered provinces at the mouth of the Dniester. In 1794 he was ordered to put down the insurrection in Poland; and after defeating Kosciuszko he carried Praga (one of the suburbs of Warsaw) by assault, deluging it with blood, and entered Warsaw Nov. 9, 1794. For this service the empress made him field marshal and lavished costly presents upon him. Paul I. on his accession was prejudiced against him and stripped him of his rank; but in 1799, at the request of the emperor of Germany, he confided to him the command of the allied army sent to Italy against the French. Here he gained some advantages at Cassano, defeated Macdonald upon the banks of the Trebia, and Joubert at Novi, but was driven out of Switzerland by Masséna. He was recalled to Russia, and the title of Prince Italiyski conferred upon him; but before he could reach the capital the insane monarch had become offended with him for a trifle, and recalling all the preparations made for his triumphal entry into the capital, publicly disgraced him. The chagrin which this treatment caused the old soldier, already broken in health, led to his death. In 1801 the czar Alexander caused a statue to be erected to his memory in the Champ de Mars of St. Petersburg. His autobiography has been published under the title of *Vie de Souwaroff tracée par lui-même, ou collection de ses lettres et de ses écrits*, edited by Serge Glenka (2 vols, 8vo., Moscow, 1819), and 10 or 12 memoirs have appeared in Russia and elsewhere.

SWABIA, or SUABIA (Ger. *Schwaben*), a duchy of the German empire during its earlier period, and subsequently one of its 10 great circles, or great divisions. The circle was bounded N. by the Palatinate of the Rhine and Franconia, E. by Bavaria, S. by Switzerland, and W. by France, the Rhine flowing on the borders of the two latter. It had an area of 13,000 sq. m., and a population of 2,200,000, and was conterminous with the modern divisions of Württemberg, the southern part of Baden, and the province of Swabia and Neuburg in Bavaria. The country, one of the most beautiful and fertile tracts in Germany, is traversed by the Danube from S. W. to N. E., and diversified by the mountain scenery of the Black Forest on the W. and the Alps on the S.

It was originally called Alemannia, and received the name of Swabia (from the Suevi, who inhabited parts of it) when the Alemanni were conquered by Clovis in 496. Columba, an Irish monk, introduced Christianity in the 7th century. Toward the end of the 11th century it was in a very flourishing condition, and in 1080 the emperor Henry IV. made the duchy of Swabia hereditary in the family of Frederic of Hohenstaufen. It subsequently became one of the most powerful and most civilized countries of Germany. In the Italian wars the reigning house of Swabia stood at the head of the Ghibelline party, and when Conradin was executed at Naples in 1268 the line became extinct. The various cities, prelates, and counts then made themselves independent, and since that time Swabia has not formed a separate state. Various confederacies, however, were formed at different periods, known in history under the name of Swabian unions. The principal of these was the "great Swabian union" of 1488. The Swabian circle was definitely organized in 1563.

SWAIN, CHARLES, an English poet, born in Manchester in 1803. His father dying early, his education was superintended by his maternal uncle, a French gentleman named Tavaré, who subsequently took him into his own business, that of a dyer. When about 30 years of age Mr. Swain exchanged this occupation for that of an engraver, in which he still continues. His first literary productions appeared in the periodicals, and in 1828 he published a volume of "Metrical Essays," followed by "Beauties of the Mind" (1831) and "Dryburgh Abbey" (1832), an elegy on Sir Walter Scott, which elicited the favorable comments of Southey. His subsequent publications comprise "A Memoir of Henry Livensedge" (1835); "Rhymes for Childhood" (1846); "Dramatic Chapters, Poems, and Songs" (1847); "English Melodies" (1849); "Letters from Laura d'Auverne," &c. They have had considerable popularity in England, where the author is known as the "Manchester poet," and a collection of his poems has recently appeared in the United States (32mo., Boston, 1858).

SWAIN, DAVID LOWRY, an American statesman and educator, born near Asheville, Buncombe co., N. C., Jan. 4, 1801. He was admitted to the bar of North Carolina in 1823, and soon entered upon a lucrative practice. In 1824 he was elected to represent Buncombe co. in the house of commons, and in 1831 was appointed one of the judges of the superior court. In the succeeding year he was chosen governor of the state, being the youngest man that ever filled that office in North Carolina. Upon the expiration of his term of office in 1835, he succeeded Dr. Caldwell as president of the university of North Carolina, a position which he still occupies (March, 1862).

SWAINSON, WILLIAM, an English naturalist, born in Liverpool, Oct. 8, 1789. He served in the Mediterranean in the army commissariat

department from 1807 to 1815, then travelled in South America with Koster, the German naturalist, and on his return settled in London, and devoted himself to the study of natural history. In 1820 he commenced the publication of "Zoological Illustrations, or original Figures and Descriptions of new, rare, or interesting Animals," since republished in 6 vols. 8vo.; and in 1821 of a work on the mollusca, under the title of "Exotic Conchology" (4to.). He is also the author of a "Naturalist's Guide for collecting and preserving all Subjects of Natural History and Botany," &c. (1822); of numerous papers on natural history in the "Journal of the Royal Institution," "Zoological Journal," and "Magazine of Natural History;" of 12 volumes on different departments of natural history in Lardner's "Cabinet Cyclopædia," regarded as of high authority; of two volumes on the "Birds of Western Africa" and one on the "Fly Catchers," in Jardine's "Naturalist's Library" (1837-'8); of "A Treatise on Malacology, or the Natural Classification of Shells and Shell Fish" (1840); and of a series of "Ornithological Drawings," being selections of Brazilian and Mexican birds (1834-'41). He also assisted Sir John Richardson in the preparation of that part of his "Fauna Boreali-Americana" which relates to North American birds, and in connection with Mr. Shuckard prepared in 1840 a volume on the "History and Natural Arrangement of Insects." In 1841 he emigrated with his family to New Zealand, and since his residence there has published "Observations on the Climate of New Zealand."

SWALLOW, the general name of the diurnal fissirostral birds of the family *hirundinidae*, including the swifts, many of which are called swallows. (See SWIFT.) The bill is short and weak, very broad at the base and suddenly compressed to the tip; the wings long, narrow, and acute; primaries 9 or 10, the 1st the longest; tail more or less forked; tarsi very short and weak, generally naked, and covered with scales; toes usually long and slender, with the claws moderate, curved, and sharp; the gape very wide and usually provided with short bristles. The typical genus *hirundo* (Linn.), having more than 50 species, embraces several well known, elegant swallows both in America and the old world, remarkable for their great powers of flight; their food consists of insects, which they take on the wing, usually in the neighborhood of water, with remarkable skill and grace; they drink on the wing, sweeping along the surface of the water, and often wash themselves by a sudden plunge. They fly at the rate of a mile a minute in their ordinary evolutions, but are rather awkward on the ground from the length of the wings and the shortness of the legs; they live more on the wing than any other birds, even feeding their young in the air; from the swiftness of their flight they are rarely caught by birds of prey, and are seldom hit by sportsmen; their sight

is very acute; they fly low in damp weather, where the insects are most abundant, and are thence supposed to foretell rain. They are most numerous in the tropics, migrating to and from temperate regions in warm and cold weather; in Great Britain they make their appearance from Africa, where they spend the winter, from the beginning to the middle of April, and depart toward the end of October, crossing the channel singly or in small parties, and are as much exhausted by the passage as other migratory birds of inferior powers of flight; they often alight on vessels, and sometimes fall into the sea. In the United States they arrive about a month later and depart several weeks earlier. Most species prefer the neighborhood of man, building their nests in society in his dwellings and buildings; they form attachments to places, returning year after year to the same nests; though declared by ancient writers to be one of the two untamable animals (the fly being the other), they are docile and have been partially domesticated; they are useful to man in destroying insects, a single bird probably collecting about 1,000 in the course of a day. The nests are generally made of clay or mud mixed with straw and grass, of various forms, and attached externally to some building; many species breed in holes in sand banks, at the end of which is the nest of grasses and feathers; the eggs are 5 or 6. Swallows are alluded to in the sacred and ancient writings, and are the subjects of many strange tales and fabulous stories; they are generally considered the friends of man, and it is thought barbarous and unlucky to kill them; they are regarded as the winged heralds of summer.—The best known species in the old world is the chimney or house swallow (*H. rustica*, Linn.); it is 6½ inches long, bluish black above, with a band on the chest, and the forehead, eyebrows, and throat, ruddy; lower parts rufous white, with a white spot on the inner web of each tail feather except the 2 innermost; the tail is very long and forked. As its name imports, it frequently builds its nest in chimneys a few feet from the top; it also nests in old walls and shafts of mines, and among the rafters of barns and sheds; the nest is cup-shaped, made of earth and straw and lined with feathers; the eggs are white, spotted with ash and red. The parents are very attentive to the young, and brave in their defence; they have 2 broods in a season, the 2d sometimes left to perish, not being able to quit the nest at the period of migration, and the instinct which prompts to the latter being stronger than parental love; the males are sweet singers, and very courageous. The analogue of this species in America is not the one commonly called chimney swallow with us (which is a swift), but the barn swallow (*H. rufa*, Vieill.); it is about 7 inches long and 13 in alar extent; glossy steel blue above, with concealed white in middle of back; it much resembles its European congener, though it has the pectoral col-

lar interrupted in the middle, while in *H. rustica* it continues across. It inhabits North America from the Atlantic to the Pacific, appearing in the southern states from the middle of February to March 1, a few at a time, reaching New England in mild seasons by the middle of May; it is welcomed as the harbinger of summer, seldom appearing before the final melting of the snow and the commencement of fine weather; as it commits no depredations on man's property, and serves him in destroying noxious insects and the teasing pests of horses and cattle, it is generally liked and protected; it is believed by some credulous people that if swallows are shot the cows give bloody milk, and that their presence in a barn prevents its being struck by lightning, concerning which Wilson says: "When the tenets of superstition lean to the side of humanity, one can readily respect them." It is gentle and easily tamed, and its twitterings are very pleasant to hear in a summer's day. The nest is made of mud or moist earth mixed with grasses, and is attached to the beams and rafters of barns and outbuildings; it is generally about 8 inches long, 6 in the greatest diameter, and from beam to outside of shell $6\frac{1}{2}$ to 4, weighing often more than 2 lbs.; the eggs are 4 to 6, small and long, white with a few spots of reddish brown; incubation lasts 18 days, both sexes assisting, and both occupying the nest at night until the young are hatched. This species collects in large flocks in midsummer on barns and sheds, telegraph wires, &c., chirping almost continually, and making short sallies in search of insects. They start for the south by the end of August or first of September, early on some fair morning; they do not fly high, and follow the shore or the course of rivers.—The cliff or fulvous swallow (*H. lunifrons*, Say) is about 5 inches long and $12\frac{1}{4}$ in alar extent; the crown and back are steel-blue, separated more or less broadly by a grayish collar; the chin, throat, and sides of head dark chestnut; breast grayish brown; belly white; steel-blue spot on throat; rump light chestnut, and forehead brownish white; tail slightly notched. It is found throughout North America from ocean to ocean; it is called republican swallow by Audubon, in allusion to the habit of associating to make their nests and rear the young. The nest is built under eaves and cornices, where it is partly sheltered from the rain; it is made of clay and sand, the entrance near the top, shaped like an earthen retort with the neck broken off; it is lined with straw and grass; the eggs are white with dusky spots; the nest is bravely defended by the parents. The white-bellied swallow or American house martin (*H. bicolor*, Vieill.) is $6\frac{1}{2}$ inches long and $12\frac{1}{4}$ in alar extent, of a glossy metallic green above and white below; it is a quarrelsome species, coming earlier in the spring than the others, but is not so common; the nest is made in a hollow tree, lined with grass and feathers, and the eggs are white with a bluish tinge; it is as widely distributed

as the others in North America, and some time before migrating southward gets very fat on myrtle berries (*myrica cerifera*). For the largest of the American swallows, see MARTIN. The largest of the genus *hirundo* is the *H. senegalensis* (Linn.), from Africa, shining black above, and ruddy on the belly and hind part of back. There are many species in the East Indies, some permanent residents, others migrating to temperate Asia. Some species usually called swallows, as those which make the famous edible nests so esteemed in the East, belong among the swifts.—The bank, sand, or river swallow belongs to the genus *cotyle* (Boie); it is the *C. riparia* (Boie), and the smallest of the American species, being 4½ inches long and $10\frac{1}{4}$ in alar extent. The bill is very flat, and extremely wide at base, gradually narrowing toward the tip; nostrils prominent and rounded; tail moderate, nearly even or very slightly forked; tarsi rather long, with a tuft of feathers near the toes behind. It is grayish brown above, sometimes approaching sooty, with paler margins; below pure white, with a band across the breast and sides like the back. It is generally distributed over America and Europe, wherever there is a sandy pit or river bank; it is hardy, the earliest to arrive in the spring, and less familiar than the other species; it hollows out a tubular gallery in the sand banks, often more than 8 feet in length, at the end of which is a larger excavation for the nest; it is called sand or bank martin in Europe. There is no appreciable difference between the European and American birds, furnishing one of the very few instances (perhaps the only one) among land birds of the same species permanently inhabiting both continents. In the rough-winged swallow (*C. serripennis*, Bonap.; *stelgidopteryx* of Baird), the 1st primary has the outer edge converted into stiffened recurved hooks, and the tarsus is without feathers.—In the genus *chelidon* (Boie) the tail is moderate and forked, and the tarsi and long toes are clothed with downy feathers; it is peculiar to the old world. The European window swallow, house martin, or martlet (*C. urbica*, Boie) is 5 inches long, black above, and white below and on rump; it has the same habits as the common swallow, with a less rapid but more sweeping flight; it is more familiar, breeding even in cities; the nest is always on the outside of buildings, under the eaves or projecting parts; the eggs are white; it has no song.

SWAMMERDAM, JOHANNES, a Dutch entomologist and physician, born in Amsterdam in 1687, died in 1681. He studied medicine with his father, who was an apothecary, and at the university of Leyden. While occupied with his other studies he gave considerable attention to the natural history of insects, and made many dissections and microscopical examinations and a large collection of specimens. He obtained leave at Amsterdam to dissect the bodies of those who died in the hospital, and invented the mode for the preparation of hol-

low organs now usually employed in anatomy. He published a "General History of Insects" (1668); "The Natural History of Bees" (1678); and a "History of the Ephemeras" (1675). His entomological collection was divided at his death and sold in small portions to different purchasers. Boerhaave, who edited his works and wrote his life, esteemed his "History of Insects" incomparably superior to any thing that had preceded it. An English translation of his entomological works by T. Floyd was published in 1758.

SWAN, a well known web-footed bird of the duck family, and the type of the sub-family *cygnina*, embracing some of the largest and most graceful of aquatic birds. The bill and feet are much like those of the ducks, the former being stout, of nearly equal width throughout, and with a comparatively small nail; the neck very long, and the legs short; wings long and powerful, 2d and 8d quills equal and longest, a blow from them having been known to break a man's arm; tail short and rounded; eyes small and near the bill. They perform long migrations, flying in single files uniting at an acute angle; the diet is chiefly vegetable, consisting of grass, roots, and seeds, in search of which they submerge the head only, keeping it under water 8 to 5 minutes at a time; they also devour aquatic worms and insects, young frogs, and probably small fish; the intestines are long, as in the vegetable feeders; they are gregarious at all seasons of the year, awkward on land, but rapid and high fliers; they are remarkably careful to keep their plumage, which is generally white, free from dirt of all kinds. The nest is bulky, of grass and coarse materials, placed on the ground among the rushes and near the water; it is sometimes raised a foot or more to avoid inundations; the male guards the nest, assists the female in the care of the young, and boldly defends them even against predaceous animals and man; the eggs are 5 to 8, and incubation lasts 6 weeks.—In the typical genus *cygnus* (Linn.) the bill is longer than the head, the base covered by a soft skin extending to the anterior half of the eyes, and the nostrils in the middle portion; lower part of tibia bare; tarsus much shorter than the foot, compressed and scaly; webs full; hind toe small, much elevated, with a narrow lobe; tail of 20 to 24 feathers, rounded or wedge-shaped; sexes similarly colored, but the females the smallest. Wagler has divided the old genus *cygnus* into two, *cygnus* and *olor*, according as there is or is not a swollen fleshy tubercle at the base of the bill; in the former also the lamellæ of the edges of the bill are visibly projecting, and in the latter not; in the former belongs the tame swan of Europe, and in the latter the wild swan and both the North American species. The European wild or whooping swan (*C. ferus*, Ray) is 4½ to 4¾ feet long, white, with the head and neck tinged with yellowish, and a black bill, yellowish at the base and without tubercle; it is a winter

visitor in Great Britain, migrating northward in the spring to Lapland, Russia, Siberia, &c., where it breeds; the young are brownish gray. The male has a peculiar note resembling the word "hoop," repeated several times in succession, the intensity greatly increased by the convolutions of the windpipe, which, after penetrating the keel of the breast bone to its posterior portion, is bent forward again to the front of this bone before going to the lungs; this anatomical peculiarity is not found in the tame swan, which has a soft and plaintive voice. Though praised by the poets for its gentleness and beauty, it is cruel and vindictive, the males fighting savagely at pairing time, and the female with young attacking every thing which approaches her nest; it can repel any bird, even the eagle, and in fighting the combatants try to drown one another by holding the rival's head under water, often with fatal effect. Though heavy and rather slow fliers, they rise to a great height, uttering a loud, harsh, and trumpet-like note when sailing high in the air; when enraged or alarmed they can swim faster than a man can walk. This bird was sacred to Apollo, and was the bird of the Muses; it was strangely celebrated for its melodious song, especially at the time of its death; the sound of its wings at a distance is loud and not unmusical, and even its harsh scream may appear pleasant to the Icelanders and other northern nations, as the flocks arrive in the spring, announcing the end of the dreary winter; but as far as southern Europe is concerned, its song is a mere fable. The flesh is dark and tough, and, though prominent at ancient feasts, was probably more for ostentation than consumption.—The European tame swan (*C. olor*, Gmel.) has a red bill, with black tip and sides, and a tubercle at the base; the trachea has no convolutions. It is generally distributed over Europe and America as an ornamental bird; it was well known to the ancients, and by the poets was sung as the model of grace and the bird of love, and represented as attached to the car of Venus; its flesh was served with great pomp at their public feasts. It is a large and handsome species, a permanent resident in temperate Europe; in Great Britain from remote periods it has been protected by preservative laws, whose infringement was punished by fine and imprisonment; the male is called a cob and the female a pen; its life is said to extend to a century. The young have a gray plumage and a lead-colored bill; their flesh is sometimes eaten at the present day, and when properly cooked is said to be delicious, with a flavor between that of the goose and of the hare. As an ornamental bird nothing is more pleasing than the swan, an emblem of peace, quiet, and refinement, as it swims slowly over the surface of a placid lake. The most prized are brought to the United States from Hamburg, and are generally what are called Polish swans (*C. immutabilis*, Yarr.), from the Baltic shores, noted for having white cygnets. Bewick's swan (*C.*

minor, Pall.) is a smaller, wild species, making considerable noise in its migrations, and a winter visitor in Great Britain.—The American or whistling swan (*C. Americanus*, Sharpless) is 55 inches long and about 7 feet in alar extent, with a bill of 4½ inches; the bill is as long as the head, high at the base, the feathers on the forehead ending in a semicircular outline; the nostrils far forward; tail of 20 feathers; the adult is pure white with bill and legs black, and an orange or yellowish spot in front of the eye; young birds are brownish, especially on the head; they are 5 or 6 years in coming to maturity. This species is spread over the North American continent from the Atlantic to the Pacific; many are shot in winter and spring on the coasts of Virginia, Maryland, and Delaware; they are very watchful when feeding, one always acting as sentinel; they fly in an angle, each line in single file, the leading bird as he gets weary retiring to the rear. The nest is described as made of moss, peat, and sticks, 5 to 6 feet long, 4½ wide, and 2 high, with the cavity 1½ in diameter; the eggs are brownish white, clouded with darker. The trumpeter swan (*C. buccinator*, Rich.) is about 5 feet long and 7 in alar extent, with the bill 4½ inches; bill longer than the head, the feathers on the forehead with a semi-elliptical outline; nostrils with the anterior extremity only as far forward as the middle of the commissure; tail with 24 feathers; the adults are pure white, the legs and bill entirely black, the latter without any red spot at base. It is found from the Mississippi valley to the Pacific, appearing on the lower Ohio about the end of October, and going south when the ice gets thick; it is very common in the fur countries, breeding as low as lat. 61° N. As its name imports, the note is more sonorous than in the whistling swan; it is not so wary as the last named species; as in all swans, during flight the neck and legs are stretched at full length; it is the principal source of the fine down so much prized for muffs and tippetts.—The black-necked swan (*C. nigricollis*, Steph.), of South America, has the head and neck black and the bill red. The *C. cascoraba* (Mol.), also South American, has the lores feathered.—A black swan, once considered as apocryphal as a white crow, inhabits Australia, that land of strange animals; the *chenopsis atrata* (Wagl.), of that continent and Tasmania, is black except a few white primaries and a bright red bill; it is nearly as large as the common swan, and is now not unfrequently seen with it in the parks of Europe; its dying note, far from being melodious, is said to be like the creaking of a rusty sign on a windy day.

SWAN RIVER, a river of West Australia, which, after a N. W. and S. W. course of about 180 m., in which it several times expands into small lakes, and after passing near Guilford and the city of Perth, falls into the sea by an extensive estuary about lat. 32° S. It is subject to sudden floods which are often very destruc-

tive. Swan river was first discovered in 1696 by Vlaming. In 1829 the colony now called West Australia was founded upon its banks.

SWANSEA (Welsh, *Abertawy*), a town and parliamentary borough of Glamorganshire, Wales, situated on the W. bank of the river Tawy, where it falls into the bay of Swansea, Bristol channel, 84 m. W. from Bristol; pop. in 1861, 42,581. It is much resorted to for sea bathing. There are extensive anthracite mines in the neighborhood, which, together with the convenience of the port, have caused it to be made the principal seat of the copper trade of Great Britain. Copper ore is brought from Cuba, South America, Australia, &c., to be smelted at Swansea. There are iron, tin plate, and zinc works, potteries, &c., and ship building is carried on. In 1859 there were owned here 4,773 vessels, tonnage 508,814. There are extensive docks with every convenience for loading and unloading vessels; and the first floating dock was built at Swansea in 1852. In consequence of the great height to which the tide rises vessels of large size can come close to the town at flood, but at ebb the harbor is nearly dry. Swansea is connected by railway with Milford and Gloucester, and is the terminus of the Swansea Valley railway, opened in 1860.

SWARTZ, Olof, a Swedish botanist, born at Norrköping, East Gottland, in 1760, died in 1817. He studied medicine at Upsal, and between the years 1779 and 1782 made excursions in the various districts of Sweden to study their botany, and visited Lapland, Finland, and Gottland. In 1789 he visited the western coasts of America and the West Indies, and, after spending a year in England, returned to Sweden in 1789, and in 1790 was appointed professor of natural history in the medico-chirurgical institution of Stockholm. He added upward of 50 genera and 850 species to the list of flowering plants, beside a great number to the class of *cryptogamia*. He published botanical works in Latin, wrote the text of 4 volumes of the *Svensk Botanik*, and contributed to the "Philosophical Transactions" and the "Transactions of the Linnæan Society" of London.

SWEABORG, or SVÆABORG, a fortress and military post in Finland, belonging to Russia, 3 m. S. E. from Helsingfors, the approaches to which it defends; pop. 6,000. It is built upon 7 granitic islands forming an ellipse, all of them strongly fortified, and connected either by causeways or bridges of boats; they are Vargö and Gustafsvård on the S., Wester Svartö and Langärn to the N. W., Löven and the Little Öster Svartö to the N., and the Great Öster Svartö to the N. E. The principal fort is on Vargö, and comprises a strong castle and barracks, and magazines excavated in the rock and bomb-proof. There are at some points 8 tiers of guns. The total number of cannon is 2,000, and the usual garrison of the fortress varies from 6,000 to 8,000 men, though the casemates have accommodations for 12,000. The harbor within, to which there is but one entrance, has

room for 70 ships of the line. The fortress was erected between 1749 and 1758 by Count Ehrenswerd, field marshal of Sweden (who is buried within it), as a defence against Russia. In 1808 it was besieged by the Russians, and after 2 months Admiral Cronstadt, though amply supplied with the means of defence, capitulated. Left in possession of the conquerors by the peace of 1809, it was called the "Gibraltar of the North," and has since been regarded as the strongest fortress of Russia on the Baltic. In Aug. 1855, it was severely but unsuccessfully bombarded by the allied fleet.

SWEATING SICKNESS. During the middle ages Europe was ravaged by numerous and fatal pestilences; some of these, after repeatedly decimating every considerable city in Europe, are now confined almost exclusively to Egypt and the Turkish dominions; others have completely disappeared, and left no trace except in the chronicles of the period. Among these latter was the sweating sickness. It made its first appearance in England in 1485, just after the battle of Bosworth, and disappeared suddenly at the commencement of the next year. It attacked chiefly people in the prime of life, avoiding the extremes of old age and infancy, and was so fatal that, according to Hollinshed, scarce one in 100 of those attacked escaped with life. It made a second appearance during the summer of 1506, but this time the disease was mild and manageable, so that it was thought that medicine had got the better of it; after a short time it again completely disappeared. In July, 1517, it broke out for a third time, appearing first in London. This epidemic was exceedingly fatal, often carrying off the patient in the course of a few hours, so that the shivering fit was regarded as the announcement of certain death; it lasted for 6 months, and like the preceding ones its ravages were confined to England alone. In May, 1528, the sweating sickness again made its appearance in London. This time the duration of the disease was longer, for it still lingered in England in the following summer; it was very fatal, so much so as to be denominated by some historians "the great mortality;" and finally it extended over the northern half of the continent. It first spread to Hamburg, attacking the crew of an English vessel recently arrived, and in the course of 21 days is estimated to have cut off 2,000 persons. From Hamburg it extended over all northern Germany, reaching as far south as Augsburg, and then making its way gradually to the Netherlands, Denmark, Sweden, and Norway. In 1551 the disease again appeared in England, and, after spreading alarm and death throughout the country for 6 months, finally entirely disappeared.—The sweating sickness occurred when medical science was at a low ebb, and entirely confined within the narrow limits of the Galenic theories; what accounts we have of it are mainly derived from the chronicles of the time rather than from the writings of physicians. Hecker

("Epidemics of the Middle Ages"), from whom our account has been taken, speaks of it as of a form of "inflammatory rheumatic fever;" but he must use the word in a different and much larger sense than is usually given to it. The disease commonly commenced with a chill, accompanied by an alarming prostration. Pain in the head was an invariable symptom: this was soon followed in some by delirium, in others by a lethargy which gradually lapsed into fatal coma. Early in the disease, sometimes at its commencement, the patient broke out in a copious sweat; this had an exceedingly offensive smell, and poured in streams from the patient, so that he "lay, as it were, in a stinking swamp." The pulse was quick and feeble, the breathing labored, the countenance livid, and the patient restless, constantly tossing and throwing himself about. Sometimes nausea and vomiting were present, sometimes convulsions came on; the voice was "whining and sighing;" "neither the activity of the kidneys nor the evacuation by stool was entirely interrupted." The crisis of the disease occurred commonly within 24 hours, and many died within that time; if they survived it, recovery gradually took place; but the patient was left in a very feeble condition, and the convalescence was tedious and protracted. Relapses were common, even to a 3d and 4th attack; in these cases organic changes probably took place, for the patients are said to have died of dropsy or some other incurable affection. The disease was probably contagious, as it seems to have followed the great channels of commercial intercourse. Its propagation was favored by the personal uncleanness, the want of ventilation in dwellings, the starvation, and the excesses common at the period; and its mortality was aggravated by the injudicious means employed for its cure.

SWEDEN (Swedish, *Sverige*), a kingdom of northern Europe, forming with Norway, with which it is politically united, the Scandinavian peninsula, and lying between lat. 55° 20' and 69° N. and long. 11° 18' 30" and 24° 13' E. It is bounded N. and W. by Norway, S. W. by the Cattegat and the Sound, S. by the Baltic sea, E. by the Baltic and the gulf of Bothnia, and N. E. by Finland. It is separated from Norway by the long range of mountains forming the main chain of the Scandinavian system, along which a broad avenue cut in the forest, and having at certain intervals stone monuments, marks the line of division. This avenue is maintained with great care and kept free from obstructions by the Norwegians, and its condition regularly reported to their *storting* or legislature. The extreme length of Sweden is 970 m., and its average breadth about 200 m. It is divided into 8 provinces: Gottland, Svealand, Swedeland, or Sweden proper, and Norrland. These are subdivided into 24 län or districts, whose extent and population were in 1858 as follows, according to the *Almanach de Gotha* for 1862:

Lane or district.	Area, sq. m.	Population in 1888.	Chief towns.
GOTTLAND.			
Malmö.....	1,799	276,509	Malmö.
Christianstad.....	2,444	201,440	Christianstad.
Blekinge.....	1,113	114,647	Carlscrona.

Total of Sweden.....	170,626	3,784,240	

Gottland (the region originally inhabited by the Goths) lies S. of lat. 58° 45', and comprises also the islands of Oland and Gottland; Svealand, the original country of the Svanakar or Swedes, is the middle region of the kingdom, extending from Gottland northward to lat. 60° 40'; and Norrland is the whole northern section up to the Norwegian frontier of Finland. —The coast line, which is about 1,400 m. in extent, is deeply indented by numerous fjords or gulfs, which penetrate far into the interior of the country; about 300 m. of the coast borders on the Skager Rack, Cattegat, and Sound; the remainder is washed by the Baltic and the gulf of Bothnia. The W. shore along the Skager Rack and Cattegat is rocky, but seldom elevated more than 30 or 40 feet. The S. shore as far as Solvitsborg in Blekinge is low and sandy; thence northward it is, with some exceptions, lined by precipitous cliffs about 50 feet in height as far as Ölmar sound, lying between Oland and the mainland. The bay of Carlscrona makes a deep indentation in this portion of the coast. Along the Sound the coast is again low and sandy, but north of it rises into higher cliffs, and at the outlet of Lake Mälmar presents bold headlands 100 feet in height. Above the mouth of the Dal and as far as the strait of Quarken the rocky and sandy shores alternate; while the upper part of the gulf of Bothnia is characterized by low sandy beaches. The rivers are numerous, and mostly of rapid current. The principal are the Tornea, 290 m. long, and with its affluent the

Muonio forming the boundary between Sweden and Finland; the Lulea, Pitea, Skelleftea, and Umea; the Angerman, a broad and deep stream 230 m. long, and navigable for vessels of 600 tons 70 m. from its mouth; the E. and W. Dal, which uniting form the outlet of several lakes; these all fall into the gulf of Bothnia. The Klar and the Göta discharge their waters into the Cattegat. The Trolhätta fall on the latter is celebrated; the quantity of water is very large and the descent 112 feet. Sweden abounds in beautiful lakes; over 80 are enumerated. The largest is Lake Wener, 90 by 56 m. in extent, and the largest lake in Europe except Lake Ladoga. Lake Wetter is smaller, but has an area of nearly 720 sq. m., and receives 40 rivers. Lake Mälmar is an arm of the sea, with beautiful banks, and contains, it is said, 1,400 islands. The other principal lakes are the Hjelmar, connected with Lake Mälmar; the Silja, the Storjan, the Horn-Afvan, and the Stora-Lulea-Watten, in which the Lulea river has its source.—The mountain chain which forms the spine of the Scandinavian peninsula, and which is collectively known as the Dovrefield or Dofrinea, has a much larger portion of its most elevated surface in Norway than in Sweden. Its lower portion, the Langfield chain, is wholly in Norway, while the Dovrefield and Kiölen chains form the boundary between the two countries; their loftiest summits, Sulitelma in lat. 67° and Sylfjellen in lat. 63°, lie partly in each. The western or Norwegian side of these mountains has a much more precipitous character than the eastern or Swedish. In Sweden they form a plateau nearly 4,000 feet high, from which occasional peaks rise to a greater height, but which in a breadth of 40 m. slopes gradually to an elevation of from 800 to 1,000 feet, and thence declines in hills of moderate elevation to the sea shore. S. of lat. 59° the country is very level, and the great plain of Scania, the most fertile tract of the peninsula, occupies a considerable portion of the southern extremity. The northern part of Sweden is rocky, with bleak, barren, snow-clad hills, and a stunted vegetation of birch, fir, and small pines, in the higher lands intermingled with dreary lakes and swamps. The great forest region lies S. of lat. 64°, where the surface is less elevated. It is computed that $\frac{1}{4}$ of the territory of the kingdom is covered with forests. Further S. the surface is more level, and the woods give place to cultivated fields.—The geological formations of Sweden are in chief part granites, gneiss, and metamorphic rocks. They compose most of the Scandinavian chain of mountains, and are in many places covered with silurian strata, which sometimes are seen undisturbed from their original horizontal position. These are broken through and overflowed by trap; and the surface is generally covered with the drift formation and large bowlders. The metamorphic group abounds in metallic veins which constitute a large portion of the wealth of the country, and are productive in a great variety of

metals, as iron, copper, lead, zinc, silver, cobalt, &c. The pyritiferous slates are largely worked for alum and copperas, and these, as well as the sulphurous gangues of the various ores, might be made to furnish unlimited supplies of sulphur. The production of the metals is variously given by different authorities, and has been noticed in the tabular statement in the article *MINE*, as also to some extent under the heads of the different metals. The localities of the most important mines are: of iron, at Dannemora in the län of Upsal, and in Wernmland, Örebro, Gefleborg, Kopparberg, and Westmanland; of copper, at Falun in Kopparberg, and at various other places in the läns of Östergötland, Jämtland, Westmanland, &c.; and of silver at Sala, in Westmanland. It is stated that the silver mine at this place in 1850 produced 805,000 oz. of silver. Coal of inferior quality is found in the S. part of Sweden, near Helsingborg. An interesting geological change in the coast line of Sweden, caused by the gradual rising of the land, has been noticed as taking place ever since it was first observed by Celsius in the early part of the last century. By him it was attributed to the depression of the waters of the Baltic. The greatest movement is noticed along the N. coast, and has been rated at about 6 inches in 100 years. It is much less at Stockholm, and gradually decreases further south.—The soil of Sweden is not generally very fertile, much of it being produced by the disintegration of primitive rocks, and containing a large proportion of silex. There are nearly 4,000 sq. m. of arable lands, and somewhat more than 7,000 of meadow lands and pasturage, so that in all not far from $\frac{1}{2}$ of the surface of the kingdom is under cultivation. The climate of the Scandinavian peninsula is generally milder than that of other countries in the same latitude; the E. is about 2° colder than the W. side, but the winter is 5° warmer and the summer 1° colder. In the S. there are scarcely 5 months of rigorous winter, and the general temperature of this section differs but little from that of the N. of France or of N. Germany. At Stockholm, in lat. 59° 20', the mean annual temperature is 42°, that of winter 25° and of summer 62°; at Lund, lat. 57° 42', the annual mean is 45°, that of winter 29.54° and of summer 62°; in Falun, lat. 60° 39', the annual mean is 40°, that of winter 22° and that of summer 58.88°; and in Enontekiä, lat. 68° 30', and at an elevation of 1,440 feet, the annual mean is 27°, the winter temperature 1.49° and the summer 54.61°. In Swedish Lapland there are scarcely 2 months of summer, which has been described as follows: "On June 23 the snow begins to melt; on July 1 it disappears; on the 9th the fields are covered with grown grass; on the 17th grain crops are in full growth, and on the 25th in full flower; on Aug. 2 fruits are ripe; on the 9th harvest is over; and on the 18th it snows." In Norrland, in the space of 9 weeks, hay will have been cut twice and the year's seeding and harvest completed. At Stockholm

the longest day is 18½ hours and the shortest 5½ hours. At Tornea, 21½ hours is the longest; and at Enontekiä, lat. 68° 30', the sun remains above the horizon about 3 weeks.—The pine and fir forests of Sweden furnish a great abundance of timber, which is largely exported for building and shipping purposes. In the middle province there are also considerable quantities of ash, linden, willow, maple, and the weeping birch, one of the most beautiful of northern forest trees. In the southern province the oak attains great size and beauty, and the beech and elm are common. With the exception of the cherry there are few fruit trees N. of the 60th parallel. Barley is cultivated in all parts of Sweden, and rye, wheat, oats, beans, peas, and potatoes are successfully grown in the middle and southern provinces. The gooseberry grows as far N. as 70°. Tobacco is raised in the vicinity of Stockholm. Root crops are largely cultivated.—The fauna of Sweden is not as numerous as of some of the other northern countries of Europe. The principal quadrupeds are the brown bear, wolf, lynx, fox, glutton, lemming, deer, elk, marten, hare, sable, beaver, and squirrel. The birds are more numerous, sea fowl especially seeking the sheltered coasts of the Baltic and gulf of Bothnia. The eagle and falcon, the wild goose, eider duck and other species of wild ducks, swans, and the gull tribe abound; and on the heaths the woodcock, capercaillie and other grouse are plentiful. Among fishes, the herring, or rather the *strömming*, an allied genus, are plentiful on the S. coast, and the turbot, oyster, lobster, salmon, and trout are found in great numbers in the seas and rivers. The domestic animals are mostly of small size, and, though hardy, the cattle and sheep are of inferior quality. In the north the reindeer and dog are used to some extent for draught.—The Swedes are a branch of the old Scandinavian or Norse stock. They constitute the greater part of the population, though the districts of Westerbotten and Norrbotten are principally inhabited by Finns and Lapps, who together number about 150,000. The Swedes are, like the other Scandinavian races (the Danes and Norwegians), tall and of a sandy or florid complexion, and powerful *physique*. They are divided into 4 classes, the nobility, clergy, burghers, and peasants. The Swedish aristocracy is among the oldest in Europe, and now consists of about 2,400 families, numbering in all nearly 11,000 persons. They were formerly very wealthy, and possessed $\frac{1}{2}$ of the landed property of the kingdom; but many of them are now very poor, though their pride is such that they will not compromise themselves by engaging in commercial or industrial pursuits. They are the principal officeholders of the realm. The clergy number with their families about 15,000 persons; 1,800 are beneficed clergymen, and about 1,900 professors, teachers, or assistants to the pastors. The class of burghers comprises about 70,000 persons, and are members of the various guilds, or iron manu-

facturers, or have been parochial magistrates; they hold real estate of the value of about \$15,000,000. The peasants comprise about 2,800,000 of the population, and possess landed property to the amount of about \$75,000,000. They are industrious, prudent, and well educated, and are gradually absorbing the landed property of the kingdom, especially that from the encumbered demesnes of the nobility. There is also a class belonging to neither of these estates, comprising nearly 900,000. The Swedes are an enterprising, energetic, and thrifty people, but have hitherto been addicted to some vices which have seriously marred their character. Drunkenness, from immoderate potations of their fiery corn brandy, has been more common than in any other country in Europe, and was productive of a large amount of crime; but there has been a great improvement in this respect in the last 13 years. Owing to the religious excitement propagated by the *Läsare* or Readers and other dissenting sects, and the formation of numerous temperance societies, intemperance has greatly diminished, and crime with it. The consumption of distilled spirits, which in 1840 was over 80,000,000 gallons, and in 1850 nearly 40,000,000, had diminished in 1861 to about 10,620,000 gallons. Illegitimacy has been fearfully prevalent in Sweden for many years. Houses of prostitution were not suffered to exist; but unchastity, or at least indifference to marital obligations, prevailed to such an extent that in 1849 in Stockholm the proportion of illegitimate to legitimate births was as 1 to 2.27; in other towns as 1 to 5; in the whole kingdom as 1 to 11. In this respect, too, it is said that the past few years have witnessed a decided change for the better.—More than $\frac{1}{3}$ of the population are engaged in agricultural pursuits, a considerable number in navigation and commerce, and a small body, mostly from the burgher class, in manufacturing and trade. During the past 40 years Sweden has made a great advance in agriculture. The government has done much to encourage it, and the establishment of agricultural schools and model farms, and the introduction of improved implements, have been of great service. Though the soil is sterile and yields grudgingly, and so much of it is still covered with the primeval forests, yet the cereals, formerly articles of import, are now exported in considerable quantities; in 1858 this export (principally of oats and barley) reached the amount of 4,300,000 bushels. Barley is raised in all parts of the kingdom, rye to the 66th, oats to the 64th, and wheat to the 62d parallel of latitude. There is an abundance of pasture for cattle, sheep, and goats in the summer, but the long winter requires them to be so long housed as materially to diminish the profit of raising them. In 1855 there were 1,921,568 horned cattle, 1,792,070 sheep, and about 400,000 horses in the country.—Sweden has made great progress in manufacturing industry within the past few

years. While the number of distilleries, of which in 1835 there were 85,172 small and 670 large ones, had diminished in 1858 to 2,478 small and 826 large ones, and has since still further decreased, other branches of industry have greatly increased. There are 2 very large manufactories of steam engines, iron steamers, &c., one at Motala employing 800 men, and another at Norrköping employing 400; and extensive saw mills, paper mills, cutlery shops, and manufactories of cotton, woollen, linen, and silk stuffs, sail cloths, hardware, glass, earthenware, clocks and watches, &c. The amount of goods produced in the registered manufactories of the country in 1839 was \$5,498,128; in 1850, \$9,891,072; in 1854, exclusive of the engine works, saw mills, and paper mills, over \$11,841,618; in 1855, \$14,487,645. These amounts include none of the homespun fabrics so largely produced in Sweden, and which rival in fineness and beauty those of the registered factories. The district most remarkable for these is Elfsborg, containing 261,850 inhabitants, and which produced in 1855, over and above the quantity consumed by them, 9,047,506 yards of cotton cloth, 1,568,556 cotton handkerchiefs, 260,000 yards of linen cloth, and 392,425 yards of woollen goods. In Geseborg, containing but 181,986 inhabitants, 1,384,666 yards of heavy linen cloth were produced in the families.—There has been great confusion in regard to the money, weights, and measures of Sweden, which has recently been terminated by the adoption of a decimal system, passed by the diet of 1854 and put in operation Jan. 1, 1858. The unit of money has been from time immemorial the *rikdaler* (government dollar). The various wars prior to 1815 depreciated the Swedish paper money greatly, and the government notes were of less value than those issued by the bank, which was an independent institution, though under the management of directors appointed by the legislature. The specie dollar was 106 cts., the *riksgald* (royal debts) dollar 26 $\frac{1}{2}$ cts., or 4 to the specie dollar; while the *rikdaler banco*, or bank dollar, was 39 $\frac{1}{2}$ cts., or $\frac{3}{4}$ of the specie dollar and 1 $\frac{1}{4}$ of the *riksgald*. The *rikdaler banco* hence became the official money of accounts. All three (the specie, banco, and *riksgald*) were divided into 48 *skillings*, and the skilling into 12 *rundstycke*. The new currency adopts the *riksgald* dollar (26 $\frac{1}{2}$ cts.) as the unit, calling it the *riksmynt* dollar, and divides it into 100 *öre*. All future accounts are to be in this money, and the currency for foreign coins will be quoted in *riksmynt* money at so much per 100 of the foreign coins, except the pound sterling, which is quoted per £. The silver coins, which are 8 parts silver and 1 copper, are in pieces of 1, 2, and 4 *riksmynt* dollars, and pieces of 10, 25, and 50 *öre*. In weights a similar reform has taken place, the Swedish pound or unit of weight being 0.937 of an English pound. In length, 100 English yards (= 300 feet) contain 308 Swedish feet, or 1 English foot equals

1.026 Swedish. One English acre contains 4.59 Swedish *quadrattref*; one gallon 1.446 *kans*; 1 bushel 1.762 Swedish cubic feet. The Swedish mile is equal to 6.8285 English miles.—The commerce of Sweden has been increasing in importance for some years past, the injurious restrictions formerly imposed upon it by the government being removed. The following table gives the imports and exports for the 5 years ending with 1859:

Years.	Imports.	Exports.	Total.
1855.....	\$23,694,000	\$25,559,300	\$48,153,300
1856.....	23,225,300	24,648,800	52,874,000
1857.....	34,116,000	31,369,800	65,485,800
1858.....	15,068,800	15,004,260	30,063,060
1859.....	19,673,365	20,546,755	40,220,120

The trade with the United States in 1855 was: imports, \$776,400; exports, \$762,400; together, \$1,538,800. In 1859 the imports had increased to \$1,462,270, while the exports remained nearly the same. The total imports of 1859 included cotton (of which 11,662,859 lbs. was from the United States), coffee, wheat, flour, rye and rye flour, tobacco (1,848 hhds. and 430,000 cigars from the United States), sugar, tools and machinery, hides, wool, tea, &c. The exports were alum, bar and pig iron and steel (to the value from the two ports of Stockholm and Gothenburg of \$4,615,289, of which \$512,387 came to the United States direct), timber (spars or beams and plank), breadstuffs (mainly barley, rye, and oats), tar, bones, and linseed cake. The following table exhibits the growth of the Swedish commercial marine during the last 65 years:

Years.	No. of vessels.	Tonnage.	Mariners.
1795.....	721	92,000	6,271
1810.....	852	103,796	7,542
1820.....	819	103,630	6,923
1830.....	1,841	144,148	7,579
1840.....	2,171	175,558	7,944
1850.....	2,744	225,966	9,283
1855.....	3,020	277,586	10,669
1859.....	3,864	314,912

This is exclusive of vessels employed in internal navigation, on the canals, lakes, &c., which in 1855 were 1,676, measuring 65,186 tons. The number of merchant steamers the same year was 181, of 5,927 horse power. There are 4 large canals in Sweden: the Götha or Göta canal, connecting the Cattegat with the Baltic, by the Göta river and Lakes Wener and Wetter, with the Trolhätta canal as a portion of it, which avoids the Trolhätta fall, having a total length of about 260 m.; the Hjelmars or Arboga canal, connecting by the Arboga river Lake Hjelmars with Lake Mælars; the Södertelge canal, connecting Lake Mælars with the Baltic; and the Stromsholms, connecting the same lake with the mineral region of Dalecarlia. The first railroad, that between Nora and Örebro, 23 m. long, was opened in 1856. There are now also lines from Dylta to Arboga, 12 m. long, between Malmö and Lund, between Stockholm and Gothenburg, and from Gefle to Falun. The whole extent of railroad lines opened exceeds 200 m.—Elementary education

is universal in Sweden. For nearly 200 years the ability to read and write has been indispensable to the assumption of the functions of citizenship. In 1842 an attempt was made to establish a school in every parish, but the northern districts are so thinly peopled that it has been found necessary to resort to ambulatory schools in them, the teacher gathering a group of pupils at a farm house and teaching them for a few weeks, and then passing on to another neighborhood to repeat the process. In 1850 there were 148,526 children receiving instruction in parochial schools, 126,178 in ambulatory schools, 6,228 in public schools, 17,465 in private schools, and 128,996 at home; total, 422,398. There are also in most of the towns gymnasia or collegiate schools for preparing students for the universities. There are normal schools for the training of teachers at Stockholm and Gothenburg, and two universities of high repute at Upsal and Lund. The former dates from 1477, and the latter from 1668; and the two have over 2,000 students.—The Lutheran church is the established church of Sweden, and but a limited toleration is granted to dissenters. The clergy are a powerful body, having an equal voice with the peasantry or the burghers in the national diet, and, with the nobles, to whom they are generally affiliated, possessing a controlling influence in the government. They are in the main a very moral and intelligent class, but extremely intolerant. They not only perform the duties of pastor and preacher, but are usually in the country parishes magistrates also. They have unlimited control over the national education of the country, which is under the immediate direction of each diocesan consistory. The head of the church is the archbishop of Upsal, and there are 11 bishops. The archbishop and bishops are nominated by the king from a list of candidates presented by the dioceses. From permanent funds, tithes, fees, &c., the clergy generally receive a very liberal income. No one but a member of the established church can hold office, and apostates from the national creed are liable to fine, imprisonment, confiscation of property, and banishment. If dissenters can obtain an authorization from the king, they may form societies, which will be recognized and tolerated. The periodical and newspaper press in Sweden exerts a powerful influence. There are several well conducted journals in Stockholm, and one or more newspapers in every considerable town of the kingdom. In 1850 the whole number of journals was 113.—The government of Sweden is a limited monarchy, hereditary only in the male line. The king is, in the language of the constitution and laws, the state, and is sole governor of the realm and commander of the land and sea forces. Upon his pleasure depend all military, civil, and ecclesiastical appointments. His action is exempt from all censure, but he is required to advise and consult with a council of state of 10 members, 2 ministers of state and 8 state

councillors, all of whom must be native Swedes. He is not bound to follow their advice, but if he proceeds to unconstitutional measures they must make a formal protest, or they are held responsible before a high court convened for their trial. The king may not interfere with the course of legal trial, nor can he pardon a convict without the consent of the latter. In practice, the king submits all measures except purely military and diplomatic affairs to his council. During the absence of the king in Norway, Sweden is governed by a regency named by him, and consisting of a prince of the blood or a minister of state and 3 councillors. In his absence from both kingdoms, or the minority of the sovereign, the two kingdoms are governed by a joint regency of 10 Swedes and 10 Norwegians. The law-making power is vested in the 4 estates of the realm, which are coeval with King Magnus Ericsson (1319). The house of nobles numbers about 900 members, of whom 800 usually assemble, the house of clergy about 54, and the house of burghers 60; and the house of peasants has 1 representative for every 21,000 constituents, making its number about 183. Each house has a separate and equal vote. Various attempts have been made to change their inequality of representation, but the nobles and clergy have always defeated them. The unrepresented class, nearly 900,000 in number, comprises those whose social positions are not in either of the 4 estates, and includes a large proportion of the scholars and men of science of the kingdom. The king has an absolute veto upon the acts of the diet or session of the "four houses," and may dissolve their sittings at his pleasure. The fundamental laws (viz.: the constitution of June 6, 1809; the arrangement of the diet of Feb. 10, 1810; the law of succession of Sept. 26, 1810; and the regulation of the liberty of the press of July 16, 1812) and the privileges of each order cannot be changed without the consent of all the orders of the states-general. In all other questions the votes of 3 of the orders decide. The sessions of the diet are triennial. The judiciary consists of the supreme court of the kingdom, composed of 16 judges in 2 divisions, which interprets the laws and renders justice in the name of the king, who may be present and is allowed 2 votes at its sittings; 3 royal courts of justice, at Stockholm, Jönköping, and Christianstad; a royal court of military justice; and a supreme court of admiralty. There are also petty courts throughout the kingdom, and the clergy are often magistrates of these. The estimate of receipts and expenditures of the Swedish administration for each of the 8 years ending Jan. 1, 1862-'3-'4, is as follows:

ANNUAL RECEIPTS.	
Ordinary.....	\$2,155,341
Extraordinary—Customs.....	\$2,941,500
Excises.....	106
Posts.....	871,000
Stamps.....	354,500
Brandy.....	1,855,000— 5,582,106
Total.....	\$7,677,447

ANNUAL EXPENDITURES.

Royal household.....	\$388,776
Justice.....	582,621
Foreign affairs.....	126,998
War.....	2,812,346
Marine.....	375,851
Interior.....	684,843
Finances.....	1,181,669
Public instruction and worship.....	868,248
Pensions, &c.....	309,764— 7,181,608
Annual excess of receipts.....	\$545,844

An extraordinary expenditure of \$2,385,967 per annum, for the construction of railroads, is provided for by special taxes, the excess of ordinary receipts, and other resources. The produce of government lands does not for the most part come into the budget, but is applied to the support of the army and certain of the civil functionaries. The army of Sweden is composed as follows: 1, enrolled troops (*varfvade*), who are recruited by volunteers usually enlisted for 6 years; 2, military colonists or troops in cantonments, who are exercised 4 weeks in a year, and have a house and lands furnished by government, and receive pay in money only when in active service; 3, militia of Gottland; 4, troops of the conscription. All Swedes of from 20 to 25 years are liable to military service. The entire force, exclusive of officers, is: enrolled troops, 7,692; militia of Gottland, 7,621; military colonists, 88,405; conscripts, 95,295; total, 144,013. The navy of Sweden consists of 10 vessels of the line, 6 frigates, 4 corvettes, 4 brigs, 9 steam corvettes, 20 war schooners, 77 gun boats, 122 gun launches, 6 mortar vessels, 23 small steam gun boats, 2 royal yachts, 21 transports, and 594 launches propelled by oars; in all 897 vessels. —The early history of Sweden is even more confused and mythical than that of Norway or Denmark. (See DENMARK, NORTHERN, NORWAY, and ODIN.) The realm founded by Odin and his Sviar or Swedes comprised probably only a portion of the central province or Svealand, and his capital Sigtuna was on or near the site of the present village of that name. The Odin dynasty ended with Olaf the Wood-Cutter, who was driven from power prior, it is supposed, to the 9th century, and his conqueror, Ivar, succeeded to the Swedish throne. After an uncertain period of tradition and fable, we find St. Anscarius visiting Sweden in 830, and preaching in the presence of King Biörn of the Hill to the pagan Swedes. Anscarius made some converts, but it was not till about the year 1000 that Olaf Skotkonung (the lap-king, so called from receiving homage while an infant) established Christianity as the national religion, and was himself baptized. Paganism was not fully expelled from his kingdom, however, for many years. Constant disputes and often open war followed for the next 3 centuries between the Goths and Swedes. In 1129 Inge II., king of Svealand or Swedeland, died, and the Swedes conferred the royal dignity on a private individual, Swerker I.; but as there was a claimant descended from a female branch of the royal family, named Eric,

who was supported by the Goths, the Swedes agreed that Eric should succeed Swerker, and that henceforth the representatives of each of the two families should reign alternately, assuming the title they still maintain of "king of the Swedes and Goths." Waldemar, son of Earl Birger (Birger Jarl), the founder of Stockholm, was elected king in 1250. In 1279 Magnus Ladulas (Barnlock, so called from his faithful guardianship of the people's granaries) ascended the throne, and reigned with extraordinary ability and justice till 1290, when he died while making preparations to start on a crusade. His death was succeeded by a long period of dissension between his 8 sons; in 1319 Magnus Smeck, then an infant, became king, and subsequently by right of his mother succeeded to the throne of Norway. He was deposed by the diet in 1348, and his son Eric elected his successor; but on Eric's death in 1359 he was restored. He established his son Haco in Norway, and induced him to marry Margaret, daughter of Waldemar, king of Denmark. The 3 Scandinavian states being thus allied, he attempted by the aid of the kings of Norway and Denmark to become absolute by abolishing the senate, but was deposed and Albert of Mecklenburg elected king. A war ensued between him and the kings of Denmark and Norway, which ended in Albert's defeat, and on July 20, 1397, by the "union of Calmar," Margaret, "the Semiramis of the North," became queen of Sweden, Norway, and Denmark. She retained possession of the triple government till her death in 1412, and was succeeded by her grand-nephew Eric of Pomerania. The union of Calmar was maintained with great difficulty for a little more than 100 years, though in 1436 it was seriously perilled by the efforts of the Swedes under the leadership of Engelbert, a patriotic Dalecarlian miner, and but for his assassination by the treachery of a Swedish noble in that year would have been overthrown. In 1442 Eric was deposed, and his nephew Christopher, duke of Bavaria, chosen king; and on his death in 1448 Canutson, who had been regent at the deposition of Eric, succeeded him. Denmark and Norway revolted, and when after a long war their revolt was quelled, Sweden rose against him. He died in 1470, and a condition of anarchy ensued till 1520, when the people, exasperated by the cruelty of Christian II. of Denmark, found a leader in Gustavus Ericsson, a noble of high rank, better known as Gustavus Vasa. (See GUSTAVUS I.) Christian had murdered, under circumstances of great atrocity, Sten Sture, at that time regent of Sweden, and had hanged as traitors 80 of the principal nobles, among them the father of Gustavus Vasa, and a great number of peasants. The resistance of the Swedes under Gustavus to the government of the Danish king was successful, and in 1523 they elected their leader king. At his death in 1560 he was succeeded by his son Eric XIV., who was deposed on account of alleged insanity in 1568 by his brother John. (See ERIC XIV.) John

reigned till his death in 1592, when his son Sigismund, who had been elected king of Poland and had become a Roman Catholic, succeeded him, the late king's brother, Duke Charles, being regent till he could leave his kingdom of Poland. Sigismund determined to establish Romanism in the kingdom, against the will of the people, and showed himself so cruel, reckless, and unscrupulous, that in 1604 he was deposed and his uncle Charles IX. was raised to the throne. His reign was one of tranquillity in the kingdom, and in 1611 he died, leaving the throne to his son, the celebrated Gustavus Adolphus. (See GUSTAVUS II.) After a reign of 21 years, the greater part of which was spent in constant war with Poland, Russia, and Germany, while his affairs at home were managed successfully by the wise Oxenstiern, he was slain at the battle of Lützen in 1632, and his daughter Christina, then 6 years of age, succeeded him. (See CHRISTINA.) Oxenstiern was invested with the chief management of affairs, and the kingdom for a time prospered, and by the peace of Westphalia in 1648 received considerable accessions of territory. After Christina's coming of age, her love of pleasure soon plunged the country into debt and trouble, and in 1654 she abdicated in favor of her cousin Charles X. His reign of 6 years was marked by brilliant battles and acts of great personal bravery, one of which, his crossing the Great Belt with his troops on the ice, is unrivalled in military daring, and enabled him to dictate terms of peace to the Danes at the gates of Copenhagen; but his victories brought no advantage to Sweden, and only wasted her resources. He died in 1660, and was succeeded by his young son Charles XI., during whose minority a peace was concluded by which the kingdom had 10 or 12 years of tranquillity. In 1676 commenced a war with the elector of Brandenburg and the Danes, which was continued with varying success, though for the most part with disaster, till 1679, when the peace of Fontainebleau, leaving the Danes at the mercy of the Swedes, enabled the latter to regain more than they had lost. An advantageous peace was concluded between the two kingdoms, and confirmed by the marriage of Charles to Ulrica, the daughter of the Danish king. During the remainder of his life he devoted his attention assiduously to the settlement of the troubles existing between the nobles and the peasants, and in 1698 prevailed upon both parties to give him the power to alter the constitution as he pleased. He died in 1697, bequeathing to his son Charles XII. this absolute power. (See CHARLES XII.) The warlike career of this remarkable but reckless king well nigh reduced his country to ruin. At his death in 1718, his sister Ulrica Elenora, wife of Frederic of Hesse-Cassel, after renouncing absolute authority and accepting a constitution from the nobles which restored their power, was elected by the diet to the succession. She soon resigned in favor of her husband, who recovered Pomerania from Denmark

in 1720, only by the payment of 600,000 crowns and the renunciation of all claim to exemption from the Sound dues. The next year he was forced to cede to the czar Livonia, Ingria, Esthonia, part of Karelia, Viborg, and the islands of Dago and Oesel. The king exerted himself to promote commerce and industry, and thus regain for Sweden some portion of its former consideration, which the reckless wars of its former kings had taken from it, but with only partial success. He died childless in 1751, and was succeeded by Adolphus Frederic, bishop of Lubeck, through the influence of the empress of Russia, who in consequence relinquished all the conquests she had made from Sweden except a small district in Finland. French influence corrupted the senate during his administration, and involved the country in a disastrous war with Prussia. After a turbulent reign of 20 years he died in 1771, and was succeeded by his son Gustavus. (See GUSTAVUS III.) The revolution of August, 1772, by which Gustavus attained absolute power, and the wars which followed with Russia and Denmark in 1787, and the act of safety of 1789, which abolished the senate, were the most marked events in the Swedish history of that time. He was assassinated in 1792, and his son Gustavus IV. (see GUSTAVUS IV.) ascended the throne; but being a minor, his uncle the duke of Sudermania was appointed regent. In 1809 his imprudence, and the tendency to insanity which he manifested, led to his compulsory abdication, and the duke of Sudermania was declared king under the title of Charles XIII. (See CHARLES XIII.) The peace made with Russia at this time deprived Sweden of Finland, one of her most valuable possessions. A new constitution, that still in force, was decreed, and the prince of Holstein-Augustenburg was elected heir to the throne as crown prince. The assassination of this prince in April, 1810, led very unexpectedly to the nomination of Bernadotte, prince of Ponte Corvo (see BERNADOTTE), as crown prince, whose success in securing Norway to Sweden endeared him to the people. In 1818, on the death of Charles XIII., he ascended the throne as Charles XIV. During his reign Sweden prospered, commerce, the arts, and manufactures made rapid progress, and the moral and social condition of the people was greatly advanced. His son Oscar I. succeeded him at his death in 1844, and encouraged the moral, social, and political progress of the country. He was esteemed one of the most accomplished monarchs of Europe. At his death in 1859, he was succeeded by his son, the present monarch, Charles XV., who had been regent of the kingdom since 1857 in consequence of King Oscar's illness. During the Crimean war Sweden and Norway remained neutral, but in a treaty with France and England bound themselves, in return for a guaranty of protection against encroachment, never to cede territory to any power without the consent of the contracting parties.

SWEDEN, LANGUAGE AND LITERATURE OF. The Swedish is one of the Scandinavian tongues, and as such belongs to the family of the Indo-European languages. Its immediate parent is the Icelandic or Old Northern, the primitive speech of the whole Scandinavian peninsula and of Denmark, and the language of the runic monuments which were erected throughout northern Europe between 900 and 1800. The grammatical forms and vocabulary of the parent tongue have been much better preserved in the Swedish than in the Danish, another daughter of the Old Northern. The line which separates the Swedish from the Icelandic is an arbitrary one, drawn through the middle of the 13th century. In its earlier stages the Swedish was influenced by the German through the commercial connection of Sweden with the Hanseatic towns, by the Latin through the Catholic priesthood and the monastic institutions, and by the Danish through the political union of Sweden and Denmark subsequent to the pact of Calmar (1397). The reformation again subjected it to Teutonic influences, but it was less affected by them than was the Danish. The language was greatly purified and a multitude of foreign vocables driven out by the efforts of the zealous Icelandic scholars of the latter half of the 17th and first quarter of the 18th century. But later in the last century the French tastes prevalent at the court and in the literature introduced a large number of Gallic words, many of which, however, have been since superseded by genuine Scandinavian derivatives. It has 28 letters, the same as in English, with the omission of *w* and the addition of *ä, å, ö*. Formerly the German character was mostly used in Swedish works, but now the Latin character prevails, though the former is still sometimes to be found. A letter peculiar to the Swedish is *ä*, which is pronounced almost like the English *o* in *note*. The vowels *a, e, i, ä*, and *ö* are pronounced as in German; *o* has 2 sounds, either similar to that of the English *o* in *more*, but intermediate between *o* and *u*, or equivalent to the English *a* in *fall*. The sound of *u* is intermediate between the German *u* and *ä*. *Y* is pronounced almost like the German *ä*. The pronunciation of the consonants is not so uniform as in German, but less variant than in English and French. *G* before *a, i, y, ä, ö*, has a sound like the English *y* in *you*. *K* before *a, i, y, ä, ö*, is soft and pronounced like *ch* in *much*. *Sk* before the same letters, and the combinations *skj, sj, stj*, are pronounced like the English *sh*. The indefinite article *en* (masc. and fem.) and *ett* (neut.) is placed before the noun; as *en häst*, a horse, *ett bord*, a table. The definite article is *den* in the masculine and feminine, *det* in the neuter, and *de* in the plural for all genders; as *den man*, the man; *det hus*, the house; *de män*, the men. The definite form of a noun is also expressed by only adding in the singular number *en* or *n* to masculine and feminine substantives, and *et* or *t* to the neuter; as *mannen*, the man,

bordet, the table; and in the plural, *na, na, a, en*; as *håstar*, horses, *håstarne*, the horses; or, thirdly, both these ways of expressing the definite form of the noun may be combined, as *den mannen, det bordet, de hästarne*. Substantives have a distinct case ending only in the genitive, which is formed by the addition of *s*. The plural of substantives is formed by adding *or, ar, er, or en*; and in some words the singular and plural are alike. The adjectives are formed after 2 declensions, the first of which has a separate form for the neuter gender, while the second has only one form for all the 3 genders. An awkward characteristic of the Swedish is the absence, in conversation, of any pronoun of address, the second person singular being used only among intimates or to inferiors, and the second person plural only in orations and sermons. In place of these the title of the person addressed, if he have one, with the third person, must be employed; otherwise the words *Herr* (sir, Mr.) to males, and *Fru* (madam) or *Mamsell* (miss) to females, must be used; thus: Have you seen the book? *Har Herrn* (Has the Mr.) *set boken?* *Har Fruen* (Has the madam) *set boken?* There are, as in the other Scandinavian and Germanic languages, a strong and a weak form of conjugation. The verb has only 2 simple tenses, present and imperfect; all the others are formed by means of auxiliaries. The passive is formed by adding *s* to the active, and has the same 2 simple tenses with the active; as, *att skära*, to cut; *att skäras*, to be cut; *jag kallar*, I call; *jag kallas*, I am called; *jag kallade*, I called; *jag kallades*, I was called. Throughout the verbs the singular is the same in all the 3 persons; in the plural the 1st and 3d are alike, and the 2d ends in *en*. The similarity between the Swedish and English is shown by the following stanzas from one of the cantos of Tegnér's *Frithiofs Saga*:

Då steg Frithiof upp och lade

Then stood Frithiof up, and laid

Hilding's hand i sin och sade:

Hilding's hand in his and said:

"*Fader, jag har svarat redan,*

"Father, I have answered already,

Du har hört min ejde beslut.

Thou hast heard my soul's resolve.

"*Råd, att Beles söner lära*

"Ride, that Beles's sons (may) learn

Head jag sagt; de kränkt min dra;

What I (have) said; they (have) stained my honor;

Jaga band eid dem mig följa;

Not a bond with them me fastens;

Aldrig blir jag deras man."

Never (will) be I their man."

"*Väl, din egen bana vandra,*

"Well, thy own career wander,

Ej kan jag din vrede kändra,

Not can I thy wrath condemn,

Odin styrer till det bästa,"

Odin steers for the best,"

Sade Hilding och försvann.

Said Hilding and vanished.

The dialects of the Swedish are as numerous as the provinces of the country. Those of Dale-

carlia and Gottland present the greatest departure from the written language, while that of Södermanland approaches it the nearest. The dialects of Scania and Blekinge possess the greatest similarity to the Danish, the southern portion of Sweden having remained under the rule of Denmark to a late period. In the northern provinces the approximation to the old Icelandic forms and vocabulary is much more marked than in the southern, where the peasantry have been exposed to Danish and German influences. The Swedish is the language of the educated classes, and in general of the press, in the Russian grand duchy of Finland. Among the best grammars of the language are the Swedish works of Fryxell, Rydqvist, and Strömborg, the German of Dietrich, and the English of May; among the best dictionaries, those of Ihre (Upsal, 1769) and Dalin (2 vols., Stockholm, 1850-'54).—LITERATURE. The literature of Sweden, until very recent times, presents fewer points of general interest than that of almost any other European nation. This is chiefly owing to the isolation of the country, for only during two brief periods in her annals—the reigns of Gustavus Adolphus and Charles XII.—has Sweden occupied a political position which brought her into influential contact with foreign lands; and of these brilliant eras only the former exercised any influence upon her literature. Her literary history has been very conveniently divided by native writers upon the subject into six periods.—I. 1250 to 1520. The earliest writings extant in the Swedish language are the ancient provincial laws, of which the oldest compilation, that of the province of Westergothia, was probably made about the middle of the 13th century. That they had existed for some time previous in an unwritten state seems to be indicated by the numerous alliterative or rhythmical phrases with which they are interspersed. The poetical spirit of the nation was first developed in the *Kämpvisor*, or heroic ballads, and a little later in the *Riddarvisor*, or chivalric ballads. Of these several collections have been edited; a few of them may perhaps be ascribed to the latter part of the 18th century, but the greater part of them belong to the 14th and 15th centuries. In style, and especially in the simple beauty of the melodies to which they were sung, they are excelled by the ballad literature of no other country. More artificial, but of greater influence upon the written language, were the rhymed romances of chivalry which found their way into the north from central and southern Europe, where they were so common during the middle ages. The oldest of these in Swedish were translated between 1800 and 1812 by order of Euphemia, queen of Norway, and were popularly called *Drottning Euphemias Visor*, "Queen Euphemia's Songs." They were *Hertig Frederik af Normandie, Ican och Gavian, Konung Artus, Karl Magnus, and Flores och Blansecflor*. Other versions and paraphrases and a very few original romances fol-

lowed them. Of little poetical but of considerable historical value are the two rhymed chronicles, *Den stora och den gamla Krönikarna*, "The Great and the Old Chronicles," narrating the leading events of Swedish history down to the reign of Christian the Cruel. Two bishops, N. Hermanni (died 1891) and Thomas (died 1443), are worthy of mention; the former, beside his translation of the life of St. Anscarius, wrote a "Legend of the Nun Elisif" in the ballad style; the latter composed some patriotic lyrics of a remarkable character. The abbey of Wadstena, founded by St. Brigitta (1302-72) in 1363, was the centre of much activity in religious literature during the century thereafter. A manuscript still in existence makes it probable that the foundress herself wrote her "Revelations" originally in Swedish, whence they were subsequently rendered into Latin by her confessor. Her daughter, the abbess Oatharine (died 1381), was the author of *Sjellinna Tröst*, "Soul's Trust," a paraphrase of a Latin ascetic treatise. The *Codex Vadstenensis*, a collection of legends from the German and Latin, several essays of a moral character, and some letters and diaries, were compiled or written by the monks and nuns of this foundation. An anonymous judicial treatise, *Domarereglerorna*, "Rules for Judges," written with much clearness and precision, and a curious political work, *Om Konunga- och Hufdinga-styrelsen*, "On the Government of Kings and Rulers," based upon the book of an obscure Latin author, Ægidius Romanus, are the only remaining noteworthy monuments of Swedish prose before the reformation. The libraries of Sweden during the Catholic period were unimportant, and were contained in the monasteries. By far the largest was at Wisby, in the island of Gotthland, which comprised 2,000 manuscripts. Printing was introduced into Stockholm in 1488, the first book printed being a collection of fables styled *Dialogus Creaturarum Moralizatus*. Presses were soon afterward established in Wadstena, Upsal, Westeras, Söderköping, and Malmö.—II. 1520 to 1600. The religious contests which followed the introduction of the reformed religion into Sweden continued during the whole of the 16th century, and gave a theological or rather polemical character to almost the entire literature. Two celebrated brothers, Olaus Petri (1497-1552) and Laurentius Petri (1499-1573), took a prominent part in the strife, and exerted an influence upon the literary development of their native tongue which can scarcely be overrated. Olaus was the author of the earliest translation of the New Testament (1526), of the earliest printed sermon (1528) and catechism (1530), and of the earliest dramatic composition in Swedish, *Tobia Comedia* (1550). He also wrote a *Svensk Krönika*, or chronicle of Swedish history, which was afterward rewritten by his brother Laurentius, the first Lutheran archbishop of the kingdom. The latter translated the Old Testament (1541), and compiled a code of ecclesiastical law; but the puri-

ty and strength of his style are seen to better effect in his sermons and in his psalm book, for which he composed 84 hymns, and which with some revisions was in use by the church for over a century. A liturgy known as *Rödboken*, the "Red Book," strongly Roman Catholic in its tendencies, was compiled by P. Fechten in 1576, and was a bone of contention for 25 years; it was defended by E. Nicolai (died 1580) and P. Paulinus, and bitterly attacked by M. Olai, N. Olai (died 1600), and other ultra Protestants. Beside the historical works of the brothers Petri, and some chronicles of the reign of Gustavus Vasa by R. Ludviksson (died 1594), P. Svart (died 1562), and S. Elofsson, there is little secular prose of value in the vernacular. The singular works of the last Catholic primate of Sweden, Johannes Magnus (1488-1544), *Gothorum Sveonumque Historia*, and of his brother Olaus (died 1568), *Historia de Gentibus Septentrionalibus*, were written and published at Rome in Latin. The poetry of the period is of little note. It consisted chiefly of hymns translated from the German, a few rhymed chronicles, and some popular ballads. J. Rondeltius wrote a dull religious drama, *Judas Redivivus*. Several hymns and a love song by King Eric XIV., and a *Visa*, or lay, by J. af Hoja (died 1585), exhibiting some power of imagination, are of greater poetic interest. The university of Upsal, nominally founded in 1476, was not permanently endowed until 1595, and did not begin to make its influence felt until the next century.—III. 1600 to 1718. The 80 years' war had a marked effect upon Swedish letters. Several libraries, captured in Germany, were sent to Sweden by Gustavus Adolphus; and the position which the military ability of that sovereign and the statesmanship of Oxenstierna gave to their country induced many learned foreigners to flock thither. Among them were Descartes, Salmasius, Vossius, Bochart, Huet, the younger Heinsius, Gronovius, Cassius, Pufendorf, Freinshemius, Loccenius, and Schefferus, most of whom were generously remunerated for their literary labors by the liberal patronage of Christina. Few of them, however, remained after her abdication. Their works were in Latin, as were those of many native writers. Of greater influence upon the vernacular literature were the researches into the antiquities of the North, and the study of the Icelandic literary monuments, which characterized the latter half of the 17th century and the earlier half of the 18th. Many Icelandic texts were published, including the Eddas, the writings of Snorro Sturluson, and a number of the historical and romantic sagas, accompanied with a prodigal display of erudition, which too often took the form of a puerile pedantry or wild speculation. The earliest, and in some respects the best of these zealous investigators was Olof Verelius (1618-82), who edited several sagas, giving the Swedish and Latin versions on the same page with the original, a style of publication generally adopted by his successors. He was followed by the

famous Olof Rudbeck (1680-1702), also celebrated as an anatomist and botanist, who, beside editions of Icelandic documents, wrote the *Atlantica*, a work full of misapplied learning, intended to prove that Sweden was the first home of the human race, and the Icelandic the original form of human speech. Its ingenuity and erudition aroused public attention upon its first appearance, but it is now chiefly famous as a bibliographical rarity, all but 4 of the copies of the 4th volume having been destroyed in a fire at Upsal. Johan Peringskjöld (1654-1720) published many of the ancient histories, including the bulky *Heimskringla* of Snorro Sturleson, and his Swedish translations were only inferior to those of Verelius in smoothness and perspicuity. Other scholars in this field were the brothers J. N. and P. Salanus, J. I. Reenhjelm (1644-'91), and the naturalized Icelanders J. Rugman and E. Olafsson. Johan Bureus (1668-1652), a man of comprehensive learning, J. Axehjelm, the laborious Johan Hadorph (1680-'92), and others published collections of runic inscriptions, and otherwise illustrated northern archaeology and linguistics. The foreigners Pufendorf, Loccenius, Boeclerus, and Schefferus wrote on the history of Sweden in Latin. The voluminous work of J. Mesenius (1579-1638), *Scandia Illustrata*, was given to the world by Peringskjöld 50 years after the author's death, and is of value as a thesaurus of materials. Eric Tegel (died 1688) wrote *Gustaf den Förstes Historia*, "History of Gustavus I.," as well as an account of the reign of Eric XIV.; histories of the times of the three first monarchs of the house of Vasa were also compiled by A. Girs (died 1689). The style of both is heavy. Equally as far from pleasing are the writings of J. Widekindi (1620-'97) on the Russian war of 1607-'17, and on the life of Gustavus Adolphus; but more commendable are those of J. Werwing (died 1697), who illustrated the reigns of Sigismund and Charles IX. Gustaf Adlerfeldt (1671-1709) narrated in French the military history of Charles XII. to 1709. The religious controversies of the previous period were continued through this, but assumed the shape of a contest between Lutheranism and Calvinism, or of doctrinal disputes. The principal theological writers were the bishops. Prominent among them were the archbishops L. Paulinus (died 1646), O. Svebilus (died 1700), E. Benzelius (1642-1709), and Haquin Spegel (1645-1714), and the bishops J. Terserus (1605-'78), J. Matthiæ, J. Rudbeckius (1581-1646), O. Laurilius, P. Winstrup (died 1679), E. Svenonius, and J. Baazius (1581-1649), all of whom distinguished themselves either in controversial theology, exegetics, or ecclesiastical history; but the greater part of them wrote in Latin. J. Gezelius (1615-'90), bishop of Abo, known as a Greek scholar, was still more famous for his commentary on the Bible. Jesper Swedberg (1668-1735), bishop of Skara, father of the celebrated Swedenborg, was a man of great

activity and influence; he wrote a *Postilla* or collection of sermons, several hymns of considerable poetic beauty, an account of the Swedish congregations in America under the title of *America Illuminata*, and many minor treatises. The field of metaphysics was principally occupied with discussions between the disciples of the scholastic philosophy and the Ramists, though a few of the Swedish learned professed themselves Neo-Platonists. There was little originality. Descartes had some followers, who greatly promoted the freedom of scientific investigation. In jurisprudence, beside Pufendorf and the prolific Loccenius, the names of M. Vexionius, author of *Politica*, a bold treatise on the rights of sovereigns, and of J. Stjernhök (1596-1675), who wrote a valuable treatise *De Jure Sueonum et Gothorum*, are well known. Some works of geographical interest appeared, such as the costly volumes of Count E. Dahlberg (1625-1703), *Svecia Antiqua et Hodierna*, comprising 353 maps and engravings of Swedish towns and castles, works on Lapland by Schefferus and J. Tornæus, the *Nya Sverige* or "New Sweden" of J. Campanius, the travels of O. Ralamb to Constantinople (1658), and those of N. Kjöping and Willmans to the East Indies (1666). Classical philology was much cultivated both by resident foreigners and natives, including among others Schefferus, Loccenius, Freinshemius, Gezelius, P. Lagerlöf, and J. Columbus. J. Bureus published the first Swedish grammar (1686), and Archbishop Spegel's *Glossarium Sævo-Gothicum* (1712) was the earliest Swedish lexicon. In other sciences, O. Rudbeck as a botanist paved the way for the great name which was to adorn the next period; U. Hjärne (1641-1724) and E. Odelstjerna treated of mineralogy; and J. Bilberg, M. Celsius, and A. Spole gained celebrity as astronomers and mathematicians. The only noteworthy works on literary history are the *Svecia Litterata* of Schefferus and the *Holmia Litterata* (1701) of R. von der Haardt. In poetry Georg Stjernhjelm (1598-1672) held the foremost place, and did much toward introducing a better taste. His most complete poetical work is *Hercules*, a sort of didactic epic in hexameters, exhibiting large imaginative power and much poetic skill. Of his masques the best is *Den fängne Cupido*, "The Captive Cupid." Stjernhjelm was the first writer of sonnets in Swedish. The drama consisted generally of dull imitations of Olaus Petri and Rondelitus, the chief writers being the historian Messenius, who attempted to exhibit the whole of Swedish history in a series of dramas, S. P. Brask (1618-'68), and A. J. Prytz (1590-1655). More classically dramatic in form, but scarcely better in style, are the *Rebecca* of J. Beronius and the *Rosimunda* of U. Hjärne, while but little more praise can be bestowed upon the dramatic allegories of J. P. Ohronander. The lyric writers may be divided into two schools, the Italian and the German. To the former belonged G. Dahlstjerna (1658-

1709), author of the *Kungaskald*, a half heroic, half elegiac poem in *ottave rime* on Charles XI., and of an unsuccessful translation of Guarini's *Pastor Fido*; and G. Rosenhane (1619-'84), whose longest metrical attempt, *Venerid*, is a collection of 100 sonnets. The chief representatives of the German school were S. Oulumbus (1642-'79), whose lyrics and pastorals are now nearly forgotten; L. Johansson (died 1674), whose *Helicon Blomster*, "Flowers from Helicon," published under the pseudonyme of Lucidor, is a collection of epithalamiums, elegies, and erotic songs, which are less remarkable than his hymns, and P. Lagerlöf (1648-'99), author of a *Visa* or love song of great popularity in its day. The many-sided Spegel, some of whose hymns are worthy of mention, wrote two heavy and monotonous poems, borrowing his titles from the two epics of Milton. O. Arosell is known as the author of a volume of *Ofverskrifter*, or epigrams, a few of which are of merit.—IV. 1718 to 1772. These years embrace a time of great political and of considerable literary activity. The natural sciences, under the influence of the world-famous Linné or Linnæus (see LINNÆ), occupy the first place. That great naturalist was surrounded by a crowd of pupils, a large number of whom became celebrated. Many of them undertook distant journeys, in order to extend their acquaintance with the productions of nature, and acquired reputation both as travellers and botanists. J. P. Falck (died 1773) explored Russia; P. Forskall (1736-'68) undertook a scientific journey to Egypt and Arabia, where he died, leaving the results of his researches to be published by his companion Niebuhr; F. Hasselquist (1722-'52) visited Asia Minor; P. Lofling (died 1756) went to Spain and thence to South America; P. Osbeck (died 1805) traversed the East Indies and China; D. Solander (1736-'81) accompanied Capt. Cook around the world (1768-'71); P. Kalm (1715-'79) journeyed through North America, and E. Laxman through Siberia. Others of equal zeal and industry, such as O. Bjerkander and J. G. Wahlbom, illustrated the flora of northern Europe. Linnæus, who devoted much labor to zoological classification, was excelled in this department by his friend P. Artedi (1705-'85), whose treatise on ichthyology he edited in 1738. To physiology belong the *Economia Regni Animalis* and *Regnum Animale* of Swedenborg. The entomological works of C. F. de Geer (1720-'78), published in French, are still esteemed. Eminent in chemistry were Torbern Olof Bergman (1735-'84), who correctly explained the composition of many salts previously misunderstood, and laid the foundation for the science of crystallography; A. F. Cronstedt (1722-'65), the discoverer of nickel; and J. G. Wallerius (1709-'85). Much attention was paid to mining by M. von Bromell (1679-1731), Swedenborg, and others. Olof Rudbeck the younger (1670-1740) distinguished himself in several sciences, one of his works being an

ornithology in 8 volumes. N. Rosén von Rosenstein (1709-'78) was the reformer of medical science in Sweden. Astronomy was illustrated by such names as A. Celsius (1701-'44), S. Klingensjärna (1689-1785), and P. W. Wargentin (1717-'83), all of European celebrity; mechanics by C. Polhem (1661-1751) and Swedenborg; and other branches of mathematics by J. Faggot, C. Falkengren, E. O. Runeberg, and others. Jurisprudence was represented by D. Nehrman (died 1769) and O. Rabenius (1730-'72). In theology, orthodoxy found new foes to combat in the pietists, the believers in Swedenborg, and the followers of Zinzendorf; but the bishops were in general men of less ability than in the preceding century. S. Alnander, J. Benzelius, P. Munch, L. P. Halenius (compiler of an excellent concordance to the Bible), P. Muhrbeck (who together with A. C. Rutström and E. Tollstadius underwent much persecution from the state church on charges of heterodoxy), and J. Serenius were the chief writers in the various departments of theology; but the science produced no very eminent man except Swedenborg. (See SWEDENBORG.) The best known metaphysician and thinker was the Cartesian A. Rydelius (1671-1738), author of *Förnuftsöfningar* ("Exercises in Reason"), and other philosophical essays; the system of Wolf was supported by P. Högström, N. Wallerius, and O. Mesterton; that of Locke by A. Schönberg (1737-1811) in his *Inledning till den naturliga Lagen och Sedoläran* ("Introduction to the Laws of Nature and Morals"), by F. Kryger (1707-'77) in his *Naturlig Theologi*, and by E. O. Runeberg. A laborer of importance in the province of philology was Johan Ihre (1707-'80), whose *Glossarium Sæco-Gothicum* was a great improvement on the dictionary of his predecessor Spegel, and whose Swedish dialect lexicon and researches concerning Ulfilas and the Mæso-Gothic give evidence of great learning and diligence. The Icelandic scholars of the preceding generation were followed in the earlier portion of this period by J. F. Peringskjöld (1688-1725), E. J. Björner, Count G. Bonde (1682-1764), J. Göransson (editor of the elder Edda and compiler of *Bautil*, a collection of 1,000 runic inscriptions), and N. R. Brocman, all of whom gave to the world editions of old northern writings, but whose commentaries were lessened in value by the same hyperbolical extravagance which characterized those of their predecessors. Before the middle of the 17th century the taste for Icelandic studies greatly declined. The description of Sweden by E. Tuneld is the only special geographical work of note, and in addition to the travels already enumerated only those of J. J. Björnstaahl (1781-'79) through Europe deserve mention; they abound in classical learning and literary information, and have been translated into several languages. In history, as in polite literature, Olof Dalin (1703-'68) stands at the head of this period. His journal *Den Svenska Argus*, "The Swedish Argus"

(1782-'4), an imitation of the English "Spectator," exerted a weighty influence upon the prose style of the language and the literary taste of the nation. His *Svea Rikes Historia*, "History of the Swedish Realm," ends with the reign of Charles IX., and, though wanting in critical ability, is eloquent and pleasing. A more rigorous examination of evidence characterizes the Swedish histories of A. af Botin (1724-'90) and P. Schönström. The history of Charles XII. by G. Norberg (1677-1744) is valuable as an account by an eye-witness of most of that monarch's military adventures; and the "Memoirs of Christina" by J. Arckenholtz, written in French, has been of great assistance to succeeding writers. O. Celsius the younger (1716-'94) wrote histories of the reigns of Gustavus Vasa and Eric XIV., and rendered a great service to Swedish letters by establishing the *Tidningar om de Lärdes Arbeten*, "Journal of the Works of the Learned," the first critical periodical in the language. In this work he was followed by C. O. Gjörwell (1781-1811), a very prolific writer, who conducted with marked ability *Den Svenska Mercurius* and other literary and historical serials. Of the 7 volumes of the *Bibliotheca Sæo-Gothica* of A. A. von Stjernman, only the first has been published; but the voluminous and wonderfully accurate *Bibliotheca Historica Sæo-Gothica* of O. G. Warmholtz (1710-'84) dates from this period, although not given to the public until 1782-'92. Stjernman, E. Benzelius (1675-1745; a man of various and extended erudition), B. Bergius (1728-'84), G. Wallin (1686-1760), and S. Loenbom (died 1776) were laborious critics, editors, and collectors, and brought to light or illustrated a great number of early Swedish monuments. Dalin's poetical works comprise a dry allegorical epic, *Den Svenska Friheten* ("Swedish Freedom"), a cold and languid tragedy, *Brynhilda*, a lively comedy, *Den afundsjuke är qvick* ("The Jealous Man is Sharp-witted"), an ingenious and forcible satire, *April-verk*, and many minor pieces which are generally pleasing without much depth or vigor. H. O. Nordenflycht (1718-'63), a woman of singular ability, left a high name as a writer of lyrics, and was the centre of a literary circle which after her death became widely known as the society *Utile Dulci*. Among her lettered friends were two noblemen, Count G. P. Creutz (1729-'85), author of a tolerably felicitous pastoral, *Atis och Camilla*, and Count G. F. Gyllenborg (1781-1808), who composed lyrics, elegies, satires, and fables, in a smooth and correct, but too often prosaic style. Lyricists of less note were A. Odel (died 1773), U. Rudenschöld (1698-1788), O. Bergklint (1733-1806), and O. Kolmodin (1690-1753). The writers of France served as models to numerous Swedish authors during this period from Dalin downward, and all the tragedies of the time, by E. Wrangel, H. Hesselius, O. Celsius the younger, and others, were lifeless imitations of Gallic prototypes. Such was the case

too with the tedious romances of J. H. Mörk (1714-'68), the first Swedish novelist. Molière, Voltaire, Boileau, La Fontaine, Marmontal, and Fénelon were translated and sedulously imitated. Two important learned associations were founded in the first half of the 18th century, the Upsal society of science (1728) and the royal academy of science at Stockholm (1739); the transactions of both are of great scientific value. *Vitterhets Akademien*, the "Academy of Belles-Lettres," established by Queen Louisa Ulrica in 1753, was suspended in 1756, but was revived in 1782 as the academy of belles-lettres, history, and antiquities, and publishes chiefly historical and archaeological matter.—V. 1772 to 1809. The earlier portion of this period took its impress to a great extent from the character of the sovereign, Gustavus III. His influence was not beneficial to the higher walks of literature, but he founded the "Swedish Academy of Eighteen" (1786), and otherwise sought to encourage letters. The pupils of Linnaeus continued to be the chief scientific men of the time, and labored earnestly for the advancement of science. C. P. Thunberg (died 1798), author of the *Flora Japonica*, travelled in the extreme East; A. Afzelius visited Sierra Leone; and A. Sparman went to South Africa, and subsequently accompanied Forster and Cook to the South sea (1772-'6). Of other naturalists, E. Acharius (1757-1819) acquired a universal celebrity for his studies in lichenography, O. Swartz (1760-1817) illustrated the flora of the West Indies, A. J. Retzius (1747-1821) was a fertile writer on botany and zoology, and O. Qvensel began in 1802 the publication of an important work, *Scensk Botanik*, a general treatise on the Swedish flora. As chemists and mineralogists, the period furnished C. V. Scheele (1742-'86), regarded as one of the founders of organic chemistry, J. G. Gahn (died 1818), to whom several chemical inventions are due, J. J. Ankarström, and S. Rinman. D. Manderhjelm (died 1810), F. Mallet (died 1791), and H. Nicander were widely known for their astronomical labors. Juridical writers were M. Calonius (died 1817), L. Tengvall, and others. Medical science was cultivated by O. af Acrel (died 1807), who enjoyed a deserved celebrity as a surgical author, and D. Schulz von Schulzenheim (1782-1823). There was little literary activity in the theology of the age, but the labors of A. Knös in dogmatics and of S. Ödman (1750-1829) in exegetics were of high reputation in their day. More æsthetical than metaphysical was Thomas Thorild (1759-1808); his last and most philosophical work, *Archimetria*, is in Latin. Another name of note in æsthetics is C. A. Ehrensvärd (1745-1800), author of an excellent and acute treatise on the fine arts, *De fria Konsternas Filosofi*. Somewhat later than these was the philosopher B. O. H. Höijer (1767-1812), who has explained in a clear, distinct, and graphic style his own system, which is based upon those of Fichte and Schelling. A geographer of great industry was

D. Djurberg, but he possessed little scientific ability. The travels of O. B. Wadström (1746-'99) to the W. coast of Africa, of U. von Troil to Iceland, and of O. Agrell to Morocco, have been translated into various languages. Sven Lagerbring (1707-'87) is to be regarded rather as a collector of historical materials than as a historian, although his *Seea Rikes Historia*, too often inaccurate, was looked upon as a national work by his contemporaries, and its author was richly rewarded by the Swedish estates. His other writings are numerous. E. M. Fant (1754-1817) compiled a *Diplomatarium* and an extremely valuable collection of *Scriptores Rerum Suecicarum*. Comprehensiveness and exactness were the distinguishing traits of Jonas Hallenberg (1748-1834), author of a universal history from the beginning of the 16th century, and of many other works, historical, archaeological, or philological. H. G. Porthan (1739-1804) investigated the history and antiquities of Finland. Special periods or departments of Swedish history were illustrated by O. G. Nordin (1749-1812), O. Knös (died 1804), J. A. Rehbinder, S. L. Gahm, and U. von Troil (1746-1808). G. Gezelius (1732-'89) compiled the first noteworthy biographical lexicon of distinguished Swedes. Under the direct influence of the monarch, the French taste, which had so largely developed itself in the preceding period, now became almost entirely prevalent. Gustavus himself wrote some dramatic pieces of much merit, but all frigidly French. He was a speaker of considerable force and grace, and oratory became a much studied art. The rhetorical and verbose eloquence of the day was best represented by N. von Rosenstein (1752-1824) in the rostrum, and M. Lehnberg (1758-1808) in the pulpit. The favorite poets at the court of Gustavus III. were Kellgren, Leopold, and Oxenstiern. J. H. Kellgren (1751-'95) was famous in his time in almost every branch of the poetic art, and exercised much influence upon public taste as editor of *Stockholms Posten*, "The Stockholm Post;" his best productions are a satire, *Ljusets Fiender*, "The Foes of Light," and his lyrical dramas and minor pieces. O. G. af Leopold (1756-1829), who has been styled not very appropriately "the Voltaire of Sweden," wrote some didactic poems in the style of Pope, many serious lyrical pieces, some humorous poems which are still pleasing, and two tragedies, *Odin* and *Virginia*. Count J. G. Oxenstiern (1750-1818) was the translator of Milton, and author among other things of two agreeable descriptive poems, *Dagens Stunder*, "The Hours of the Day," and *Skördarna*, "The Harvest." The lyrics of M. Chorusæus (1774-1806), the *Spåstara* and *Medea* of B. Ligner (1759-'98), the poet of the passions, and the translations from Virgil, Horace, and Ovid by O. E. Adlerbeth (1751-1818), are yet read with pleasure. A few poets escaped the general contagion. Foremost among these was Karl Michael Bellman (1740-'95), a song writer of the highest pow-

ers and most glowing fancy. His songs are all set to appropriate melodies by himself, the two chief collections being known as *Fredmans Epistlar* and *Fredmans Sångar*, the epistles and songs of Fredman. Two of his friends, C. I. Hallman (1782-1800) and O. Kexél (1748-'96), were comic dramatic writers of worth, the best production of the former being an afterpiece, *Tillfället gör Tyfven*, "Opportunity makes the Thief," and of the latter a comedy, *Kaptén Puff*. The verse of a female writer, A. M. Lenngren (1754-1817), much of it humorous, possesses a grace and smoothness unusual among her contemporaries. A curious book of travels entitled *Min Son på Galejan*, "My Son in the Galley," by J. Wallenberg (1748-'78), is partly in verse, and abounds in a coarse but lively wit. The last years of this period, comprising the reign of Gustavus IV., exhibited little literary life. Freedom of the press, which had been established in 1774, and had been somewhat restricted in 1780, was altogether abolished in 1798, and a systematic censorship enforced. The Swedish academy was suspended for some months in 1795, Thorild was banished, Leopold was ordered away from the capital, and Höijer was not allowed to write.—VI. 1809 to 1861. With the political revolution of 1809, the literature of Sweden was endowed with a new spirit; poetry abandoned its tawdry Gallicism, and prose was greatly developed by a general substitution of the vernacular for the Latin in the works of the learned. Schools have largely improved both in number and character, and libraries have increased. The scientific world has again been taught to look to the North for one of its great lights, and has recognized in Johan Jakob Berzelius (1779-1848) a luminary scarcely less lustrous than Linnaeus. His great services in every department of chemistry have been universally acknowledged. His principal works are *Föreläsningen i Djurkemi* ("Lectures on Animal Chemistry"), *Lärobok i Kemi* ("Text Book of Chemistry"), the latest and best editions of which are in German, and a long series of annual reports on chemistry and physics published by the Swedish academy of sciences. His chief pupil was N. G. Sefström (died 1845), esteemed both as a chemist and geologist; but better known as geologists are Hisinger, author of the *Lethæa Suecica* (1837-'40), and Angelin, author of a still later treatise, *Palæontologia Suecica*. As botanists the reputation of three men has extended beyond their native land: Elias Fries (born 1794), whose *Systema Mycologicum* (1821) made an epoch in the study of the fungi; K. A. Agardh (born 1785), author of the *Systema Algarum* and of important treatises on the physiology of plants; and G. Wahlenberg (1780-1851), who continued the *Svensk Botanik* of Qvensel, and contributed to a knowledge of the Scandinavian flora. Other eminent names in this science are P. F. Wahlberg; O. J. Hartman (died 1854), author of a *Svensk Flora*; J. E. Wikström (died 1856), compiler of a botanical bibliography; J. G.

Agardh, who has continued his father's researches into the algæ; and J. E. Areschoug. Zoology has a famous cultivator in Sven Nilsson, author of *Skandinavien Fauna*, and of a remarkable treatise, *Skandinaviska Nordens Urinseodmars* ("The Scandinavian North's Primeval Inhabitants"), an ethnographical work which has materially changed the opinions of the learned concerning the primitive history of northern Europe. Entomology has been ably treated by J. W. Dalman (died 1828); O. J. Schönherr, in his *Genera et Species Curculionidum* (1833-'45), containing the results of 30 years' labor; and S. W. Zetterstedt, in his extensive *Diptera Scandinavia*. The chief laborer in ornithology, beside Nilsson, has been O. J. Sundevall. Among mathematicians J. Svanberg, and among physicists Z. Nordmark (died 1828), F. Rudberg, and F. W. von Ehrenheim (died 1828), have gained considerable eminence. Medical science furnishes the names of A. A. Retzius (died 1860), whose discoveries in anatomy conferred upon him a European fame, and J. Hvässer, a writer on the theory of medicine. The ancient provincial codes have found an able editor in O. J. Schlyter, while committees of eminent lawyers have elaborated new codes for the whole kingdom. Prominent legal scholars have been L. G. Rabenius, E. Bergfalk (also known as a political economist), J. J. Nordström, F. Schrevelius, O. Nauman, J. O. Lindblad, and J. G. Carlén. In the domain of politics a large literature has sprung up during the present century. A few names are J. A. Hartmansdorff, M. F. F. Björnstjerna (born 1799), E. S. Bring, P. G. Oedersjöld (died 1860); J. P. Theorell (born 1791), who edited from 1823 to 1832 the *Dagligt Allehanda*, an influential journal; his brother S. L. Theorell (born 1784), of still greater ability and fertility; A. Lindeberg, editor from 1821 to 1833 of *Stockholms Posten*; M. J. Oruzenstolpe (born 1795), author of *Ställningar och Förhållanden* ("Situations and Relations") and other politico-historical works, in an excellent style, but characterized by a bitter controversial spirit; L. J. Hjerta (born 1801), from 1830 to 1851 conductor of the *Aftonblad*, a liberal daily journal which still stands at the head of Swedish journalism; and P. E. Svedbom (died 1856), a forcible writer, who succeeded Hjerta as editor of the *Aftonblad*. The metaphysicians have chiefly copied Fichte, Schelling, or Hegel, and have produced little that is new. The Fichte-Schelling school is represented by the historian Geijer, the poet Atterbom, S. Grubbe (born 1786), and N. F. Biberg (1776-1827); while Hegel's theories have found defenders in E. S. Bring and J. W. Snellman. Later metaphysicians are O. J. Boström and S. Ribbing. Purely æsthetic are Atterbom and Hammar-sköld, in numerous treatises and articles, and A. Törneros (1794-1838), who wrote in a style resembling that of Richter. Swedish geography and statistics are much indebted to W. Tham and C. af Forsell, the former having for

some years been engaged upon a minute description of Sweden, and the latter having published *Statistik öfver Sverige*, "Statistics of Sweden." F. W. Palmblad wrote (1823) a noteworthy work on Palestine and an incomplete geographical handbook on a large scale, while G. Thomée and Rietz have both given to the public works of merit on this science. Travellers have been rather numerous than important. P. Læstadius has described Lapland (1828-'33); J. Berggren has visited the Holy Land (1826-'8); Turkey and Persia were explored by G. von Heidenstam (1828), Egypt by Hedenborg (1841), the East Indies and China by G. von Düben (1844-'7), and North America by A. Klinkowström (1818-'20), C. D. Arfwedsson (1822-'6), F. Bremer (1854), and C. A. Gosselman (1828-'39). An account of a circumnavigation of the globe was published by N. J. Andersson (1851-'3). The grammar of the Swedish language has been best treated by J. E. Rydqvist (born 1800), while the Swedish dictionary of A. F. Dalin, finished in 1855, has supplied a long felt want. The mother tongue (the Icelandic) and its literature, after remaining unstudied for more than half a century, have again received much attention. A. A. Afzelius (born 1785) translated the elder Edda and other texts, while versions have been published by Kröningsvård, A. J. D. Onattingius (born 1792), Carl Sæve, a profound philologist, and others. A. O. Lindfors issued (1829) an *Inledning till Isländska Litteraturen*, "Introduction to Icelandic Literature." The Mæso-Gothic is largely indebted to A. Upström, who has published a critical edition of *Ulfilas*. In other philological departments only M. Norberg (died 1826), C. M. Agrell (died 1840), and O. F. Tullberg in Syriac, and J. Berggren (born 1790), compiler of a French-Arabic lexicon, are known abroad. Since the change of government the established church, opposed as it always has been to progress, has had many foes to contend against, including the rationalists, the followers of Strauss, the Baptists, the Separatists, and especially the so called *Läsare* or Readers, a sect not unlike the Methodists in doctrine and practice. The chief names in doctrinal theology are H. Reuterdaahl, now archbishop, a disciple of Schleiermacher, M. E. Ahlman, G. Knös (died 1837), L. G. Anjou, F. G. Hedberg, a Finnish priest, A. Wiberg, the defender of baptism, and N. Ignell. In exegetics the prominent writers are B. J. Bergqvist, author of *Förnuft och Uppenbarelse* ("Reason and Revelation"), J. H. Thomander (born 1798), editor with Reuterdaahl of the *Theologisk Quarterly*, and Bishop Agardh; in pastoral theology the most noted are A. G. Knös and A. Z. Pettersson. As preachers, H. Schar-tan, Archbishop Wallin, O. G. Rogberg, C. P. Hagberg, and others have gained a high reputation for eloquence, and have all published collections of sermons. Archbishop Reuterdaahl is the author of a fine piece of historical criticism, *Senaka Kyrkans Historia* ("History

of the Swedish Church"), which only reaches to 1889; L. G. Anjou has published an excellent *Scenska Reformationens Historia* ("History of the Swedish Reformation"), which has been translated into English; and J. J. Thomens (died 1845) has written the only complete history of the Swedish church. The teachings of Swedenborg have been zealously followed by J. Tybeck, O. U. Beurling, and A. Kahl. Swedish history has never before been so devotedly studied. Excelling all in grace and dignity of style and in philosophical treatment, if not in the critical examination of materials, the first place is due to Eric Gustaf Geijer, (1783-1847), whose *Sees Rikes Häfder* ("Annals of the Swedish Realm") and *Scenska Folkets Historia*, the former a fragment and the latter ending with the abdication of Christina, are models of historic composition. Less successful has been the *Scenska Folkets Historia* of A. M. Strinnholm (born 1787), reaching down to 1819. More complete is the work of Anders Fryxell (born 1795), who, under the modest title of *Berättelser ur Scenska Historien* ("Narratives from Swedish History"), has published a national history, in a perspicuous and not inelegant style, which extends through the reign of Charles XII. and is still continued. Special historical writers are P. A. Granberg, in his *Kalmars Unionens Historia* ("History of the Calmar Union"), *Folkungättens Historia*, and other works; G. A. Silfverstolpe (1772-1824), in his *Scenska Statsförfattningens Historia* ("History of the Swedish Constitution"); J. F. af Lundblad (born 1791), in his histories of the times of Charles X. and Charles XII.; A. Cronholm in his *Värngarna* ("The Varangians") and *Vikingatågen* ("Expeditions of the Vikings"); A. A. Afzelius in his *Scenska Folkets Sagohäfder*, an agreeable and interesting work on the popular superstitions, religious belief, traditions, and customs of the Swedish peasants; H. Järta, A. I. Arwidsson, and many others. Historical collections are the *Handlingar rörande Skandinaviens Historia* ("Transactions relating to the History of Scandinavia"), published in annual volumes since 1816; the *De la Gardie'ska Arkivet*, or "Archives of the De la Gardie Family," edited by Wieselgren; and the collections issued by the brothers O. and G. Adlersparre, A. Wallmark, Kröningsvärd, G. Bonde, O. F. Rothlieb, O. G. Malmström, and several others. The foremost archaeologists of the period are N. Sjöberg, author of *Samlingar för Nordens Fornälskare* ("Collections for Lovers of the Old North"); J. G. Liljegren (died 1837), who began a *Diplomatarium Suecanum*, and wrote two standard works on runes, *Runlära* and *Runurkunder*; A. E. Holmberg, known by his excellent *Skandinavien Hällristningar* ("The Pictured Rocks of Scandinavia"), and his popular *Nordben i Heledomen* ("The Northmen in Heathen Times," 1853); B. E. Hildebrand, a learned numismatist; O. G. Brunius, and R. Dybeck. O. E. Ehlén-Cavallius, H. Klemming, J. A. Ahl-

strand, and others founded the *Fornskrift-Sällskap*, which has edited a large number of Swedish mediæval writings. *Scenska Vittnehetens Historia* ("History of Polite Letters in Sweden"), by L. Hammaraköld (1785-1827), an author of much research, but of erroneous views in criticism, was the first important work of its kind. It has been followed by the more extended treatise of P. Wieselgren (born 1800), *Sveriges sköna Litteratur*, which has some faults, but is on the whole of great value; by the excellent *Scenska Siare och Skaldar* ("Swedish Seers and Bards") of Atterbom; by the *Framfarna Dagars vittna Idrotter* ("Learned Labors of Past Times") of J. E. Rydqvist; and the able manuals on Swedish literary history of O. J. Lénström. The *Biographiskt Lexikon*, a biographical dictionary of celebrated Swedes, edited by Palmblad and subsequently by Wieselgren, is a colossal work of great worth and research in 25 volumes. This is the brightest age in the annals of Swedish poetry. In some of the earlier verse writers of the period traces of the Gustavian school are visible; but these soon gave way to a better spirit. F. M. Franzén (1772-1847) has gained a lasting renown by his naïve and idyllic lyrics, and by his beautiful elegy on Orentz; less read are his *Gustaf Adolf i Tyskland* ("Gustavus Adolphus in Germany"), his fragmentary epic *Columbus*, and his didactic and dramatic pieces. J. O. Wallin (1779-1889), celebrated as an eloquent preacher and orator, began his poetic career with some heavy prize poems in Alexandrines and some dry didactic essays; but his style subsequently changed, and some of his shorter pieces are of great beauty. He revised in 1819 the Swedish psalm book, a collection of religious verse hardly excelled in modern hymnology, which had been previously edited by Spiegel (1696), and others. Wallin added 117 psalms by himself and 78 by Franzén, inferior to none in the book. J. D. Valerius, best known by his bacchanalian songs, and J. M. Silfverstolpe (1777-1881), rather a translator than an original poet, both belonged to the earlier part of the century. Two new poetic schools, of vast influence upon polite literature, arose at the beginning of this period, the romantic and the Gothic. The former was represented by the journals *Polyfem* (1810-'12), edited by J. O. Askelöf (born 1787), and *Fosforos*, whence its members are sometimes styled *Fosforister* or phosphorists. At the head of this school stood P. D. A. Atterbom (1790-1855) as a poet, and Palmblad and Hammaraköld as critics. Atterbom's long poem, *Lycksalighetens Ö* ("The Island of Bliss"), his *Blommorna* ("The Flowers"), and many of his shorter lyrics, are characterized by depth of fancy and feeling. Other *Fosforister* were O. F. Dahlgren (1791-1844), author of *Mollbergs Epistlar*, an imitation of the songs of Bellman; O. E. Fahlcrantz (born 1790), a successful humorist in his *Noaks Ark*, but less happy in his religious epic, *Anagarius*; and J. O. Nyberg (born 1785), a fe-

male writer of considerable ease and grace, better known as Euphrosyne. The Gothic school, which has left a more permanent impress upon poetry, developed its theories through a society, the *Göthiska Förbundet* (the "Gothic Union," 1811), and a journal, *Iduna* (1811-'24). It sought its sources of inspiration in the ancient literature and mythology of the North. Foremost among its members, and foremost among all the poets of Sweden, stands Esaias Tegnér (1782-1846). His *Frithiofs Saga*, based upon one of the old semi-historical stories of the Icelandic, is the longest of his works. The popularity of this singularly beautiful poem at home is unequalled, and abroad it has been rendered into many languages, including no fewer than a dozen different versions in German alone. *Azel* is a shorter poem, narrating an incident of the wars of Charles XII., and ranks only second to *Frithiofs Saga*. The *Nattvardsbarn* ("Children of the Lord's Supper"), translated into English by Longfellow, is one of the most successful specimens of hexametric verse in any modern tongue. Of Tegnér's shorter pieces, *Hjälten* ("The Hero"), *Polarresan* ("The Polar Journey"), and *Sång till Solen* ("Ode to the Sun") are reckoned among the best. The historian Geijer was another member of the *Göthiska Förbundet*; his lyrics are original, strong, and clear. There is more novelty and force than good poetic taste in the *Aarne* ("The Gods of the North"), *Tirfing*, and the historical tragedies of P. H. Ling (1766-1839), who is better known out of Sweden as the founder of a new system of medicine or medical gymnastics. Far better in style was C. A. Nicander (1799-1839), author of *Runesvärdet* ("The Runic Sword") and other poems. Influenced by one or other of these two schools, but to a certain extent independent of both, are E. J. Stagnelius (1798-1828), whose dramas, such as *Martyrerna* ("The Martyrs"), epical poems, as *Wladimir*, and minor pieces, are marked by an admirable spirit and great beauty of diction; Erik Sjöberg (1794-1828), better known by his assumed name Vitalis, who, like Nicander and Stagnelius, died just as his powers were ripening into a promising maturity; A. Lindeblad (born 1800), a composer of religious and secular lyrics in the spirit of Tegnér; and A. A. Grafström (born 1790), whose poetical development was strongly influenced by Franzén. The highest rank among living poets is held by Johan Ludvig Runeberg, a native and resident of Finland, in whose *Fänrik Ståls Sägner* ("Ensign Stal's Stories"), a series of patriotic lyrics on the Swedish-Russian war of 1808-'9, are displayed an energy of expression and a depth of poetic thought unknown to Swedish literature since the death of Tegnér. O. W. Böttiger (born 1807), the son-in-law of Tegnér, has written some musical dramas and minor pieces, distinguished by a lively fancy and a cultivated taste. O. P. Sturzenbecker is the author of lyrics and the manner of Heine, and of humorous sketches.

Somewhat later are Von Braun (died 1860), whose humor is striking, but too often broad and coarse; Nybom; C. W. A. Strandberg, whose pseudonymous name is Talis Qualis, and who has translated Byron and written some lyrics of great excellence; Malmström, Säterberg, J. M. Lindblad; Tekla Knös, a poetess, whose claims to fame have been sanctioned by the Swedish academy; G. Silfverstolpe, Wennström, and many others. A series of humorous songs, descriptive of university life, under the title of *Gluntarne*, the words and music by G. Wennerberg, have attained a marked popularity. Tragedies and historical dramas have been written by J. Börjeson (born 1790), one of the *Fogforister*, whose *Eric XIV.* is one of the masterpieces of the Swedish drama; C. E. Hylten-Cavallius, Dahlgren, and Kullberg; and comedies by A. Blanche, Jolin, Cramér, Hedberg, Granlund, Beskow, and others. No romances stand higher than those of three female writers, Fredrika Bremer (born 1802), whose first work (1828) was styled *Teckningar ur Hvardagslivet* ("Sketches of Every Day Life"); E. S. Carlén (born 1810), a prolific and popular authoress of novels of society; and Baroness Knorring (died 1839). All of these are widely known both in Europe and America through numerous translations. Of the imitators of Sir Walter Scott, the highest name is perhaps the learned and versatile V. F. Palmblad (1788-1852), celebrated as a geographer, critic, biographer, and politician of the ultra conservative school, whose *Aurora Königsmark* was one of the earliest readable fictions in Swedish. Equally versatile was C. J. L. Almquist (born 1798), whose tales, and especially a collection called *Törnrosens Bok*, are rich in variety and fancy. Other romancers are Count P. G. Sparre (born 1790); F. Cederborg (born 1784), author of *Ottar Tralling* and *Uno von Träsenberg*, historical fictions of much interest; O. F. Ridderstad (born 1807), an imitator of the Dumas school; Kjellman-Göransson, Zeipel, Bjursten; Wetterberg, a popular writer of sketches and tales under the assumed name of *Onkel Adam*; and G. H. Mellin (born 1803). As translators may be mentioned C. A. Hagberg, author of an accurate and spirited version of the complete works of Shakespeare; Andersson, translator of Goethe; and N. Lovén, who has rendered the poems of Dante and Camoens into Swedish verse. Most of the higher efforts of literature in English, French, German, Italian, and Danish, especially in fiction, have been translated within the last 30 years.

SWEDENBORG, EMANUEL, a Swedish philosopher and religious writer, born in Stockholm, Jan. 29, 1688, died in London, March 29, 1772. He was the son of Jesper Swedberg, bishop of Skara in West Gottland, who had the charge of the Swedish church in England and its American colonies. The family was ennobled in 1719 by Queen Ulrica Eleonora; and thenceforth he assumed the name of Swedenborg, and took his seat with the nobles of the

equestrian order in the triennial assembly of the states. He was in his childhood the subject of deep religious impressions. He received the best education which the times and the country afforded, taking the degree of doctor of philosophy at the university of Upsal in 1709, and afterward travelled in foreign countries. In some of his early productions he displayed much poetical talent, but he was mainly devoted to the studies of mathematics and mechanics. His proficiency in these sciences brought him into intimate association with Christopher Polheim, who seems to have enjoyed the unbounded confidence of Charles XII. Swedenborg was in this way introduced to the special notice of Charles, by whom he was appointed in 1716 assessor of the royal board of mines; his commission stating that "the king had a particular regard to the knowledge he possessed in the science of mechanics, and that it was his pleasure that he should accompany and assist Polheim in constructing his various mechanical works." In 1718 he turned his mechanical skill to practical account at the siege of Frederickshald, when, by means of machines of his own invention, he contrived to transport several large vessels, over hills and valleys, a distance of about 14 miles. About this time he published several small works: a proposal for fixing the value of coin, and determining the measures of Sweden, so as to suppress fractions and facilitate calculations; a treatise on the position of the earth and planets; and some others. In 1721 he again travelled, with special reference to preparing himself for the duties of his office of assessor. During this year he published in Latin at Amsterdam six small philosophical treatises; a new edition of one of which, "A Practical Method of finding the Longitude of Places on Land and at Sea by Lunar Observations," was published by him late in life. In 1723 he published at Leipsic "Miscellaneous Observations connected with the Physical Sciences," parts i.—iii., and at Hamburg part iv., principally on minerals, iron, and the stalactites in Bauman's cavern. In 1733 he again went abroad, and in 1733-'4 published in Latin at Dresden and Leipsic his "Principia, or the First Principles of Natural Things, being new Attempts toward a Philosophical Explanation of the Elementary World" (3 vols. fol.), produced in elegant style, with copious engravings, at the expense of the duke of Brunswick. In 1740 he published at Amsterdam "The Economy of the Animal Kingdom;" and in 1744 and 1745, at Amsterdam and London, "The Animal Kingdom," and "The Worship and Love of God." These were the last of Swedenborg's philosophical works. His reputation was now established as one of the profoundest thinkers of the age, and his acquaintance and correspondence were sought by the most distinguished scholars in Europe. Count Hopken, senator, and at one time prime minister of Sweden, says of him that "he was with-

out contradiction the most learned man in my country." In 1724 the consistory of the university of Upsal invited him to accept the office of professor of pure mathematics, because, as they said, "his acceptance would be to the advantage of the students, and the ornament of the university;" which, however, he declined. In 1729 he was admitted a member of the academy of sciences of Upsal, and in 1734 was made a corresponding member of the academy of sciences of St. Petersburg. He was among the earliest members of the royal academy of sciences at Stockholm, and his portrait is in the hall of the academy as one of its past presidents, near that of Linnæus, who was one of its founders. The most important of the works above mentioned have been recently translated into English, and the English reader has been surprised at their vast amount of profound learning and original thought. It is confidently asserted by scientific men who have given them the most careful study, that a number of important discoveries in the different departments of science, which have made other names illustrious, were anticipated by him. These works afford evidence of a remarkably well balanced mind, in which the beautiful and the practical, poetry and mathematics, were harmoniously blended together. His writings always breathe a pure devotional spirit, and persons to whom he was most intimately known, of high and low rank, bear testimony to the excellence of his private character. The following rules of life were found noted down in several of his manuscripts, evidently intended for private use, as they are nowhere met with in his published works: "1. Often to read and meditate on the Word of God. 2. To submit every thing to the will of Divine Providence. 3. To observe in every thing a propriety of behavior, and always to keep the conscience clear. 4. To discharge with fidelity the functions of my employments and the duties of my office, and to render myself in all things useful to society."—Such, as we learn from the most authentic sources, was Swedenborg in the year 1745, at the age of 57, in the full maturity of his powers and his fame. In this year, as he assures us, "he was called to a new and holy office by the Lord himself, who manifested himself to him in person, and opened his sight to a view of the spiritual world, and granted him the privilege of conversing with spirits and angels." No one at all conversant with Swedenborg's writings and character can doubt his sincerity. He regarded his previous studies as having answered their great purpose, as a means of preparation for the far higher use in which he was to be henceforth employed, and in his subsequent writings makes no allusion to his philosophical works. As his office was mainly to reveal the spiritual sense of the Sacred Scriptures, he thenceforth made these his constant and exclusive study. He now commenced the study of the Hebrew, with which he made himself acquainted, that he

might read the Old Testament in the original language. It is said that no other books were seen in his study, except the Hebrew and Greek Bibles, and the indexes to his own works which he used for the convenience of reference. There was not the slightest appearance of enthusiasm, but he proceeded in the most deliberate manner; the divine assistance, which he said was vouchsafed to him, not seeming in the least to supersede the exercise of his own mental powers. Neither does he appear to have been in the least elated by his exalted office, but more humble. "This knowledge," he said, "is given to me from our Saviour, not for any particular merit of mine, but for the great concern of the salvation and happiness of all Christians." There was no appeal to the weakness or credulity of the ignorant or the vulgar. Indeed, there was no attempt to make proselytes at all. He had no desire to be the head of a sect, or to connect his own name with the new church which he said was about to be established. He evidently felt as if he were addressing posterity rather than those of the present age; and his works, as they left the press in Latin folio volumes, were distributed by him gratuitously to the universities of Europe, and among the learned, especially the clergy.—In 1747 he asked and obtained leave of Frederic, then king of Sweden, to retire from the office of assessor, a place which he had filled for 31 years. He also requested that one half of his salary should be continued to him, which was readily granted. He says: "My sole object in this resignation was, that I might be more at liberty to devote myself to that new function to which the Lord had called me. On resigning my office, a higher degree of rank was offered me, but this I declined lest it should be the occasion of inspiring me with pride." After 4 years of labor and preparation, the first volume of his theological works appeared in 1749, under the title of *Arcana Cælestia*, or "Heavenly Arcana, which are contained in the Sacred Scripture, or Word of the Lord, laid open, beginning with Genesis, together with relations of Wonderful Things seen in the World of Spirits and the Heaven of Angels." He was fully aware of the incredulity with which the work would be received with very few exceptions, as he himself tells us. "It is not unknown to me," he says, "that many will say that a man can never speak with spirits and angels while he lives in the body; and many that it is fantasy; others that I relate such things to gain credit, others other things; but I do not hesitate on this account, for I have seen, have heard, have touched." It appears by the original advertisement of the publisher, that he paid £200 for the publication of the first volume of the *Arcana*, and also advanced £200 for the second, and gave direction that all receipts from the sales of the work should be given "toward the charge of the propagation of the gospel." This work, like most of his other theological works, was

published without the name of the author. The publication of the *Arcana Cælestia*, commenced in London in 1749, was completed in 1756, in 8 vols. 4to., setting forth the spiritual sense, in a connected series, of Genesis and Exodus, with explanations of the signification of numerous other passages, which are introduced from other parts of the Scriptures, together with "relations of things seen and heard in the spiritual world," which are found between the chapters. This is much the largest of his theological works. Like all the rest, it is written in good mediæval Latin, divided into distinct paragraphs, all of which are numbered, having copious references from one paragraph to others, in the same or different works, where the subject is treated of. Remarkable method and consistency prevail throughout the whole. In 1758 Swedenborg was again in London, where he published the following named works: 1, "Account of the Last Judgment and the Destruction of Babylon, showing that all the predictions in the Apocalypse are at this time fulfilled, being a relation of things heard and seen;" 2, "Concerning Heaven and its Wonders, and concerning Hell, from things heard and seen;" 3, "On the White Horse mentioned in the Apocalypse;" 4, "On the Planets in our Solar System, and on those in the Starry Heavens, with an Account of their Inhabitants and of their Spirits and Angels;" 5, "On the New Jerusalem and its Heavenly Doctrine, as revealed from Heaven." In 1763 he published at Amsterdam: 1, "The Doctrine of the New Jerusalem respecting the Lord;" 2, "The Doctrine of the New Jerusalem respecting the Sacred Scripture;" 3, "The Doctrine of the New Jerusalem respecting Faith;" 4, "The Doctrine of Life for the New Jerusalem;" 5, "Continuation respecting the Last Judgment and the Destruction of Babylon;" 6, "Angelic Wisdom concerning the Divine Love and Wisdom." In 1764 he published at the same place "Angelic Wisdom concerning the Divine Providence," and in 1766 "The Apocalypse Revealed." He had nearly prepared for the press a much larger work than that last mentioned, in explanation of the Apocalypse, under the title of "The Apocalypse Explained," which he seems to have laid aside for the other. This work has been published since his death, in 4 vols. 4to., containing about half as much matter as the *Arcana Cælestia*. In 1768, at the age of 80, he proceeded to Amsterdam, where he published the work entitled "The Delights of Wisdom concerning Conjugal Love; after which follow the Pleasures of Insanity concerning Scortatory Love." This was followed in 1769 by the "Brief Exposition of the Doctrine of the New Church," and by the little work entitled "The Intercourse between the Soul and the Body," usually known as the "Treatise on Influx." His last work was published at Amsterdam in 1771, under the title of "The True Christian Religion, containing the Universal Theology of the New Church

foretold by the Lord in Daniel, chap. xii. 13, 14, and in the Apocalypse, chap. xxi. 1, 2." This work contains, as its name implies, a complete summary of the doctrines of the New Church. In addition to the works mentioned, he left voluminous manuscripts, which after his death were deposited in the library of the royal academy of sciences at Stockholm, many of which have since been edited and published by Dr. J. F. I. Tafel, professor and librarian in the university of Tübingen. A general summary of the doctrines contained in Swedenborg's theological writings may be found in the article **NEW JERUSALEM CHURCH**. By far the greater part of them are devoted to the explanation of the spiritual sense of the Sacred Scriptures, and all may be said to be directly or indirectly connected with that subject. After the publication of the "True Christian Religion," Swedenborg went to London, where he seems to have been employed in the preparation of a supplement to that work, entitled "The Coronis or Appendix to the True Christian Religion." On Christmas eve, 1771, he was struck with apoplexy, from which he partially recovered, and remained in complete possession of his mental faculties till the time of his death.—The number of those who received the doctrines promulgated by Swedenborg during his life was very small, but among them were men, both in his own country and in England, distinguished alike for their learning and the purity of their lives, who enjoyed the opportunity of intimate relations with him. Of this number may be named Count Andrew John von Hopken, and Dr. Gabriel Andrew Beyer, professor of Greek literature and member of the consistory of Gothenburg, in Sweden; and in England, the Rev. Thomas Hartley, rector of Winwick in Northamptonshire, who was the first translator into English of some of his theological works, of which a copious index was made by Dr. Beyer. Dr. Hartley visited Swedenborg in his last sickness, a short time before his death, in company with Dr. Messiter, a distinguished physician in London, and asked him "to declare whether all he had written was strictly true, or whether any part or parts thereof were to be excepted;" to which he replied with warmth: "I have written nothing but the truth, as you will have it more confirmed hereafter all the days of your life, provided you always keep close to the Lord, and faithfully serve him alone, in shunning evils of all kinds as sins against him, and diligently search his Word, which from beginning to end bears incontestable testimony to the truth of the doctrines I have delivered to the world." There are a number of well authenticated cases in which Swedenborg communicated facts, his knowledge of which is deemed by the receivers of his doctrines wholly inexplicable without supposing him to have had communication with the spiritual world. He never sought however to make any demonstrations of this kind, nor does he anywhere in his pub-

lished works appeal to them as evidence of his mission or of the truth of his doctrines, or even mention them. They seem to have been mere incidents of his life. Swedenborg enjoyed the friendship and confidence of the reigning monarchs of Sweden, from Charles XII. onward to the time of his death. His character, however, was marked by the constant absence of all desire for personal distinction or self-aggrandizement, and his habits of life were of the most simple and unostentatious kind. He was never married.—Several lives of Swedenborg have been published, among which in English are the following: "Life of Emanuel Swedenborg, with some Account of his Writings," by B. F. Barrett (New York, 1841); "Biographical Sketch of Emanuel Swedenborg, with an Account of his Works," by Elihu Rich (London, 1849); "Emanuel Swedenborg, a Biography," by James John Garth Wilkinson (London and Boston, 1849); Hobart's "Life of Swedenborg" (Boston, 1831 and 1862). The last named work has passed through many editions, and is generally regarded by the receivers of Swedenborg's teachings as the fullest and most authentic of these biographies.

SWENKENSUND, or **SVENKSUND**, a sound of the gulf of Finland, lying between Viborg and Frederiksham. Gustavus III., king of Sweden, was defeated here by the prince of Nassau-Siegen in 1789, and conquered him there in turn the succeeding year. On the coast of the sound is the town of Svenksund, with about 1,900 inhabitants.

SWETT, **JOHN APPLETON**, M.D., an American physician, born in Boston in Dec. 1808, died in New York, Sept. 18, 1854. He was graduated at Harvard college in 1828, and commenced immediately a course of medical study in the office of Dr. Jacob Bigelow of Boston, attended the lectures of the Harvard medical school, and took his degree of M.D. in 1831. Soon afterward he opened an office in New York city, and became connected with the city dispensary. The death of his father having put him in possession of a small property, he resolved to prosecute his medical studies further in the hospitals of Paris, and accordingly sailed for Europe June 12, 1835, and spent nearly the whole of the next 17 months in close clinical study, giving his attention principally to the clinical lectures of the celebrated Louis at La Pitié. In the spring of 1838 Dr. Swett associated himself with several other young physicians of the city in the delivery of an extra-academical course of lectures, his topic being "Diseases of the Chest." This association, known at the time as the Broome street school of medicine, was maintained through two years, courses of lectures being delivered in the spring and autumn. In 1841 several of its members, including Dr. Swett, commenced

a spring course of lectures in the college of physicians and surgeons in Crosby street. His lectures, which were delivered from brief notes, were reported in the "New York Lancet," and gave him at once a high reputation. For some years he confined his practice mainly to diseases of the chest. About 1840 he was associated with Dr. Watson as editor of the "New York Journal of Medicine," the organ while it existed of the New York medical and surgical society. In 1842 he was elected one of the physicians of the New York hospital, and in connection with his duties there began to make very thorough and careful researches into diseases of the kidneys, not neglecting however his former speciality of diseases of the chest. His investigations on albuminuria and other diseases of the kidney were protracted through the whole remainder of his life. When failing health compelled him in 1850 to visit Europe, he devoted most of his time while there to the study of microscopy with the French physician Robin; and in 1852 he published his "Treatise on Diseases of the Chest." In 1853 he was appointed professor of the theory and practice of medicine in the medical department of the university of the city of New York, and delivered a course in the spring of the same year, and another in the ensuing winter.

SWIETEN, GERARD VAN, a Dutch physician and author, born in Leyden, May 7, 1700, died at Schönbrunn, Austria, June 18, 1772. He was a favorite pupil of Boerhaave, and after a few years' practice was elected to the chair of medicine in the university of Leyden; but his adherence to the Roman Catholic faith, and the sternness and inflexibility of his character, made him so unpopular that he was compelled to resign his professorship. In 1745 he was called to Vienna as physician-in-chief to the empress Maria Theresa, and professor of medicine and anatomy. He was subsequently appointed director of the imperial library, perpetual president of the faculty of medicine at Vienna, director of the medical affairs of the empire, and censor of books. His great medical work, *Commentarii in H. Boerhaavii Aphorismos de Cognoscendis et Curandis Morbis* (5 vols. 4to., Leyden, 1741-'72), is still regarded as of great value for its careful observation, while it has served as the source of many smaller medical works by other authors. He also wrote in French a treatise on military medicine, and left a posthumous *Essai sur les épidémies* (1782).

SWIFT, the general name of the *cypselids*, a sub-family of birds generally placed among the swallows, but by some recent German ornithologists ranked as a separate family coming near the humming birds, on account of certain anatomical peculiarities, and particularly of the absence of singing muscles in the lower larynx. The swifts resemble the swallows in habits and in their general form; the bill is more suddenly curved, unprovided with bristles at the base; nostrils very large, oblong, with an elevated margin; wings extremely long,

curved, and narrow, with 10 primaries; tarsi short and weak, and more or less feathered; toes short and thick, and all 4 are or may be directed forward, as in no other bird; claws strong and curved; 10 feathers in the tail. They are very swift and graceful fliers, feeding exclusively on insects which they capture on the wing; they are migratory like the swallows, but do not mingle with them and are less hardy; most of them nestle in hollow trees, holes in buildings, or crevices in rocks; some species rear 2 or 3 broods in a season.—In the genus *cypselus* (Illig.) the 2d quill is the longest, and the tarsi are feathered to the base of the toes; it is peculiar to the old world. The common European swift or black martin (*C. apus*, Illig.) is 7½ inches long, with a forked tail; it is blackish brown above with a green gloss, and the throat grayish white. It appears in Great Britain in May, departing in August; great numbers are seen morning and evening, darting about after insects, uttering a shrill scream, the only note; the food consists of very small insects, which are collected in considerable quantity in the mouth, retained by a viscid secretion, before they are swallowed; the extreme shortness of the legs renders walking and rising from a flat surface almost impossible, but the stout toes and sharp claws form admirable clinging organs for climbing in and out the holes where the nests are placed; the nest is bulky and clumsily made, and the eggs, 2 or 3, are pure white; only one brood is raised in a season. The white-bellied swift (*C. melba*, Illig.) is 8½ inches long, grayish brown above and white below, the legs covered with brown feathers; it is common in southern Europe, especially in mountainous regions.—In the genus *chatura* (Steph.) or *acanthylis* (Boie) the tail is very short, about ½ of the wings, slightly rounded, the shafts stiffened and extending beyond the feathers as rigid spines; 1st quill the longest; legs covered with a naked skin. The species are found in North and South America, Australia, and the East Indies; they live in flocks, and breed usually in holes of trees, but sometimes in crevices in rocks, and the eggs are usually four. The American swift or chimney swallow (*C. pelagica*, Steph.) is 5½ inches long and 12½ in alar extent; it is sooty brown above with a greenish tinge, a little paler on the rump, and considerably lighter from the bill to the breast; it is found from the eastern states to the slopes of the Rocky mountains, arriving from the south by the end of April or beginning of May, and departing during the first half of September. This species naturally makes its nest in hollow trees, but in the neighborhood of man builds in such chimneys as are not used in summer for fires; the nest is made of twigs snapped off from a dead tree during flight, fastened together by viscid saliva, without soft lining, and is generally placed from 5 to 8 feet from the entrance; the eggs are pure white. They pass in and out the chimney with great

rapidity, making a whirring sound like distant thunder; there are sometimes 200 in a single chimney; if by chance the nest be loosened by rains and fall, the young cling to the sides of the chimney with their sharp claws; the scratching and rumbling have a very strange sound at night, and many a traveller in thinly settled regions, unaccustomed to these nocturnal disturbances, has been terrified by supposed unearthly noises in the chimney. They do not alight on trees or on the ground.—In the genus *collocalia* (Gray) the bill is very small, wings very long, tail moderate and nearly even, and tarsi naked. The esculent swift or swallow (*C. esculenta*, Gray) is the principal maker of the celebrated nests so highly esteemed by the Chinese as articles of food; these consist of a mucilaginous substance secreted by the greatly developed salivary glands, more or less mixed with fragments of grass and similar materials, and are attached to the surface of rocks in almost inaccessible caves in the islands of the East Indies; the older writers supposed the nests to be made of sea weeds macerated in and rejected from the stomach. These nests are built by 3 or 4 species, and are collected in large quantities, forming an important article of commerce in China; for an account of the mode of collecting, value of the product, and uses to which the nests are put, see BIRDS' NESTS, EDIBLE. The eggs are 2 in this genus. There are many other species of swifts, both in the old world and the new.

SWIFT, JONATHAN, dean of St. Patrick's, a British author, born in Dublin, Nov. 30, 1667, died there, Oct. 19, 1745. He was of purely English descent; his father, Jonathan Swift, emigrated from Herefordshire, and dying in embarrassed circumstances before the birth of his son, left his family dependent upon his brother Godwin. The son's career at Trinity college, Dublin, which he entered in his 15th year, was obscure and unhappy, the logic of the schoolmen, then the beginning and end of the curriculum at Dublin, being distasteful to him, and his pecuniary circumstances such as to prevent him from associating on an equal footing with those he considered his equals. His neglect of the ordinary college studies resulted in his failure at his first application to obtain his bachelor's degree, which was at length conferred upon him in Feb. 1685, *speciali gratia*. This disgrace, however, seems to have aroused in him no other feelings than contempt and resentment; and during his subsequent residence at the university he showed himself so indifferent to academic rules and discipline as to incur within two years no fewer than 70 penalties and censures, beside being compelled to crave public pardon of the junior dean, Dr. Owen Lloyd. In 1688 he left Dublin on a visit to his mother, who was then living in Leicester, England, dependent on the bounty of her relations, one of whom was the wife of Sir William Temple; and a few months later he entered the family of that statesman in the

capacity of private secretary. Abandoning his former careless and idle habits, he now employed his leisure hours in study, and from daily intercourse with his patron acquired a familiarity with public affairs which gave to his subsequent political pamphlets a very different character from those produced by mere men of letters. But to one who like Swift was at heart the most haughty, despotic, and sensitive of men, the position of secretary, with a salary of £20, was a heavy price to pay for the advantages he derived; and in after years he alluded with bitterness to the humiliations he endured under the roof of Sir William Temple, whom he was in the habit of addressing with the obsequiousness of a lacquey or a beggar, and a sharp word or cold look from whom sufficed to make him miserable for days. Much of the acerbity which subsequently characterized his intercourse with people of every degree may doubtless be ascribed to this enforced subserviency, aptly likened by Macaulay to the tameness with which a caged tiger submits to the keeper who brings him food. At Moor Park, Temple's seat in Surrey, Swift had frequent opportunities of seeing William III., who was in the habit of consulting the retired statesman on public matters; and on one occasion he was deputed by his patron to persuade the king to consent to the bill for triennial parliaments. The latter failed to be convinced by the arguments of the Irish secretary, of whose intellectual endowments he could have formed no flattering estimate, if his offer to make him captain of a troop of horse may be considered a criterion. In 1692 Swift took his master's degree at Oxford, and two years later, finding Temple unwilling to make any definite provision for him, he renounced his employment and left Moor Park in a pique, intending to take orders in Ireland and look for preferment from some other source. His mortification may be conceived when he discovered that a certificate from Sir William was necessary to enable him to obtain orders; and the letter in which he solicits it, praying that "Heaven would one day allow him the opportunity of leaving his acknowledgments at the feet" of his offended patron, is a curious illustration of the readiness with which he could humiliate himself for the purpose of furthering his own interests. In Oct. 1694, he was ordained, and soon after received the prebend of Kilroot, in the diocese of Connor; but a few months served to weary him of the life of a rural incumbent, and having received a kind letter from Sir William Temple, who felt the want of his services, he gladly returned to his old position and to the elegant retirement and literary resources of Moor Park. He was thenceforth treated with more consideration, and upon the death of Sir William in 1698 received a legacy, coupled with the task of editing his posthumous works, which were published in London in 1699, with a memoir of Temple and a dedication to the king. Although

a promise of a prebend of Westminster or Canterbury had been held out to Swift, his claims, unsupported by the influence of Temple, were overlooked, and he was obliged to content himself with the position of chaplain and secretary to Lord Berkeley, one of the lords justices of Ireland, whom in 1699 he accompanied to Dublin. A person named Bush succeeded in supplanting him in the office of secretary, and subsequently in securing the presentation to the rich deanery of Derry, which Berkeley had promised to Swift; whereupon the latter, exclaiming: "God confound you both for a couple of scoundrels!" threw up his chaplaincy in a rage. As some sort of compensation for this disappointment, Berkeley gave him the vicarage of Laracor and several other livings, amounting altogether to nearly £400 a year. In 1700 Swift entered upon the discharge of his parochial duties at Laracor; and about the same time Esther Johnson, with whom he had contracted a tender friendship while they were both dependants of Sir William Temple, came at his invitation, accompanied by Mrs. Dingley, a friend, to reside in the neighborhood. At Moor Park Miss Johnson had passed for the daughter of Sir William's steward; but her personal resemblance to Sir William himself and a variety of other concurring circumstances have rendered it tolerably certain that she was his illegitimate offspring. Younger by 15 years than Swift, who appears to have assisted in her education, she gave him from their earliest acquaintance a love which never wavered in its warmth or constancy; and as the "Stella" of his poems and familiar letters, her name is inseparably associated with his own in a sad and mysterious history. During his previous residence in Ireland Swift had become enamored of a Miss Jane Waryng, the sister of an old college friend; but his offer of marriage was declined by her on considerations of health. Subsequently the lady herself, whom Swift addressed as Varina, reopened negotiations, and received from her former admirer a letter of acceptance, containing such unreasonable and insulting conditions, that further intercourse or correspondence was cut short. Swift's conduct as a parish priest was creditable to himself and his calling; and, though laboring in behalf of an establishment which had neither the respect nor the affection of the people, and with every inducement to neglect his duties, he held regularly three services a week, the average attendance at which rarely exceeded half a score of persons, and in his sermons, characterized by himself as "pamphlets," he preached the doctrines of his church to the best of his ability. In 1701 he made the first of a number of annual visits to England, and published anonymously in London his "Discourse of the Contests and Dissensions between the Nobles and Commons of Athens and Rome," vindicating the conduct of the whig leaders, Somers, Halifax, Harley, and Portland, in respect to the partition treaty, and which was

generally attributed to Somers himself or Burnet. He avowed the authorship in the succeeding year, and was immediately admitted into the society of the statesmen he had defended, and into that of Addison, Steele, Arbuthnot, and others of the leading wits of the time. With this period commences Swift's career as an author, although he did not engage actively in writing political pamphlets, his most numerous and in many respects most characteristic performances, until several years later. Some trifles in prose and verse written for the amusement of his friends had already shown him to possess a choice and original vein of humor, but he had signally failed in a series of "Pindaric Odes," his only serious effort in the higher walks of poetry, which called forth from Dryden, who was his kinsman, the remark: "Cousin Swift, you will never be a poet." In 1704 appeared his "Battle of the Books," written at Moor Park in 1697, in support of Sir William Temple's views in the controversy respecting the relative merits of ancient and modern learning. This was succeeded by the "Tale of a Tub," a wild and witty satire upon the Roman Catholics and dissenters, with an occasional allusion to the errors of the church of England, the high church party of which it was his object to exalt. This work had also been completed in manuscript several years previous, and is in every respect one of Swift's most perfect and labored efforts; but it proved an insurmountable obstacle to his hopes of high preferment. After an interval of several years he published in 1708 his "Argument against the Abolition of Christianity," a masterpiece of grave irony; "Sentiments of a Church of England Man in respect to Religion and Government;" the humorous attacks on Partridge the almanac maker, entitled "Predictions for 1708 by Isaac Bickerstaff;" and "Letters on the Sacramental Test," in which he enunciated views on the relaxation of the restrictions upon the dissenters very different from those entertained by the whigs, and which may partially explain his subsequent abandonment of that party. In 1709 he published the only work to which he ever attached his name, "A Project for the Advancement of Religion," dedicated to Lady Berkeley. About this time some efforts were made by Swift's political friends, who began at length to appreciate the value of his services, to secure his preferment; and among other plans proposed was one to make him bishop of Virginia, with a general authority over all the clergy in the American colonies. The public scandal which the appointment of the author of the "Tale of a Tub" to this office would have created probably operated against him on this as on other occasions, and he received nothing beyond the flatteries of men in office and abundant invitations to dinner; while his friend Addison, who had done no more for the whigs than himself, was loaded with solid benefits. Smarting under a sense of neglect, and incensed by the cold reception which Godolphin accorded to

his repeated applications for an increased endowment of the Irish clergy, he wavered for a while between whigs and Tories, and finally, in Oct. 1710, went over to the latter, by whom he was received with open arms. Harley and St. John became his warm friends, and in the exultation of the moment he wrote to Stella in Ireland: "I stand with the new people ten times better than ever I did with the old, and forty times more caressed." Swift immediately entered the arena of political controversy, and the "Examiner," a weekly paper established by St. John and others in the interest of the ministry, was for more than half a year the vehicle for bitter attacks from his pen upon prominent whig statesmen. His powerful pamphlet on the "Conduct of the Allies," published in Nov. 1711, and which had a considerable influence in bringing the war to a close, raised his reputation to the highest pitch, and he found himself courted by men of rank and station, and in a position to confer substantial favors upon deserving persons, which he is known to have done in a number of instances. But he himself, while dictating, as Dr. Johnson has observed, the political opinions of the English nation, remained unrewarded; and the efforts of Harley and St. John, now become Lords Oxford and Bolingbroke, aided by Mrs. Masham, were unavailing to procure him a bishopric, the queen, under the advice of Archbishop Sharp and other prelates, positively refusing him any high preferment. Upon the failure of an application in his behalf for the vacant see of Hereford, through the opposition of the duchess of Somerset, whom he had lampooned, Swift threatened to withdraw his support from the ministry, but was pacified by his appointment, in Feb. 1713, to the deanery of St. Patrick's cathedral, Dublin, the income of which amounted to £700. Returning to Ireland, after an absence of nearly 8 years, he had scarcely got settled in his deanery when he was summoned back to England to reconcile the difficulties between Oxford and Bolingbroke, which threatened to break up the cabinet. About this time he wrote his "Public Spirit of the Whigs," which reflected so bitterly upon the Scottish nation and nobility that the latter in a body presented a complaint to the queen. In June, 1714, appeared his "Free Thoughts on the State of Public Affairs;" and upon the dismissal of Oxford a few weeks later he gave a noble proof of the strength of his friendship by declining the flattering overtures of Bolingbroke, in order to be of service to the disgraced minister. The death of the queen immediately after this event and the overthrow of the Tories sent Swift back to Ireland, where he remained during the next 12 years.—Ever since the arrival of Stella in Ireland his relations with her had been of the most intimate and affectionate character. They saw each other daily when at home, corresponded regularly when apart, and during his frequent absences she superintended his house-

hold, indifferent apparently to the scandal which her equivocal position provoked. Soon after his formal adhesion to the Tories Swift had become intimate in London in the family of a Mrs. Vanhomrigh, whose eldest daughter, Esther, a spirited, intelligent, and accomplished girl, kindly noticed and occasionally directed by him in her studies, conceived so violent a passion for her tutor as to be induced to propose marriage to him. The offer was declined, but, whether from real interest in Miss Vanhomrigh (who under the name of Vanessa has gained a celebrity as sad and romantic as that of her companion in misfortune, Stella), or from gratified vanity, he neglected to discourage her advances. Upon the death of her mother, Vanessa removed in 1714 to Ireland to be near Swift, who thus found himself involved in a pitiable dilemma, with two women equally devoted to him, and neither of whom he was willing to marry, notwithstanding he had protested to Stella that he "loved her better than his life a thousand million of times." Vanessa, ignorant of Swift's relations with Stella, and absorbed in her own passion, endured his coldness or reproaches without a murmur, in the hope of one day becoming his wife; but to Stella, who had waited patiently for more than 15 years to have this justice done her, the idea of being replaced in Swift's affections by a rival was intolerable, and at her solicitation he is said to have finally consented to a private marriage with her, which took place in the garden of the deanery in 1716. At his express stipulation, however, the matter was kept secret; and as the relations of the parties remained unchanged, and they were never known to meet but in the presence of a third person, it was at the best but a nominal union, and throughout her life his wife commonly passed for his mistress. In 1717 Vanessa retired with her sister to Marley abbey near Celbridge, and for several years lived in deep seclusion. During the illness of her sister in 1720 Swift renewed his visits, each of which Vanessa commemorated by planting a laurel in the garden where they met; but at length, tormented by suspicion and impatience, she wrote to Stella to ascertain the nature of her connection with Swift. The latter, getting possession of the letter, rode directly to Marley abbey, flung it upon the table before Vanessa with a frown which struck her dumb with terror, and instantly departed. The unhappy woman survived this shock but a few weeks, and Swift, overcome by shame and remorse, retired for two months to solitude in the south of Ireland. After her death appeared his poem entitled "Cadenus and Vanessa," describing the manner in which Swift (personified as Cadenus, an anagram of *Decanus*, the dean) received the early advances of Miss Vanhomrigh. Five years later Stella herself dropped into the grave, without any public recognition of her marriage, and with her departed what Thackeray calls "the good angel of his life; when

Stella's sweet smile went, silence and utter night closed over him." Of the various reasons assigned for his conduct toward these two women, of all persons in the world the most devoted to him, that which ascribes it to the malady which finally overwhelmed his reason is the most charitable.—For several years after Swift's return to Ireland he wrote little; but finding Irish affairs likely to prove a fit cover for attacks upon the existing whig government, he produced in 1720 a "Proposal for the Universal Use of Irish Manufactures," followed in 1728 by the celebrated "Drapier's Letters," in opposition to the royal grant authorizing Wood to coin £108,000 in halfpence and farthings for general circulation in Ireland. The author by no means confined himself to the single grievance here alluded to, but denounced the whole system of government in Ireland with a vigor and point which aroused a powerful popular feeling in his favor. His effigy was produced on signs and medals, and distributed broadcast in innumerable prints; and so powerful became his influence with the lower classes that Walpole, when meditating legal proceedings against the author, was told that it would require 10,000 men to arrest him. It may be doubted, however, whether Swift, proud of his unmixed English blood and looking upon the aboriginal inhabitants of Ireland as a servile and alien caste, really valued the popularity which he enjoyed. But with all his affected contempt for the land of his birth, he frequently betrays an instinctive yearning toward it, which has been likened to that felt by the inferior animals for their young. In 1726 appeared his "Gulliver's Travels," the most original and extraordinary of all his productions, and that by which he will be known while the language lasts. Of these wonderful satires on human nature and society Masson observes: "Schoolboys who read for the story only, read Gulliver with delight; and our literary critics, even while watching the allegory and commenting on the philosophy, break down in laughter, from the sheer grotesqueness of some of the fancies, or are awed into pain and discomfort by the ghastly significance of others." In 1726 and 1727 he made visits to England, renewing his intimacy with Pope, Gay, Bolingbroke, Arbuthnot, and others of his early friends; but after the death of Stella he never left Ireland, notwithstanding he was strongly urged to exchange his deanery for a living of less value and importance in Berkshire. His pride revolted against the sacrifice of dignity which this step would involve, and he clung to Ireland, complaining bitterly to Bolingbroke that he should be compelled to die there "in a rage, like a poisoned rat in a hole." For several years he wrote with vigor and increasing bitterness on Irish affairs, and amused himself with composing verses, the humor of which is more than equalled by the fierceness and obscenity of the satire; but by the year 1736 his health became so undermined by frequently recurring attacks

of deafness and vertigo, to which he had been subject from an early period of his life, as to preclude further literary labors. His infirmities rapidly increased after this, and in a corresponding degree his memory and intellect decayed. In the latter part of 1740 his memory almost entirely left him, and frequent fits of passion at length terminated in furious lunacy. This subsided in 1742, and he passed the last 3 years of his life in a condition of speechless torpor, tenderly cared for by his cousin, Mrs. Whiteway, who had undertaken the charge of his household. His brain was found loaded with water, and it is supposed that an operation, if it could not have prolonged life, might have restored his reason. He was interred in the cathedral, amid extravagant demonstrations of popular respect, and the tablet which marks his place of sepulture bears the following characteristic inscription written by himself: *Hic depositum est corpus Jonathan Swift, S. T. P., hujus ecclesie cathedralis decani: ubi sacra indignatio ulterius cor lacerare nequit. Abi, viator, et imitare, si poteris, strenuum pro virili vindicem. Obiit, &c.* With a presentiment of his fate he had bequeathed the bulk of his property, amounting to £10,000, to found a hospital for insane persons.—In person Swift was tall and well made, with a swarthy complexion, and a cast of face that would have been heavy but for the expression communicated to it by the eyes, which Pope describes as "azure as the heavens." Under the influence of anger his features assumed an austerity which awed and frightened most persons. His character, seemingly made up of paradoxes, is still an enigma to many. Economical almost to the verge of parsimony, he reserved a third of his income for charities; brutal, overbearing, and coarse in his manners, he was constantly performing acts of kindness in private; assuming in the treatment of religious subjects a levity of manner which subjected him to the charge of irreverence, he was at heart reverent and pious; indifferent generally upon whom the lash of his satire descended, and having hosts of bitter enemies, he possessed friends who almost idolized him; honest and straightforward in his intentions, and sincerely hating cant, he "bound himself to a lifelong hypocrisy;" and despising women for their intellectual dependence upon man, and frequently grossly insulting them, he yet loved a woman with an exclusiveness and earnestness for which he has never perhaps received full credit. An intense and arrogant desire for power and notoriety characterizes every prominent action of his life. "All my endeavors from a boy to distinguish myself," he writes to Bolingbroke, "were only for want of a great title and fortune, that I might be used like a lord by those who have an opinion of my parts—whether right or wrong, it is no great matter;" and it may be supposed, after this humiliating confession, that the scruples which he at first honestly entertained, and probably never relin-

quished, as to the propriety of entering the church merely for support, were readily silenced. "But having put the cassock on," says Thackeray, "it poisoned him; he was strangled in its bands. He goes through life tearing like a man possessed with a devil;" and to the consciousness of the false part he was enacting and of the sordid motive which guided his literary labors, may doubtless be ascribed much of the suffering of the man who was accustomed to observe the anniversary of his birth as a day of mourning, and whom Archbishop King once called "the most unhappy on earth." He is preëminently the British satirist of his age, reflecting in all his writings what Masson calls "the mad, the obscene, the ghastly, the all but infernal and yet infinitely sorrowful humor" of Rabelais, with a genius peculiarly his own. Of real elevation or sympathy with what is beautiful or sublime he seems to have been utterly destitute, and his poetry, written principally in the octosyllabic verse cultivated by Prior and Gay, though remarkable for ease and felicity of expression and rhyme, as also for its peculiar and imitable humor, is frequently coarse and indecent beyond that of any other writer of the time, the author apparently dwelling with a morbid pleasure upon images of pure physical disgust and loathsomeness. It is but just however to add that his grossness is always repulsive, not seductive; and that the most offensive pieces were written at a period of his life when disease and despair had begun to obscure his mental faculties.—Some posthumous works of Swift were published long after his death, including "A History of the four last Years of Queen Anne," "Polite Conversation," a satire on the frivolities of fashionable life; and "Directions for Servants." A complete edition of his writings was published in 19 vols. by Sir Walter Scott, whose biography of him is still the standard one. That by Dr. Johnson, in his "Lives of the Poets," reflects too closely the dislike which the biographer always entertained for Swift. There is also a copious life by Thomas Sheridan, and an account of his latter years by Dr. Wilde of Dublin, written on the occasion of the remains of Swift and Stella being exhumed, during some repairs in St. Patrick's cathedral, in 1835. The character of Swift is also the subject of an elaborate and in some respects unnecessarily severe essay by Thackeray, included in his "British Humorists."

SWIFT, JOSEPH GARDNER, an American general and civil and military engineer, born in Nantucket, Mass., Dec. 31, 1788. In 1800 he entered the army as a cadet at Newport, R. I., and in 1803 became the first graduate of the military academy at West Point. He was then made 2d lieutenant in the U. S. corps of military engineers, and in 1807, having attained the rank of captain of engineers, he was appointed to the command of West Point. In 1812 he had reached the rank of lieutenant-colonel, and was made aide-de-camp to Major-

Gen. Pinckney in the Carolinas, and the same year succeeded Col. Jonathan Williams in the command of the U. S. corps of engineers, with the rank of colonel. For meritorious services in the campaigns of 1818 and 1814 on the St. Lawrence river, and in defence of the city and harbor of New York, he was brevetted as brigadier-general, and honored by special marks of distinction from the city authorities. After the war he was for several years successively director, superintendent, and inspector of the military academy, still holding his commission as chief engineer of the army until 1818, when, with a number of other officers of the corps, he left the service on the appointment by the president of a distinguished French officer, Gen. Bernard, to the charge of investigating and modifying the coast defences. Gen. Swift was afterward surveyor of the port of New York for 9 years, then civil engineer of the Baltimore and Susquehanna railroad, and from 1829 to 1845, under appointment from President Jackson, superintendent of the harbor improvements on the lakes, removing to Geneva, N. Y., where he has since resided. In the winter of 1880-'31 he constructed the railroad from New Orleans to Lake Pontchartrain, through what was considered an unfathomable swamp, susceptible of neither draining nor piling. This, it is believed, was the first railroad in the United States provided with an iron T rail. It was constructed of massive frames of cypress logs obtained in clearing the way through the swamp, and laid upon a filling of the tertiary fossil shells from the mounds composed of these materials discovered in the swamps. These shells, thus brought into use, were afterward applied, by the advice of Gen. Swift, to the construction of the well known "shell road" to Lake Pontchartrain, and to the completion of the streets in New Orleans. In 1838 Gen. Swift was chief engineer of the Harlem railroad in New York. In 1841 he was sent by President Harrison on an embassy of peace to the governors of Canada, New Brunswick, and Nova Scotia. In 1851 and 1852, with his son McRay Swift, C.E., he made the tour of Europe, and recorded his observations in his diary, a work kept from his boyhood, and in which is a complete history of the military academy at West Point, together with the biography of President Madison and other eminent public men, and essays upon scientific and literary subjects. He has contributed many valuable papers to scientific journals on the exact and natural sciences and their practical applications. Of his sons two have died in the service of their country, one as civil engineer, from exposure; and the other, a distinguished officer of the U. S. engineers, died in Mexico during the war. Another son, Jonathan Williams, an officer in the U. S. naval service, was crippled for life on board the frigate *Brandywine*.

SWIFT, ZEPHANIAH, an American judge, born in Wareham, Mass., in Feb. 1759, died in

Warren, O., Oct. 27, 1833. He was graduated at Yale college in 1778, and established himself in the practice of law at Windham, Conn.; was a member of congress from 1793 to 1796; was secretary of the mission to France in 1800; and in 1801 he was elected a judge, and from 1806 to 1819 was chief justice of the state. In 1814 he was a member of the Hartford convention. He published a "Digest of the Law of Evidence," and a "Treatise on Bills of Exchange" (1810); and a "Digest of the Laws of Connecticut" (2 vols., 1823).

SWIMMING, the art of sustaining the body at the surface of the water, and moving in it, by the aid of the hands or feet, or both acting in unison. Although not a natural faculty of man, there is little difficulty in acquiring the art of swimming, since the human body, except in the case of persons remarkably spare and lean, is specifically lighter than salt water, and hardly perceptibly heavier than fresh water. As to methods, the frog is the best model. The body being inclined at an angle of 45°, the breast downward, the head thrown back, the elbows close to the chest, the arms flexed, the palms downward, and the thumbs brought together near the chin, the knees drawn up but spread apart, and the soles of the feet directed outward and made hollowing by the contraction of the toes, the first movement is the simultaneous one of the hands and feet, the former with the palms still downward describing a horizontal curve of from $\frac{1}{4}$ to $\frac{1}{2}$ of a circle, while the latter are thrown vigorously backward and outward, so that the inner surface of the leg and thigh, as in the case of the frog, shall offer its resistance to the water. Swimming on the back varies very slightly from this in the muscular motions required, though the position of the swimmer is more nearly horizontal, and the hands need not play so important a part; it is possible to swim a long time with the use of the feet only, but not so long with the hands alone, in case of the loss or paralysis of one of the legs. "Treading water," or swimming in a nearly perpendicular position, by a moderate motion of the feet and a slow spreading of the hands, is a method frequently resorted to by good swimmers as a relief from the other modes. In order to float on the back, the swimmer turns himself, and suffers the back of the head to be submerged, the mouth and nose only being above water; the hands are extended, and the legs partially flexed, and spread so as to afford the greatest possible floating surface. In a calm sea, a person may thus lie on the surface for hours, without danger of drowning.—Various plans have been suggested to communicate confidence and self-possession to the learner. Corks, swimming bladders, and life preservers of tin, India rubber, &c., have been used extensively. Dr. Franklin's and Gen. Pfuel's methods are perhaps the best, the one to inspire confidence, and the other to acquire, with a feeling of perfect safety, the muscular movements in their regular order and

sequence. Franklin's directions were, that the learner should take with him an egg or large white pebble, and, wading out till the water was full breast high, face about, and toss the egg or pebble into the water between himself and the shore, yet where it is so deep that he can only reach it by diving, and then plunge after it; in so doing he will find himself buoyed up by the water, and learn, in struggling to reach it, that it is easier for the human body to swim than to sink. By Gen. Pfuel's method a swimming girdle of hemp, about 5 inches wide, was passed loosely around the chest, just under the arms, and to the back of this a ring was attached in which was tied a rope 5 or 6 fathoms in length which could be fastened at will to a pole 8 feet long. The swimming bath or place was to have about 8 feet depth of water, and a rail 4 feet in height above the water protected the platform. From this rail the learner was required to leap, the teacher holding the rope firmly; when in the water, being sustained by the rope, now attached to the pole, the legs and arms stretched out and held firmly together, the chin touching the water, he was directed to assume the position above described at the call of the teacher, "One" being the signal for placing the legs in position, "Two" for the extension of the legs at the widest possible angle, the toes being still contracted and kept outwards, and "Three" for the return to the original position. The learner was exercised in these positions till he could perform them promptly and rapidly, and was then trained in the motions of the hands and arms, and subsequently in the union of the two; he was next allowed to swim, feeling less and less the support of the rope, till it could be cast loose with safety. In most cases a training of one or two lessons daily for 2 or 3 weeks suffices to enable the learner to swim for a half hour without much fatigue, and practice is then only necessary to perfect him.—In leaping or diving the swimmer must keep the muscles firm and the limbs straight and stiff, as to strike the water first with the abdomen, side, or back may be attended with serious consequences. In attempting to save a person from drowning, the swimmer should not allow the drowning person to seize one of his limbs, or to clasp him in his arms, as he will not only be unable to save him, but will himself inevitably be drowned; he should approach him from behind, and if he sinks pull him up by his hair, or raise him by placing the hands under the arm pits; if he is an exhausted swimmer, he may be supported by placing his hand on the shoulder of the swimmer who would save him.—An illustrated treatise on swimming, with full directions for learners, may be found in Walker's "Manly Exercises" (11th ed., London, 1860).

SWINE. See Hog.

SWITZERLAND, a S. E. co. of Indiana, bordering on Kentucky, from which it is separated by the Ohio river; area, 220 sq. m.; pop. in 1860, 12,698. The surface is undulating and

the soil fertile. The productions in 1850 were 401,884 bushels of Indian corn, 78,169 of wheat, 44,455 of oats, and 9,769 tons of hay. There were 8 grist mills, 12 saw mills, 4 tanneries, 27 churches, and 8,541 pupils attending public schools. It was settled by Swiss in 1802. Capital, Vevay.

SWITZERLAND (Lat. *Helvetia*; Ger. *Schweiz*; Fr. *La Suisse*), a federal republic of central Europe, situated between lat. 45° 50' and 47° 50' N., and long. 6° and 10° 25' E. It is bounded N. and E. by Germany, S. by Italy,

and W. by France, and nearly the entire boundary line is formed by rivers (the Rhine and Doubs), lakes (of Constance and Geneva), and mountains (the Alps and Jura). In its greatest length, which is near the parallel of 46° 35' N., it measures 216 m.; in its greatest breadth, a little W. of the meridian of 9° E., 140 m. In 1862 Switzerland consisted of 22 cantons, or, as 8 cantons, Unterwalden, Appenzell, and Basel, are divided into 2 independent half cantons each, of 25 states, the area and population of which are exhibited in the following table:

Cantons.	Area, sq. m.	Pop. in 1850.	Pop. in 1860.	Catholics.	Reformed.	Capitals.
Zürich	659	250,698	267,641	11,497	254,908	Zürich.
Bern	2,015	468,901	488,516	68,572	406,869	Bern.
Lucerne	502	132,843	130,965	128,243	2,697	Lucerne.
Uri	418	14,505	14,761	14,722	39	Altorf.
Schwyz	863	44,163	45,191	44,649	539	Schwyz.
Unterwalden Obwalden	186	12,799	12,899	12,804	95	Sarnen.
Unterwalden Nidwalden	112	11,839	11,561	11,506	55	Stanz.
Glarus	265	30,218	33,459	5,866	27,563	Glarus.
Zug	91	17,461	19,667	19,085	682	Zug.
Freyburg or Fribourg	632	92,891	105,970	90,862	15,578	Freyburg.
Soleure or Solothurn	292	69,674	69,527	69,799	9,626	Soleure.
Basel City	15	29,698	41,251	9,996	30,828	Basel.
Basel Country	166	47,885	51,778	9,824	41,721	Liesthal.
Schaffhausen	118	35,800	35,646	2,080	38,459	Schaffhausen.
Appenzell Outer Rhodes	102	43,691	43,604	2,243	46,329	Herisau and Trogen (alternately).
Appenzell Inner Rhodes	61	11,272	12,020	11,896	133	Appenzell.
St. Gall	781	169,625	181,091	111,067	69,809	St. Gall.
Grisons or Graubünden	2,705	89,895	91,177	29,008	52,166	Chur or Coira.
Aargau or Argovie	589	199,852	194,600	88,668	104,865	Aarau.
Thurgau or Thurgovie	884	98,908	90,847	22,152	67,861	Frauenfeld.
Ticino or Tessin	1,063	117,759	181,896	181,241	118	Lugano.
Vaud	1,226	199,575	218,606	12,981	199,465	Lausanne.
Valais	2,019	81,559	90,880	90,169	697	Sion or Sitten.
Neuchâtel	309	70,758	87,847	9,849	77,416	Neuchâtel.
Geneva	111	64,146	82,845	42,855	40,266	Geneva.
Total	15,747	2,892,740	2,584,240	1,040,469	1,488,296	

The statement of the area of the several cantons rests on the trigonometrical calculations recently made under the direction of Gen. Dufour; but that of the cantons of Bern, Uri, Lucerne, and Unterwalden is based upon an approximative estimate. The population has increased since 1816 about 50 per cent., more slowly than that of the United States and Great Britain, but in a larger ratio than that of France. Geneva, Basel, and Neuchâtel have increased nearly 100 per cent.; Lucerne and Bern more than 50; Zürich nearly 50; while Uri, Appenzell, Unterwalden, and Schaffhausen have remained nearly stationary. Since 1850 Lucerne, Obwalden, Soleure, and Aargau show a small decrease. In 1850 there were 92 towns, 63 hamlets, and 6,800 villages. The population of the towns was 492,600; the largest are Geneva, Bern, Basel, and Zürich. The difference of language still existing points to the difference of origin of the inhabitants of the several cantons. The N., N. E., and central cantons speak a German dialect; the French prevails in the cantons of Vaud, Geneva, and Neuchâtel, and in a part of the cantons of Valais, Freyburg, and Bern; the Italian in the canton of Ticino and in a part of Grisons; and the Romansh, a corrupted dialect of the Latin, which has been supposed to come near the colloquial dialect alleged to have been in use among the Romans, in a part of Grisons. The population speaking these 4 languages is esti-

mated by Kolb (*Handbuch der vergleichenden Statistik*, 1860) as follows: German, 1,750,000; French, 550,000; Italian, 180,000; Romansh, 45,000.—Switzerland is one of the most remarkable countries of the globe for its magnificent and picturesque scenery. It is the most mountainous district of Europe, and, with the Tyrol and Savoy, the most elevated. Even the most level part in the N. presents mountains rising upward of 2,000 feet. It is covered throughout its whole extent by the Alps, of which the 8 following groups, with their various offshoots, belong properly to Switzerland: 1, the Helvetic or Lepontine Alps, which, commencing near Monte Rosa, run through Valais on both sides of the Rhône, by St. Gothard, to the Moschelhorn and the Bernhardino in the Grisons, and separate Switzerland from Lombardy; 2, the Rhetian Alps, which run from the Bernhardino through the whole of the Grisons and the Tyrol, and southward to Monte Pelegrino; 3, the Pennine Alps, which border upon Valais, and separate that canton from Savoy and Piedmont. As to their height the Alps are generally divided into the High Alps, rising from 8,000 to 15,000 feet above the level of the sea, and covered with perpetual snow and ice; the Middle Alps, beginning at about 5,500 feet above the sea, and rising to the line of perpetual congelation; and the Low Alps, commencing with an elevation of about 2,000 feet. The principal Alpine summits are

Monte Rosa in Valais, 15,150 feet; the Mütthorn in Valais, 14,784; the Finsteraarhorn in Bern, 14,106; the peak of the Furca, Mt. St. Gothard, 14,037; the Jungfrau in Bern, 13,718; the Mönchhorn in Bern, 13,498; the Schreckhorn in Bern, 13,886; and the Eiger in Bern, 13,075. Beside these, there are 4 summits ranging from 13,000 to 12,000; 8 from 12,000 to 11,000; 9 from 11,000 to 10,000; and 19 from 10,000 to 6,400. To the west of the Alps, along the boundaries of France, runs a ridge of the Jura mountains lower than the Alps, but presenting many picturesque points of scenery and beautiful valleys. The Jura is united with the Alps by the Jorat, which runs through the canton of Vaud. The glaciers of Switzerland are the reservoirs which feed some of the largest rivers of western Europe. The Rhine and Rhône rise in Switzerland. The former has its 3 sources, the Upper, Middle, and Further Rhine, in the Rhaetian Alps, and pursues in Switzerland or on its E. and N. borders a course of above 200 m. Among its affluents is the Aar, which rises in the S. E. mountains of Bern, receives the Simmen, Saane, Emmen, Reuss, and Limmat, and carries to the Rhine the waters of 14 cantons. The Rhône, which rises in a glacier of the Furca, receives the Visp, Borgne, and Dranse, and after quitting the canton of Geneva becomes a French river. The Ticino flows through the canton to which it has given its name, and passes through Lago Maggiore into Italy; and the Inn waters a part of the canton of Grisons. Switzerland contains a considerable number of lakes, the most important of which are the lake of Geneva, the ancient Lemanus, and those of Constance, Neuchâtel, Bienne, Lucerne, Zürich, Zug, and Sarnen; and S. of the Alps the lake of Lugano and the Lago Maggiore. Most of these lakes are traversed by steamboats.—The more marked geological features of Switzerland have been noticed in the articles ALPS and JURA; and the glacial phenomena of the former mountains, which have been most carefully studied, and which throw so much light upon the dynamics of geology, have been specially treated in the article GLACIER. No country possesses greater interest for geologists than Switzerland, whose formations are exhibited upon the grandest scale, and reveal in the most striking manner the metamorphism to which rocks are subject, converting strata of comparatively recent formation into schistose and crystalline rocks; but its mineral resources are of no great importance. Its iron mines produce from 10,000 to 15,000 tons annually; its lead mines 500 tons; and its copper mines about 250 tons. Anthracite of inferior quality is found in several places, as Outre-Rhône, Salvaut, and Isérable, in Valais, &c. The salt mines near Basel yield about 11,000 tons annually, and those at Bex (Vaud) 2,000 tons. Gypsum is found with the salt. The other mineral products are of little importance, with the exception of the mineral springs, of which there are a large

number, and among them many famous as watering places. The most celebrated are Leuk (Valais), St. Maurice in the valley of Engadin (Grisons), Pfeffers (St. Gall), Baden (Aargau), and Schinznach (Aargau).—To the tourist Switzerland presents a great abundance of natural curiosities. There are many points of view whence the semi-circular array of Alpine peaks, presented at once to the eye, extends for more than 120 m., and comprises between 200 and 300 distinct summits, capped with snow, or bristling with bare rocks. Of the heights commanding such Alpine panoramas the Righi is probably the finest, as it is certainly one of the most accessible; some give preference to the Faulhorn, from its proximity to the great chain, and the High Alps rising close at hand are seen from it to great advantage. For a near view of Alpine scenery, amid the recesses of the mountains, the spots which afford a concentration of the grandest and most sublime objects are the valleys of the Bernese Oberland, those which descend from the Monte Rosa, especially the valleys of Zermatt in Valais and Macugnaga in Piedmont, and those around the base of Mont Blanc, including Chamouni in Savoy. In these districts, the glaciers, the most characteristic feature of the country, are seen to the greatest advantage. Switzerland has numerous waterfalls. The fall of the Rhine deserves the first rank from the volume of water; but it is rather a cataract than a cascade, as it wants height. Other celebrated falls are: the fall of the Aar, at Handeck, Bern; the Stambach or Dust fall, in the Bernese Oberland; the Giesbach, on the lake of Brienz; the fall of the Salenche, near Martigny, Valais, sometimes called Pissevache; Reichenbach falls near Meyringen; the fall of Pianazzo on the Splügen, Grisons; and the Tourtemagne fall, near the Simplon road, in Valais. The principal and most interesting of the Swiss Alpine passes are the Simplon, the St. Gothard, the Splügen, and the Bernardin, both as regards their scenery and the magnificent and skilfully constructed carriage roads which have been made over them. Of passes not traversed by carriage roads, the most striking in point of scenery are those of the Monte Moro and Cervin under Monte Rosa, between the Valais and Piedmont; the Tête Noire and Col de Balme, leading to Chamouni; the Grimsel, Furca, and Gries, branching off at the head of the valley of the Rhône; the Gemmi, between Bern and Valais, one of the most singular of the passes; and the Great St. Bernard, chiefly visited on account of its celebrated hospice. Of the Alpine defiles no other approaches the ravine of the Via Mala, on the Upper Rhine in Grisons, one of the most sublime and terrific scenes anywhere among the Alps. The gorge of the Schöllenen on the St. Gothard, that of Gondo on the Simplon, and that extraordinary glen in whose depths the baths of Pfeffers are sunk, also deserve mention. The *Ranz des Vaches* (Ger. *Kuhreihen*) are a class of melodies pre-

vailing among and peculiar to the Alpine valleys. Almost every valley has an air of its own, but the original air is said to be that of Appenzell.—The climate is more severe than might be expected from the geographical position of Switzerland. On the highest summits snow and ice are perpetual. In the lower mountains and on the table land snow falls in greater abundance than in other countries of the same latitude in Europe. In Valais the fig and grape ripen at the foot of ice-clad mountains, while near their summits the rhododendron and the lichen grow at the limit of the snow line. The canton of Ticino has the climate of Italy, yet the weather is more changeable. Switzerland is on the whole a very healthy country, with the exception of a few places in swampy or very narrow and deep valleys. In the middle ages the country of the Jura suffered much from earthquakes, which have entirely ceased for several centuries; but floods, avalanches, and snow storms still threaten the inhabitants with frequent dangers. About two thirds of the surface consists of lakes and other waters, glaciers, naked rocks, and other uninhabitable heights. Some districts are very fruitful, yet the grain raised is not sufficient for the supply of the population. The vine is cultivated on the slopes of the Jura and in the valleys of the Rhine, Rhône, Reuss, Limmat, and Thur (an affluent of the Rhine), and in some places ripens at 2,100 feet above the sea. Flax and hemp are extensively grown. Irrigation is judiciously managed, and in general agriculture is making progress. The forests cover about 17 per cent. of the soil, and although their cultivation is yet imperfect, the production of timber exceeds the home consumption. Fishing still yields considerable produce, but hunting is no longer practised to the same extent as formerly; the chamois has become rare, and the ibex is no more found. Switzerland is celebrated for its rich and excellent pastures; the finest breeds of cattle are those of the Simmenthal (Bern), Gessenay, Gruyère (Freyburg), Zug, and Schwytz. There are about 900,000 horned cattle, about one fourth of which are milch cows, 105,000 horses, 469,000 sheep, 847,000 goats, and 818,000 swine. The sheep and swine do not supply the home demand. The best cheese is made in the Emmenthal, Saanenthal, and Simmenthal, in Gruyère and Urseren (Uri), and in the valleys of the Emmen, Saane, and Simmen.—Eastern Switzerland has been for more than 150 years the seat of flourishing manufactories. To a smaller degree manufacturing industry prospers in the W. and N. cantons. The chief seats of the cotton manufacture are Appenzell and St. Gall; silks are woven in Zürich and Basel, and linens at Bern. Of great importance is the manufacture of watches in the W. cantons, and they constitute an important article of export.—The commerce of Switzerland stands in fair proportion to its well developed industry. The value of the foreign trade in 1855

was set down at \$90,000,000, and of the domestic trade at \$185,000,000. It increased rapidly until 1855, since which it has decreased somewhat, though not probably below the value in 1855. Most of the duties being specific, it is easier to state the quantity of the articles imported or exported than their values. The rapid increase of the quantity of breadstuffs and coal imported into Switzerland gives ample proof of the development of its industry and the prosperity of its population. In 1855 there were imported only 480,605 cwt. of coal, but in 1860 no less than 2,270,975 cwt. Of breadstuffs (grain, flour, rice) the importation increased from 2,842,191 cwt. in 1850 to 3,717,770 cwt. in 1860; of potatoes, from 81,870 cwt. in 1858 to 877,825 cwt. in 1860. The following statement shows the quantities of the principal articles of import and export during the years 1859 and 1860:

IMPORTS.			
Articles.	1859.—Cwt.	1860.—Cwt.	
Breadstuffs.....	2,706,070	3,717,770	
Potatoes.....	104,940	877,825

The total revenue from customs in 1859 was \$1,480,821, and in 1860 \$1,553,185, of which sum the current expenses of the customs department take 11 per cent., and \$500,000 is distributed among the different cantons to indemnify them for their former customs revenues, leaving about \$800,000 to the federal treasury.—The aggregate length of all chartered railroad lines, Jan. 1, 1860, was 358 leagues. Of these there were in operation 197 leagues, in course of construction 62, not yet commenced 99. The most important lines are: united Swiss railroad, 66 leagues; central railroad, 54; north-east, 37; western, 37; eastern and western, 36; Italian, 33; Lukmanier, 26; Freyburg and Lausanne, 17 leagues. The aggregate length

of electric telegraph, Jan. 1, 1861, was 601 leagues, the number of stations 145, and the total number of telegrams, not including those passing through Swiss territory from foreign countries, was 259,849 in 1859 and 276,963 in 1860. The revenue was \$117,723 in the former year, and \$97,657 in the latter; the expenditure \$100,998 in 1859, and \$87,971 in 1860.—Switzerland has 8 universities, at Basel, Bern, and Zürich, the 2 latter of which were founded in the present century after German models. There are also 2 academies, at Geneva and Lausanne, at which theology, law, and philosophy are taught; and 8 lycæums, at Sion, Einsiedeln, Schaffhausen, Lugano, Chur, Lucerne, Freyburg, and Soleure, each having faculties of theology and philosophy, and some also of law. All the universities and academies are Protestant, and all the lycæums except that at Schaffhausen are Roman Catholic institutions. There are gymnasia and cantonal schools in nearly every canton. The new federal constitution of 1848 provided for the establishment of a federal university (the 8 above mentioned being cantonal institutions), and a committee appointed for drafting a plan submitted its report in 1851 to the federal diet; but the conflicting claims of several cantons as to the location of the university, and of the Reformed and Roman Catholic churches as to its organization, have hitherto prevented the execution of the plan. A federal polytechnic school was, however, founded in 1854 at Zürich, and soon attained a high degree of prosperity and celebrity. The number of public schools amounts to about 5,500, educating upward of 850,000 pupils. The expenses of public instruction are partly paid by the communities (about 4,500,000 francs), partly by special school funds, and partly by appropriations of the cantonal governments (about 900,000 francs). Many private educational institutions have gained a world-wide celebrity since the days of Pestalozzi and Fellenberg, who conducted establishments of this kind at Yverdon (Vaud) and Hofwyl (Bern). A majority of the inhabitants are Protestants, but the Roman Catholics are most numerous in 11 cantons and one half canton, viz.: Lucerne, Uri, Schwytz, Unterwalden, Zug, Freyburg, Valais, Soleure, Ticino, St. Gall, and Geneva, and Appenzell Inner Rhodes. They have 5 bishops, viz.: of Basel (residing at Soleure), Chur, St. Gall, Lausanne (residing in Freyburg), and Sion. The whole of the canton of Ticino and a few congregations in Grisons were formerly under the jurisdiction of the archbishop of Milan and the bishop of Como in Lombardy; but the government of Ticino as well as the federal government have protested against the continuance of this relation, and demanded of the pope the establishment of a new Swiss bishopric in that canton. The Jesuits and Redemptorists are by an express provision of the federal constitution excluded from Switzerland, and the number of the convents of other religious orders has been somewhat

reduced during the present century, yet it still amounts to over 100. The Protestants belong mostly to the Reformed church, which is considered the state church in all the cantons except Lucerne, Uri, Schwytz, Unterwalden, Zug, Freyburg, Soleure, Valais, and Ticino, which have but an insignificant Protestant population. Since 1857 deputies of the Reformed cantonal churches meet annually in a Helvetic conference. Faculties of Protestant theology are connected with the universities of Bern, Zürich, and Basel, and there are also several theological schools in French Switzerland. Basel is the seat of the greatest missionary and Bible society of continental Europe, while the religious societies of French Switzerland have their centre in Geneva. Free churches (Presbyterian or Independent) have been formed during the present century by secession from the state churches, and are especially numerous in the cantons of Geneva and Vaud, in each of which they have also a theological school. The Methodists and Baptists have congregations in several cantons, and the former also a book concern at Zürich. In 1860 the number of Jews, who live mostly in a few communities of the canton of Aargau, was about 300. The number of periodicals published in Switzerland at the close of 1860 was precisely 300, of which 9 were published daily, 28 6 times a week, 20 8 times a week, 56 semi-weekly, 117 weekly, 21 twice a month, and the remainder monthly. The total number was increased in 1861 to 318, of which 210 were in German, 78 in French, 9 in Italian, and 3 in Romansh. The proportion of periodicals to the population is 1 to 7,976, while in France it is only 1 to 26,400. In 7 years, from 1853 to 1860, the aggregate number of copies of periodicals issued in Switzerland increased from 9,484,000 to 16,600,000.—The present federal constitution of Switzerland, which superseded the federal contract of Aug. 7, 1815, and changed the federal union of states into a federal republic, was promulgated Sept. 12, 1848. It provides that all the rights of sovereignty which are not expressly transferred to the confederacy are exercised by the 25 cantons and half cantons. Among the prerogatives of the federal government are the rights of declaring war, of concluding peace or treaties, and of sending diplomatic representatives. The formation of separate alliances between the cantons, without special permission, is prohibited. The constitution of every canton is guaranteed, if it is republican in form, if it has been adopted by the people, and if it can be revised on the demand of a majority of the citizens. All Swiss are equal before the law, and the former relation of subjects as well as all privileges of place or birth are abolished. All Swiss who are Christians have the right of settling in any canton, and of acquiring full civil rights. All recognized Christian denominations enjoy liberty of religious worship. Liberty of the press, of petition, and of association is guaranteed; but the Jesuits and all religious orders and associations

which are affiliated to them are prohibited. The confederacy has the right of sending away dangerous foreigners. The legislative power is vested in the federal assembly, which consists of a national council (*Nationalrath*) and a council of states (*Ständerath*). The national council consists of deputies of the people, in the ratio of about 1 for every 20,000 persons, so that every canton and every independent half canton possesses the right of electing at least 1 councillor. The electoral law of Dec. 1850, divided Switzerland into 48 electoral districts, which elect 120 delegates. The national council is elected for the term of 8 years, and every citizen who is 20 years of age has the right of voting and is eligible. Naturalized citizens may be elected after having been citizens for 5 years. The national council elects for every regular and every extraordinary session a president and vice-president, the former of whom is not eligible during the next following regular session. The council of states has 44 members, 2 for every canton and 1 for every half canton. The members of the national council are paid out of the federal treasury, those of the council of states by the cantons. The executive power is exercised by a federal council, consisting of 7 members, who are chosen for a term of 8 years by the federal assembly (the national council and the council of states in joint session). They divide among themselves the 7 departments of foreign affairs, of the post and edifices, of justice and police, of finance, of war, of the interior, and of commerce and duties, each member taking one department and being at the same time the substitute in a second department. The president and vice-president of the council are chosen for one year only. The federal court, which is also chosen by the federal assembly for a term of 8 years, consists of 11 members. Bern is the federal capital. The 3 national languages are German, French, and Italian. The constitution may at any time undergo a revision in the regular way of legislation; if the two councils disagree, or if 50,000 citizens demand it, the question of a revision has to be submitted to a direct vote of the people. The revised constitution, in order to become effective, must be adopted by a majority of all citizens of Switzerland as well as by a majority of the cantons. The cantonal constitutions may be divided into two classes: 1. Pure democracies, in which the rights of sovereignty are exercised by a general assembly of all citizens, which meets once a year, mostly in April or May, votes upon laws, fixes the taxes, and elects the cantonal officers. The executive is called *Landrath*, and consists of the cantonal officers and the councillors (*Raths-herren*) elected by the several political communities. This is the constitution of Uri, Appenzell, Unterwalden, and Glarus. 2. Representative democracies, in which the people elect a legislative assembly, called the grand council, which chooses from its own number the executive, called little council. In many can-

tons the people have the right of vetoing every bill passed by the grand council. In most of the cantons the members of the grand council receive no pay. Instead of printed law books, some of the smaller cantons used until recently written traditions; the practice is however now disappearing, and nearly every canton has its printed code of laws. Many old Germanic elements are to be found in Swiss law; the Roman law has had a predominating influence only in a few border cantons. The institution of the jury, which was first tried in Geneva, has since been introduced into Vaud, Bern, Zürich, and several other cantons.—The finances of Switzerland are in a very favorable condition. Only a few cantons have a public debt, and some, as Zürich and Bern, possess a large public property. The taxes are nowhere heavy, and in some cantons there are no direct taxes. The federal debt incurred by the war of the Sonderbund has already been liquidated. The budget for 1860 was as follows:

RECEIPTS.		Fr.	Cts.

—The military establishment of Switzerland is based upon purely democratic principles. Every able-bodied citizen is a defender of the republic, not on paper merely or by a legal and constitutional fiction, but actually. The federal army consists of citizens from 20 to 44 years

of age, and is divided into 8 classes according to age. The first class, comprising men from 20 to 34 years of age, constitutes the active field army (*Aussug*); the second class, 34 to 40 years, the reserve army; and the third class, 40 to 44 years, the sedentary militia (*Landwehr*). The federal government provides for the instruction of the engineers, artillery, and cavalry, furnishes part of the material of war to the cantons, and superintends the quality of the material furnished by the cantons. The instruction of infantry soldiers requires 28 days, of riflemen 85 days. All the different classes are required to devote a certain number of days in each year to battalion and brigade drills and field manoeuvres. The Swiss are known to be accurate marksmen with the rifle, and meet constantly to practise and engage in trials of skill. There are clubs and societies in almost every valley and parish, and constant matches between them; beside which a federal rifle match is held every year, at which all the best shots from the whole of Switzerland meet to contend for a prize. Annual contests in wrestling (*Schwingfeste*) also are held in different parts of Switzerland, especially in Bern, Appenzell, and Unterwalden. In Dec. 1860, the field army numbered 81,257 men, the reserve army 43,284, and the militia 61,878; total, 186,419.—The first inhabitants of Switzerland are supposed to have been of Celtic origin, and to have immigrated into the country from the N. E. Their collective name was Helvetians. The high valleys near the sources of the Rhine, in the present canton of Grisons, were occupied by a tribe akin to the Tyrrhenians or Etruscans, called the Rhestians. In 118 B. C. two tribes of Helvetians, the Tigurini and Tugeni (from which are derived the names of Zürich and Zug), joined the Cimbri and Teutons in their inroads into Italy. In this war the Helvetian Divico, in 107, completely routed the Romans under their consul L. Cassius Longinus. After the defeat of the Cimbri in 101, the Helvetians returned unmolested to their mountains, followed, it is believed, by the scattered remnants of the Cimbri, to whom the foundation of the town of Schwytz is ascribed. In the time of Cæsar an entire tribe of the Helvetians, instigated by their leader Orgetorix, determined to conquer seats in Gaul, destroyed their towns and villages, and under the command of Divico crossed the Saône; but they were conquered by Cæsar at Bibracte (Antun), and driven back to their country. Soon afterward the Helvetian tribes were gradually subdued by the Romans, and even the Rhestians, who were the last to maintain their freedom, were compelled at length to yield. For several centuries Switzerland remained a province of the Romans, who introduced their manners, laws, and civilization, and founded several towns, as Augusta Rauracorum (Augst, near Basel), Vindonissa (Windisch, in Aargau), Aventicum (Avenches, in Vaud), and Eburodunum (Yverdon). In the 2d, 3d, and 4th centuries the

country was often harassed by the invasion of German tribes, especially the Alemanni; the Celtic and the Roman elements of the population mostly perished, the towns were sacked, and the country laid waste. In the 6th century the Burgundians, Alemanni, and Goths divided the country among themselves; but the domination exercised by them was of short duration, and they were all in the 6th century brought into subjection by the Franks. Christianity, which had already begun to take root in Burgundian Switzerland, became under the rule of the Franks the religion of the entire country. Many bishoprics and convents were founded, and the bishops and many abbots, as those of St. Gall, Einsiedeln, &c., obtained great political influence. Though wholly incorporated with the empire of the Franks, the country was in point of administration divided into two parts; the one, extending from the lake of Constance and the Rhine to the Aar and St. Gothard, was called Rhestia and Thurgau; and the other, comprising Geneva, Valais, Neuchâtel, Bern, Freyburg, Soleure, &c., was called Little Burgundia. Under the weak reign of Charles the Fat, Switzerland, like many other parts of the empire, was lost to the Franks. The N. part came into the possession of the duke of Alemannia (Swabia), and thus became part of the German empire, while the S. part belonged to Burgundy. During the invasion of Germany by the Hungarians, many towns, as St. Gall, Basel, Zürich, and Lucerne, were fortified, and thus rose in importance. During the reign of the emperors of the house of Saxony the country was mostly held as fiefs by the vassals of the empire, in particular by the bishops and abbots, the counts of Kyburg (Zürich), Hapsburg (Aargau), Lenzburg (Aargau), Rapperswyl (St. Gall), and Toggenburg (St. Gall); later also by the count of Savoy and the duke of Zähringen. Many of these noble families became extinct during the crusades; and the power and prosperity of the towns rose still higher, Bern and Freyburg even becoming free cities of the German empire. Zürich, Bern, and Basel formed an alliance, and tried to make themselves independent. Yet the independence of Switzerland did not proceed from them, but from the three ancient cantons of Schwytz, Uri, and Unterwalden, the inhabitants of which are believed to have descended from immigrants from Sweden, and which had never been conquered. They were only under the protection of the German emperor, near whom their rights were guarded by a *vogt*, first a count of Lenzburg, and afterward a count of Hapsburg. The elevation of Rudolph of Hapsburg to the imperial throne of Germany in 1273, and his conquest of Austria and other possessions of Ottocar of Bohemia, greatly increased the influence of the house of Hapsburg in Switzerland. The son of Rudolph, Albert, sought to incorporate the Swiss with Austria. Bern and Zürich at once resisted successfully; but in the 3 old cantons of Schwytz, Uri, and

Unterwalden he succeeded for a time. The convention entered into by 83 distinguished men of the 3 cantons on the Rütli, a meadow on their common frontier, Nov. 1, 1307, led, on Jan. 1, 1308, to the expulsion of the Austrian officers and the destruction of their castles. The legend of Tell belongs to this period. The relation of the 8 cantons to the German empire remained at first unchanged; but the war of Austria for reestablishing its rule in the emancipated cantons, which lasted with many interruptions for about 200 years, ended with severing also the ties which bound Switzerland to Germany. The Hapsburgs also lost their possessions lying between the Alps and the Rhine, and their old family castles of Hapsburg and Kyburg. The league of the 8 old cantons, which had first been formed in 1291 and renewed in 1308, was again sworn to and established as a perpetual confederacy in 1315, after the great victory over the Austrians at Morgarten on the confines of Schwytz and Zug. In 1332 Lucerne joined the confederacy, which received the name of the Four Forest Cantons. Zürich came in in 1351, Glarus and Zug in 1352, and Bern in 1353, when the 8 united cantons erected the "perpetual league of the 8 old places of the confederacy," so called because no new members were added to the confederacy until 1481, and these 8 old ones enjoyed many privileges until 1798. Other brilliant victories over Austria were gained at Sempach (Lucerne), July 9, 1386, and at Näfels (Glarus), April 9, 1389; after which the Swiss became aggressive in their policy, and at length, notwithstanding their defeats at Arbedo (Ticino) in 1422 and at St. Jacob (Basel) in 1444, annexed a considerable portion of Austrian territory. These protracted wars awakened such a fondness for warfare that many Swiss soldiers, not finding sufficient military occupation at home, entered foreign armies, where, until a very recent period, they earned the questionable reputation of being the most loyal defenders of the cause they had once espoused, even if it were that of despotism. There were sometimes also internal dissensions, and Zürich from 1440 to 1450 seceded from the confederacy. As at this time the canton of Schwytz had a predominant influence in the councils of the confederacy, its cantonal colors (white and red) were adopted as the confederate ensign, and the party name Swiss (Schwytz) became the designation of the entire people. A great war against Charles of Burgundy, the most powerful prince of his times in W. Europe, was gloriously terminated, after brilliant victories had been gained by the Swiss at Granson (Vaud) and Morat (Freyburg) in 1476, and at Nancy in 1477. The admission of Soleure and Freyburg into the confederacy in 1481 almost became the occasion of a civil war, which was however averted by the exhortations of a pious hermit, Nicholas von der Flüe. Other internal dissensions were terminated by a war against the German em-

peror (1498), in which the Swiss showed their usual bravery. The emperor was obliged to conclude in 1499 the peace of Basel, and Basel and Schaffhausen, in recompense for faithful assistance, were admitted as members of the confederacy, to which in 1513 Appenzell was also added. The number of cantons thus rose to 13, and remained so until 1798. The Swiss conquered Lombardy for Duke Maximilian Sforza in 1512, and routed the French at Novara in 1513, but in 1515 lost the great battle at Marignano; nevertheless they found France willing to conclude with them an advantageous peace in 1516, which was kept until 1798. The reformation of the 16th century rent the country into two hostile camps. Among its leaders were Zwingli in Zürich, Eccolampadius in Basel, Haller and Mannel in Bern, Farel and Calvin in Geneva. In most of the cantons the reformation was introduced, but Lucerne, Uri, Schwytz, Unterwalden, and Zug formed a league for the defence of the old faith. Several wars ensued, in one of which Zwingli lost his life (1531) in the battle of Cappel (Zürich), in which the Roman Catholics were victorious. Soon afterward peace was concluded, and every canton left at liberty to introduce or to oppose the reformation. Geneva freed itself, with the aid of Bern, from Savoy, and became in 1536 a Protestant republic, without however being admitted into the confederacy. Vaud was also conquered by Bern from Savoy in 1558 and reformed; but on the other hand, the Catholic cantons of Lucerne, Uri, Schwytz, Unterwalden, Soleure, and Freyburg formed in 1586, by the advice of Archbishop Charles Borromeo of Milan, the "golden league" for the common defence of the Catholic religion. The religious split long continued a prolific source of dissension between the cantons. In 1597 the canton of Appenzell, in order to prevent a religious war, was separated into two independent half cantons, the Catholic part being called Inner Rhodes, and the Reformed Outer Rhodes. In 1602 the Reformed were expelled from Valais, and in 1620 Protestantism was forcibly suppressed in Valtellina. In Grisons a bloody civil war was kindled, in which other cantons also took part, and which made the country one of the chief seats of the war between France, Spain, and Austria. As the federal courts of Germany still continued to make claims on Switzerland as belonging to the German empire, the Swiss sent the burgo-master Weltstein of Basel as their representative to the peace congress of Münster, which at the peace of Westphalia (1648) pronounced Switzerland entirely independent of Germany. From this time until the outbreak of the French revolution in 1789, the history of Switzerland presents few events of general importance. It had no foreign war, and the religious contests at home, which still occurred from time to time, were mostly of short duration. The most important of them was the second war of Toggenburg in 1712, when 150,000 Swiss were

in arms against each other. Other internal commotions arose out of the oligarchic form of government which was gradually established in the cantons of Bern, Freyburg, Soleure, and Lucerne, and out of the oppressed condition of the subjected territories whose inhabitants were excluded from all political rights. In 1798 two French armies marched, without any respectable pretext, into Swiss territory, captured on March 5 the city of Bern, plundered its armory and treasury, and on April 12, 1798, proclaimed at Aarau the one and indivisible Helvetic republic, divided into 18 cantons, with Aarau as the federal capital. By the new constitution Bern was divided into 4 cantons, the subjected districts of Baden, Thurgau, Lugano, and Bellinzona (Ticino) erected into cantons, Zug, Uri, Schwytz, and Unterwalden united into the one canton of the Forest Towns, and Appenzell, St. Gall, and the valley of the Rhine formed into the canton of Sontis. Geneva, Bienne (Bern), and several other portions of Swiss territory were incorporated with the French republic. The resistance of the old forest cantons proved useless, and the new constitution was gradually introduced, though but little liked. Overthrown on the entrance and advance of the allied armies under the command of Suwaroff, it was reestablished after the victories of the French under Masséna. The withdrawal of the French troops in 1802 led at once to revolutions in almost every canton, and a general diet, consisting of an equal number of deputies from the formerly governing and the governed districts, was convoked at Schwytz; but again France interfered, 12,000 French troops subdued the old cantons, and deputies from all the cantons were ordered by Bonaparte to assemble at Paris for the purpose of reorganizing Switzerland. On Feb. 19, 1803, Bonaparte transmitted to them the act of mediation, by which the former cantonal system was restored, although the relation of subjected territories remained abolished. To the 13 old cantons 6 new ones were added, viz.: St. Gall and Grisons, which had formerly been allied with the confederacy without being members, and Aargau, Thurgau, Ticino, and Vaud, which had been subjected territories. At the head of the confederacy was again placed a diet (*Tagsatzung*), consisting of commissioners, voting according to instructions. It was to assemble in turn in the cities of Bern, Zürich, Lucerne, Basel, Freyburg, and Soleure, and the burgo-master of the *Vorort* or temporary capital, under the name of *Landammann* of Switzerland, was to preside at the diet and to attend to all the current affairs of the year. In the democratic cantons the sovereign popular assemblies were reestablished; in the others grand and little councils, the former being elected by a direct vote of the people, and the latter by the grand council. This new constitution was on the whole well received, and under it Switzerland for 10 years enjoyed peace at home and abroad. After the

battle of Leipsic the troops of the allied powers marched through Switzerland. Bern and others of the aristocratic cantons severed their connection with the Helvetic government instituted by the act of mediation, and civil broils ensued in a number of cantons. Yet the attempt to restore the former order of things had soon to be given up, and a new constitution, adopted by the federal diet on May 27, 1815, sworn to at Zürich on Aug. 7, and ratified by the great powers of Europe on Dec. 20, acknowledged all the 19 cantons constituted by the act of mediation, and added 3 new ones, Geneva, Valais, and the Prussian principality of Neuchâtel. The territory of Switzerland was enlarged by portions of land ceded by France (the Dappes valley), Savoy (Carouge and several villages on the lake of Geneva and on the Rhône), and Austria (Razuns, the Frickthal, Laufenburg, and Rheinfelden). The cantons of Soleure, Grisons, Schwytz, and Appenzell Inner Rhodes adopted the constitution only with reluctance, and Nidwalden (one half of Unterwalden) had to be coerced into submission by force of arms. According to the new confederation the cantons guaranteed to each other their constitution, and united for the common defence of their independence. The diet was to assemble annually on June 1, alternately at Bern, Lucerne, and Zürich, and to it was reserved the right of declaring war, concluding peace, and forming alliances with foreign powers. The cantons retained, however, the right of forming with foreign states special military agreements. The existence of the convents and cathedral chapters was guaranteed by a special article. The administration of federal affairs, during the time that the diet was not in session, was left to the *Vorort*. In 1817 Switzerland, upon the invitation of the emperor Alexander of Russia, joined the holy alliance, and from 1828 to 1828 it conceded to the urgent requests of the great powers of Europe a restriction of the liberty of the press and of the right of asylum. The aristocracy recovered in most cantons part of their former prerogatives, and several capital towns greatly enlarged their influence at the expense of the country people. The French revolution of July, 1830, led therefore to violent political agitations in Switzerland. In several cantons the country people rose against the capital towns, and forced them to reorganize the cantonal constitutions on a more liberal and democratic basis. In the canton of Basel a permanent division into two independent half cantons, Basel City and Basel Country, was effected in 1832. In Nov. 1832, some of the most conservative cantons, Uri, Schwytz, Unterwalden, Neuchâtel, and Basel City, formed the "league of Sarnen," and threatened to send no more commissioners to the federal diet if the commissioner from Basel Country were admitted. The federal diet interfered with promptness and energy; the separate league was declared dissolved, and the refractory cantons had to

submit to the federal authority. Altogether, liberal cantonal reforms were introduced in about two thirds of Switzerland. Encouraged by this success, the progressive party conceived also the plan of revising the federal constitution, which seemed to be inadequate to satisfy the want of a closer political union. The diet, on July 17, 1832, pronounced in favor of the revision; yet, when the amendments adopted by the diet were subjected to a direct popular vote, they were voted down by a coalition of the Catholic and the radical parties. The large number of political refugees, who gathered in Switzerland in consequence of the revolutionary movements of 1830, involved the country in serious difficulties with the great powers, which complained of the liberty granted to them by the federal diet. The latter endeavored to conciliate the powers by several resolutions restricting the liberty of the refugees (in 1834 and 1838), and even by the expulsion of some of the leading men among them (1836); yet the diplomatic collisions continued. The demand of the French government, in 1838, for the expulsion of Louis Napoleon, who had been since 1832 a citizen of the canton of Thurgau, was declined by Switzerland, and almost led to a war, which was only avoided by his voluntary departure. An occasion for new religious contests was given by the conference at Baden in 1834, at which delegates of the canton of Bern, Basel Country, Aargau, Thurgau, Lucerne, Soleure, and St. Gall (the first 4 of which are predominantly Protestant), undertook to regulate the relations of the Roman Catholic church in a manner which was rejected by the pope and the bishop of Basel as contrary to the rights and the spirit of the church. The articles of the conference provoked several insurrections, especially in the canton of Aargau, the government of which, in order to punish the revolted Catholic districts, decreed in 1841 the abolition of all the convents. Against this measure most of the Catholic cantons and the ambassador of Austria protested, as a direct violation of that article of the constitution of 1815 which guaranteed the continuance of convents and chapters. Upon the representations of the federal diet Aargau offered to restore 3 female convents, a concession which did not satisfy Austria and the Catholic cantons, but the federal diet by 12½ votes dismissed the subject from its docket (Aug. 31, 1843). A cause of still greater trouble was a motion, made by Aargau at the diet of 1844, for the expulsion of the Jesuits from Switzerland. It was laid on the table by the diet; but when the Catholic *Vorort* Lucerne resolved (Oct. 24, 1844) to call the Jesuits to a cantonal institution, a great excitement spread throughout Switzerland. Two volunteer expeditions (Dec. 1844, and March, 1845) were undertaken for the purpose of overthrowing the government of Lucerne, but both were unsuccessful. On the other hand, the governments of Vaud, Bern, and Zürich, which had voted against the expulsion, had to give way to

others which were in favor of the project. As thus the danger threatening the existence of the schools of the Jesuits increased, the cantons which either had called Jesuits to cantonal institutions, or which patronized them (viz., Lucerne, Uri, Schwytz, Unterwalden, Zug, Freyburg, and Valais), strengthened a separate alliance (the "Sonderbund"), which had already been formed in 1843, and appointed a council of war for the emergency of a civil contest. A motion of Zürich at the diet of 1845 to declare the Sonderbund dissolved received only 10½ votes, but a change of government of Geneva and St. Gall secured for the motion a majority of 12½ votes on July 20, 1846. One Protestant canton (Neuchâtel), one Protestant half canton (Basel City), and one Catholic half canton (Appenzell Inner Rhodes) voted with the cantons of the Sonderbund. In September another resolution declared the expulsion of the Jesuits from all Switzerland. The diet collected an army of nearly 100,000 men under the command of Gen. Dufour, and on Nov. 4 resolved to execute the decree of July 20 by force of arms. The Sonderbund had raised a force of 36,000, which was to be supported by a *Landsturm* of 47,000 men. The war, contrary to expectation, was of short duration. The isolated Freyburg was first attacked, and surrendered after an insignificant skirmish. On Nov. 23 the army of the Sonderbund was routed at Gislicon, near the frontier of the canton of Lucerne; the council of war, the government of Lucerne, and the Jesuits fled, and all the 7 cantons submitted. Austria, France, and Prussia had openly declared during the war their sympathy with the Sonderbund, and in 1848 issued a joint note to Switzerland, demanding that the cantons of the Sonderbund be evacuated, and no change be made in the constitution of 1815, except by the consent of all the cantons. But the revolutions of 1848 drew off the attention of the great powers from Switzerland, and gave the latter an opportunity to hasten a thorough reformation of the federal constitution. The committee of revision commenced its labors on Feb. 17, 1848, and on June 27 the draft of the constitution which is at present in force was submitted to a direct vote of the people. A majority of the cantons and a large majority of the total population voting in favor of it, it was promulgated Sept. 12. In the same year the canton of Neuchâtel declared itself independent of Prussia, which entered against this act an inefficient protest. The success of the counter revolution in 1849 again brought thousands of political refugees to Switzerland, and again, owing to the demands of the great powers, they were made the subject of restrictive and unfavorable legislation, which soon reduced their number to a few hundreds. The expulsion of some Capuchin monks, who were natives of Lombardy, from the canton of Ticino, and the participation of some Italian refugees who had been living in Switzerland in a revolutionary attempt at Mi-

lan in 1858, led to a suspension of diplomatic intercourse with Austria; but the matter was peaceably settled on March 18, 1855. On Sept. 2 the royalists of the canton of Neuchâtel made an attempt to overthrow the government of the canton and to reestablish the sovereignty of the king of Prussia. The movement was at once suppressed (Sept. 3), but led to serious complications with Prussia, which demanded the unconditional pardon of the captured royalists. The demand was supported more or less by all the great powers of Europe; and when the federal council refused to accede to it, Prussia broke off diplomatic relations, and made some warlike demonstrations. When, however, France and England promised their intercession with Prussia in behalf of a recognition of the independence of Neuchâtel, in case Switzerland would release the royalist prisoners, their advice was followed by the federal council. Prussia was now found willing to enter into negotiations, and on April 14, 1857, at a conference of the great powers at Paris, resigned for ever its claims to Neuchâtel. In 1860 Switzerland protested against the annexation of Savoy to France, as a violation of the treaties of 1564 and 1816, by which the neutrality of the districts of Chablais and Faucigny had been guaranteed. It demanded from France the cession of these two districts, but as it was little aided by the great powers, its representations were of no effect.—The principal works on the geography and history of Switzerland are: Sulz, *Topographisches Lexikon der Schweiz* (8 vols., Aarau, 1827); Francini, *Noue Statistique der Schweiz* (2 vols., Bern, 1849; appendix, 1851); Johannes von Müller, *Geschichte der Eidgenossenschaft*, with continuations by Glutz-Blotzheim, Hottinger, Vullemin, and Monnard (18 vols., Leipzig, 1806-'51); Zschokke, *Geschichte des Schweizerlandes* (Zürich, 1822); and Meyer von Knonau, *Handbuch der Geschichte der Schweizerischen Eidgenossenschaft* (2 vols., Zürich, 1828-'9).

SWORD, a weapon used in hand encounters, commonly made like a large knife, and sometimes pointed like a dagger. The ancient Egyptians possessed the art of imparting to bronze extraordinary hardness and elasticity, and employed this material for swords and daggers. Wilkinson describes the former as straight and short, from 2½ to 3 feet in length, having generally a double edge and tapering to a sharp point. Four ancient bronze swords are preserved in the British museum, one of which, supposed to be Etruscan, is about 18 inches long, and is bound round the handle with gold wire. The blades of the others are from 10 to 25 inches long, 1½ to 2 inches wide, and are adapted for cutting and thrusting. The allusions to swords are very frequent in the poems of Homer. The Greeks had several names for the several varieties, and they are spoken of as having silver handles and being studded with silver. They too were of bronze, but at a later period of iron; and as seen upon coins, vases,

&c., they appear to be short cut-and-thrust blades, tapering from hilt to point and provided with a scabbard, which was attached on the left side to a belt suspended from the shoulder or round the waist. The Romans in the time of Polybius had sword blades of finely tempered steel prepared by the Celtiberians. They were short and straight, made for cutting and thrusting, and were worn on the right side. Those of the gladiators were curved. The most famous swords were the Damascus blades of the middle ages, described in the histories of the crusades, and by Scott in the "Talisman." The steel was probably the East Indian wootz, and the manufactured articles were fabricated on the shores of the Mediterranean. (See DAMASCUS BLADES.) Next to these the swords of Toledo in Spain attained great celebrity in the time of the Moors. Though attempts were made to remove the manufacture to Seville, the same processes that were employed at Toledo here failed to produce the same sort of steel; and for want of a better explanation of the cause of the failure, it was attributed to some peculiar excellence in the waters of the Tagus in which those of the Gaudalquivir were lacking. Milan also was famous for its excellent swords during the middle ages. The introduction of gunpowder rendered swords of secondary importance. In the 17th century those made by the Germans were in good repute, and about the year 1689 unsuccessful efforts were made to establish the manufacture with the aid of German workmen in Cumberland, England, and the adjacent counties. It was not, however, until 1786 that good blades were made in that country. At that time Mr. Gill, of Birmingham, competing with German and English makers for supplying the East India company, produced a large number which bore the required test of bending till the length of the blade was reduced from 36 to 29½ inches; and it is stated that they were so keen, tough, and elastic, that Mr. Gill would cut a gun barrel asunder with them, and then wind the blade round it like a ribbon, after which the blade would spring back, and recover its original straightness except at the point. Swords are still made at Toledo of as good quality as ever, but the manufacture employs only 70 or 80 hands.—The best of cast steel is required for good swords. The bars are hammered down by two men striking alternately; and if the blade is to have concave sides or other peculiarities of shape, these are obtained from the dies in which it is swaged. When shaped, it is hardened by heating in the fire to dull red and dipping point downward in a tub of cold water. It is tempered by drawing it through the fire until it acquires a blue color, and is then set or straightened by springing it with the tongs in any required direction as it is held in a sort of fork standing in the anvil. After this it is ground upon a stone with a face adapted to that of the sword, flat or otherwise; is slightly heated to restore the temper impair-

ed by grinding; and is finally polished with emery and crocus.—The small sword used in fencing is a slender weapon for the thrust only, and is the court dress sword. The broad sword, called sometimes the back sword, has but one edge. The heavy two-handed sword, of great length and breadth, made by the Spaniards, is called an *espada*. A sword cane is a hollow walking stick, containing a concealed dagger attached to its handle. A sword bayonet is a sword blade fitted like a bayonet to the musket.

SWORD FISH, the very appropriate name of the *ziphiids*, a family of marine spiny-rayed fishes, allied to the mackerels, so called from the prolongation of the snout into a long, horizontally flattened, sword-like weapon. The sword consists of the vomer and intermaxillary bones, supported at the base by the frontals, nasal, and upper jaw. In form this fish resembles the mackerel; the scales are very small; the jaws proper, and sometimes the sword, are crowded with small, acute teeth, often hardly perceptible; the laminae of each branchial arch are united into a band-like organ, with only superficial marks of separation, as in no other bony fishes; branchiostegal rays in the typical genus *ziphius* (Linn.) 7. The spinous dorsal begins near the head, high and sickle-shaped, extending nearly to the tail, and followed by a small soft fin; the anal is similar but much shorter; ventrals wanting, or represented only by a pair of spinous rays on the throat; caudal deeply forked, on the sides having 1 or 2 large cutaneous folds; the pyloric appendages are collected into bundles and connected by areolar tissue, the branches forming 3 trunks inserted into the intestine close to the pylorus; the stomach caecal and conical, and the air bladder large; the lower jaw in the young is proportionally longer than in the adult; the sclerotic forms a bony box, with a circular opening in front for the cornea, rendering the eyes very movable in their orbits. They are very swift swimmers, and feed on mackerel and other fishes collecting in shoals. The common sword fish (*X. gladius*, Linn.) attains a length of 12 to 20 feet, and is found in the Mediterranean and on both sides of the Atlantic; it is strong and active, using its sword to destroy its enemies, and sometimes striking at vessels, burying its weapon deep in their timbers; in these cases Cuvier thinks it is irritated by parasitic crustaceans which bury themselves in its flesh; or perhaps it mistakes the passing object for a whale, to which it seems to have a special enmity. There are no ventral fins, and the sword is about $\frac{2}{3}$ as long as the body. It occurs on the North American coast from Nova Scotia to New York, being common in the summer in Vineyard sound and between No Man's Land and Block island; it is silvery white below, and tinged above with blackish blue, the sword dark brown above and lighter below. It is fond of pursuing the shoals of mackerel, and may be detected by the dorsal fin projecting above the

water. On the American coast, and also in the Mediterranean, the chase of the sword fish resembles whaling in miniature, and is very exciting; a man aloft gives notice of a fish being near, when the fishermen row toward it, and strike it with a harpoon made for the purpose; by attaching a floating cask to each harpoon, several fish may be struck in a few hours, and each individual separately taken in by following the cask; there is sometimes danger of a small boat being upset or pulled under water by a large fish, which may struggle to escape for hours, and now and then boats are pierced and their occupants severely wounded by the sword of the infuriated animal; some fishermen prefer to take them singly, harpooning them from the bows of a large vessel, and hauling them in at once. The flesh is esteemed as food, both fresh and salted, and in some summers forms a considerable article of commerce with the Vineyard fishermen.—Several species of other genera are found in tropical seas.

SYBARIS, an ancient Greek city of Lucania, in S. Italy, situated on the W. shore of the Tarentine gulf, between the rivers Crathis (now Crati) and Sybaris (Coscile), a short distance from the sea. It was founded by an Achæan colony about 720 B. C. Settlers of other nations were freely admitted to all the rights of citizenship, and a vast population was thus acquired; and through the fertility of the country in which it was situated, the city rose rapidly to great wealth and power. At the time of its greatest prosperity, about 200 years after its foundation, it is stated by Strabo that the city itself occupied a space of 50 stadia in circumference, ruled over 25 subject cities, and could send into the field an army of 800,000 men. It founded Posidonia, Laos, and Scidrus, and carried on an extensive trade, especially with Miletus in Asia Minor. Sybaris was famous throughout the ancient world for the effeminate habits and love of luxury of its citizens. The arts which contributed to the luxurious enjoyment of life were there most highly prized, and it is stated by Athenæus that no craft was permitted in the city which made a noise that might disturb the citizens. The government was entirely in the hands of the aristocracy until about 500 B. C., when Telys, an aristocrat, headed a democratic party, drove out the wealthier citizens and rulers, and raised himself to the position of tyrant. Five hundred of the exiled nobles took refuge at Crotona, and Telys sent thither to demand their surrender. This was refused, and a war ensued in which a large army of Sybarites was beaten by one third the number of the Crotoniats, who followed up their victory by the sack of Sybaris, and turned the course of the river Crathis so that the city was inundated and buried in the deposits that the river brought down. Sybaris was never restored; its site is now a malarious marsh, and its exact position cannot be determined. Its surviving inhabitants, after remaining for many years at Laos and Scidrus

founded near it, with Athenian colonists, the city of Thurii.

SYCAMORE, a name usually applied in the United States to the *platanus occidentalis* (Mx.) or buttonwood tree (see **PLANE TREE**), and in Europe to a species of maple (*acer pseudoplatanus*, Linn.), of which there are several distinct and beautiful varieties known. (See **MAPLE**.) The sycamore of the Sacred Scriptures is a species of fig (*ficus sycamorus*, Linn.), a native of Egypt, where it becomes a considerable timber tree. Its branches spread out widely, affording a grateful shade, and the trees are therefore planted by the sea shore and by the road sides. As it becomes old much of its picturesque beauty vanishes, and its branches are crooked, broken, and leafless. The figs, which are sweet and delicate, are produced in clustered racemes on the trunks and limbs instead of the new shoots. Its timber has been reputed almost indestructible, but Forskahl says it is only fit for fuel.

SYDENHAM, FLORES, an English scholar and translator, born in 1710, died April 1, 1787, in prison, where he had been confined for a debt due the eating house where he dined. He was educated at Wadham college, Oxford. He translated the greater part of Plato's works, which were published between 1759 and 1780 in 3 vols. 4to. The translation in general is excellent, though in a few of the more abstruse passages he failed to express fully the tenets of his author. It was completed in 1804 by Thomas Taylor. He published also "A Dissertation on the Doctrine of Heraclitus" (1775), and *Onomasticon Theologicum* (1784). His sufferings from poverty in his old age, and his miserable death in prison, led to the foundation of the literary fund, which bestows small gratuities on poor and deserving authors.

SYDENHAM, THOMAS, an English physician, born at Windford Eagle, Dorsetshire, in 1624, died in London, Dec. 29, 1689. He was educated at Magdalen hall, Oxford, and in 1648 obtained a fellowship in All Souls' college, and remained there some years pursuing his studies, visiting France in the mean while and attending the lectures of Barbeyrac. About 1660 he went to Westminster, and soon obtained a large practice and great reputation. Abandoning the routine system then in vogue, he based his practice on principles which have exerted a great influence on the profession from that time to this; these principles are, that nature cures diseases; that there is in the human system a recuperative power, which he named the *vis medicatrix nature*, and that this should be aided, not thwarted; and that the symptoms of disease are the language of a suffering and endangered organism, for which the physician should prescribe. He was the first physician who treated small pox with cooling remedies, or intermittent fever with cinchona. His letters and tracts on particular diseases are valuable for the accuracy of their observation. The preparation known as Sydenham's lauda-

num was one of many valuable additions which he made to the materia medica. His largest work, *Observationes Medice circa Morborum Acutorum Historiam et Curationem* (London, 1675), was translated 8 times into English and passed through 25 editions in 100 years. It is still regarded as a valuable work.—In 1843 a society, composed mainly of members of the medical profession, was founded in London under the name of the Sydenham society, having for its object the republication of the works of Sydenham and of other eminent physicians of former times, otherwise inaccessible to professional readers in general.

SYDNEY, a town upon the S. E. coast of Australia, capital of the colony of New South Wales, and residence of the governor-general of Australia. It is situated on the S. side of the estuary or extensive harbor of Port Jackson, about 7 m. W. S. W. from the sea, in lat. 33° 59' S., long. 151° 14' E.; pop., including the suburbs, about 120,000. Part of the town stands upon a promontory, with Darling harbor on the W.; part of it occupies a narrow valley to the E. of this; and the remainder is built upon undulating ground extending S. and still further E., with extensive water frontage to the N. and N. E. Since the discovery of gold in Australia Sydney has advanced very rapidly, and the suburbs of Woolloomooloo, Paddington and Surrey Hills, Redfern and Chippendale, Camperdown, Newtown, and the Glebe are now almost connected with Sydney proper by continuous lines of well built houses; while Balmain and the North Shore have numerous steam ferries, and Pyrmont has lately been joined to the city by a bridge across Darling harbor. The town, whether viewed from the harbor or the adjoining heights, has a very imposing appearance; and the surrounding shores and innumerable bays and rocky promontories of Port Jackson present scenery not to be surpassed in any part of the world. Sydney stands upon a sandstone formation, and this material has been extensively used both in public and private buildings. The streets are generally well laid out, intersecting each other at right angles, and 84 of them have carriage ways not less than 86 feet, and foot ways not less than 12 feet wide. The city is well supplied with water, and the streets lighted with gas. Sydney contains numerous churches, and is the residence of a bishop of the church of England and a Roman Catholic archbishop. It has a university, established in 1850, the degrees of which confer the same rank as those of similar institutions in England. The merchants' exchange, custom house, court house, museum, legislative and executive council chambers, public library, public markets, benevolent asylum, and hospitals are all worthy of notice. The government house is a very handsome structure, beautifully situated among well wooded grounds overlooking the harbor. There are societies for the promotion of the fine arts, floral, horticultural, and agricultural

societies, a botanical garden, several parks, and a domain. A branch of the royal mint was established here in 1855, the coin of which is a legal tender in all the Australian colonies, Mauritius, Ceylon, and Hong Kong.—The harbor is completely landlocked, and vessels of the largest size can come close to the wharfs, which extend along its shores. In 1858 the shipping inward amounted to 848,984 tons, and outward to 866,825 tons. The value of the imports for the same year was £6,058,866, and of the exports £4,186,277. This apparent excess of imports over exports is caused by the exportation of gold coin, of which no account can be taken at the custom house, and also by the large numbers of cattle, horses, and sheep driven across the frontier to Victoria. The chief exports consist of wool, gold, tallow, hides, gums, &c. The corporation revenues for 1858 amounted to £55,451, and the expenditures to £66,862. Considerable efforts have been made of late years to fortify Port Jackson; several batteries occupy commanding positions, and when the projected defences are completed it will be a place of great strength.

SYDNEY, or SIDNEY, a seaport town of Nova Scotia, capital of the county and island of Cape Breton, in lat. 46° 7' N., long. 60° 9' W., about 200 m. N. E. from Halifax; pop. about 1,000. It is well situated at the head of a safe and commodious harbor, with a good light-house at the S. side of its entrance. The importance of the place is principally derived from the extensive coal fields that exist in the neighborhood. The thickness of the bed worked at the Sydney mines is 6 feet, and another at a few miles distance has a seam of 9 feet. The coal from the Sydney mine is conveyed to the wharf by railroad, and during the year ending Sept. 1857, 92,270 tons were exported.

SYENE. See ASSWAN.

SYENITE. See GRANITE.

SYLLA, or SULLA, LUCIUS CORNELIUS (FELIX), a Roman statesman and soldier, born in 138 B. C., died in 78. His family, the original name of which was Rufinus, belonged to the great *Cornelia gens*, one of the noblest of the patrician *gentes*, of the Sabine branch of the early Romans, called Titianses; but his inheritance was small, and in his youth he lived in a house which was in part occupied by a freedman. He however was a diligent student of the literature of his own country, and of that of Greece; and he early indulged that taste for profligate pleasures which characterized his whole life. One of his mistresses bequeathed to him all her property, and to this was added the property of his stepmother, who made him her heir; and thus he became, though not rich according to the Roman estimate of wealth in those days, possessed of means to enter on the career of ambition. He was elected *quaestor* for the year 107, and was appointed to take over to Africa the cavalry sent to Marius. As the new officer's reputation was for profligacy only, the consul was displeased with the ap-

pointment; but Sylla's conduct soon won the confidence of his chief and the regards of the soldiers, with whom he lived on the most familiar terms. Sylla, says Sallust, "when he came into Africa and to the camp of Marius with his cavalry, though he had been before unskilled and ignorant in the art of war, became in a short time the ablest of all. Beside, he used to accost the men with much urbanity, and granted favors to many at their own request, to others of his own accord, but was very unwilling himself to receive any, but those he did he repaid with much more haste than a debt, while he himself never demanded any return from others, but rather was desirous that as many as possible should be his debtors. He would joke or be serious with the humblest, and was very often seen in the encampments, in the march, and amid the watches; nor did he in the mean time, as is the custom of bad ambition, lessen the character of the consul or any worthy man. He only would not suffer any one to be before him in counsel or action, and excelled most. By which behavior and practice he became very dear to Marius and the soldiers." His part in the battle of Cirta, in which Jugurtha and Bocchus were defeated, was a prominent one; and when Bocchus betrayed Jugurtha to the Romans, Sylla was the principal actor on the side of the latter in the negotiations. In the wars that were waged against the Cimbri and Teutones, Marius being consul, Sylla had command as one of his legates, and then as military tribune, distinguishing himself in both stations. The good understanding which had so long existed between them came to an end, however, and Sylla served under Q. Catulus, the other consul, to the increase of his reputation and of the enmity of Marius. For some years Sylla remained a private citizen, but sought the *praetorship* in 94, without success. The next year he was chosen to that post; and in 92 he was sent as *propraetor* to Cilicia, with directions to restore Ariobarzanes to the throne of Cappadocia, from which he had been driven by the king of Pontus. This duty he discharged, and with success so brilliant that the king of the Parthians sent ambassadors to him, asking an alliance with the Romans. This was the first official intercourse between Rome and the Parthians. On his return to Rome, Sylla became the head of the aristocratic party, as his enemy Marius was the chief man among the leaders of the other faction; and both aspired to the command against Mithridates. The breaking out of the social war postponed that appeal to arms which both were anxious to make. In that contest Sylla was much more successful than Marius, winning several victories, capturing towns, and reducing the Samnites, as well as others of the enemies of the Roman supremacy. He allowed great license to the soldiers, and attached them to his person. He was chosen consul for the year 88, and the senate assigned to him command of the army in the East; but Marius placed him-

self at the head of the Italian party, and Sylla was driven from Rome. Hastening to the army that was besieging Nola, he easily prevailed upon it to obey his commands, and marched to Rome, of which he took possession, the Marians being unable to resist him. After restoring the former state of things, he led his army to Greece, of which the troops of Mithridates had taken possession. He besieged Athens, which was stormed March 1, 86, and plundered it. Piræus then fell into his hands; and he followed the enemy into Boeotia, inflicting a crushing defeat upon them at Ocheronea. A new army sent by Mithridates was defeated at Orchomenus. Sylla then crossed the Hellespont, and in 84 he granted peace to the Pontine monarch. He also defeated the Roman general Fimbria, who commanded the army sent by the Marians to the East. Having extorted large sums of money from the Asiatic cities, and leaving two legions in Asia, he led the rest of his army back to Greece to prepare for the war in Italy, where the Marian party had regained ascendancy. He landed at Brundisium in the spring of 83. The senate sought to reconcile the chiefs of the two parties, but a treaty was impossible. Marius was dead, and Cinna, the ablest of his lieutenants, was murdered by his own soldiers; so that, though the Marians had an enormous force in the field, and were supported by the Italians, or new citizens, they had no military chief who could act against the conqueror of Mithridates. Sylla conciliated the Italians, making treaties with many of their towns, and promising to maintain them in the possession of their privileges. Partly by victories in the field and partly by intrigues, he dispersed or gained over both the consular armies that were opposed to him. He was now joined by several influential Romans, among whom were Crassus, Metellus Pius, and the youthful Pompey, the latter bringing with him 3 legions. In 82 Sylla defeated the younger Marius, who was one of the consuls for that year, and shut him up in Præneste. He then proceeded to Rome, and came very near meeting with total defeat at its gates; for Pontius Telesinus, the chief man among the Samnites, with whom the Lucanians were united, resolved to march direct upon the city, in order, as he said, to destroy the wolves of Italy in their den. The Samnite hate of the Romans had survived two centuries of subjugation, and Telesinus sought to accomplish that which his ancestors had failed to effect before the Roman arms had achieved any thing out of Italy. The Samnites had not received the new franchise, and they were animated by the most vindictive feeling toward the Romans. Failing to effect the relief of Præneste, which was besieged by Ofella, Telesinus proceeded to Rome, which was defenceless, and reached the city but a short time before Sylla also arrived at its gates. The battle that followed was one of the greatest ever fought. Sylla commanded the left wing of his army, which was routed and driven from the

field; but the right wing, under Crassus, was victorious, and retrieved the battle. The number of men who fell on both sides was 100,000. The Samnites and Lucanians who were captured were all put to death, and Præneste surrendered, young Marius having committed suicide on seeing the head of Telesinus. In a short time the greater part of the Roman world submitted to the victor, the only man who continued to resist his rule being Sertorius, who carried on the war in Spain until his own death, and for several years after the death of Sylla. The aristocratical leader took the severest vengeance on his enemies, and Italy was the scene of a reign of terror. He introduced the proscriptions, which were lists of his enemies that were exhibited in the forum, and all persons were authorized to kill any one whose name could there be found. To gratify his adherents, he placed in these lists the names of their enemies, or those of persons whose property they desired to seize. He caused himself to be appointed dictator, thus reviving an office that had been unknown to the Romans for 120 years; but while he was dictator he was elected consul. No one of the Caesars was ever more powerful than was Sylla during his dictatorship, supported as he was by an enormous army, by a large number of slaves whom he had enfranchised (they had belonged to persons who had figured in the proscriptions), by the military colonies he had established throughout Italy, and by the influence which had been created by his successes, his energy, and his cruelty. During his dictatorship a large number of laws were adopted tending to concentrate the power of the state in the aristocracy. He took from the assemblies of the tribes their legislative and judicial power, and also the right to elect priests. No matter was allowed to be brought before the centuries without the previous sanction of a *senatus consultum*. He filled up the senate, and placed the government of the provinces entirely in its hands; and renewed the old laws with regard to magistrates, requiring a regular gradation from office to office, and that no one should be reelected to the same office till after the expiration of 10 years. The number of quaestors was increased from 8 to 20; of prætors from 6 to 8. He reduced the power of the plebeian tribunes to a mere shadow of what it had been, and forbade all tribunes from aspiring to the higher curule offices. The right of self-election was restored to the ecclesiastical corporations, and the number of pontiffs, augurs, and keepers of the sibylline books was increased to 15 respectively. The aristocracy regained the privilege of having judges taken exclusively from the senatorian order, of which they had been deprived by Caius Gracchus. He reformed the criminal law, enacted sumptuary laws, and sought to regulate marriages. Few of his measures long survived him. "Sylla's enactments," says Mr. G. Long, "were not, like the imperial constitutions of a later day, the mere act of one who held

the sovereign power; they were laws (*leges*) duly passed by the popular assembly. Yet they were Sylla's work, and the legislative body merely gave them formal sanction. The object of Sylla's constitutional measures was to give an aristocratical character to the Roman constitution, to restore it to something of its pristine state, and to weaken the popular party by curtailing the power of the tribunes." As soon as he had completed his legislation, Sylla resigned his dictatorship (79 B. C.), and gave to the people an account of his conduct as a public officer. He had none of that ambition which afterward led Cæsar to found the imperial power; but it may be doubted if he could have performed the part that Cæsar played, had he been inclined to take it. He valued the pleasures of sense and of letters as much as he did those of power, and, feeling secure in the strength of the system he had set up, he devoted the remainder of his days to personal indulgence, residing at Puteoli. He suffered from the horrible disease known as the *morbus pedicularis*; but it has been said that this is one of the calumnies of his enemies, that his illness was only a fever, and that his death was immediately occasioned by the bursting of a blood vessel. At the time of his triumph, in 81, he took the surname of Felix, because he attributed his success to the gods; and when he had to do with Greeks, he called himself Epaphroditus. Venus he claimed as his especial patroness, who had given him success both in love and in war. He was 5 times married, and his last wife, Valeria, gave birth to a daughter after his death. He wrote memoirs, in 22 books, the last of which was completed but two days before his death, and with his full knowledge that his end was near. He dictated his own epitaph, which says, in substance, that "none of his friends ever did him a kindness, and none of his enemies ever did him a wrong, without being fully repaid." "Sylla," says Mr. Long, "was an educated man; he was not a mere soldier like Marius. He was not only a general; he was a man of letters, a lover of the arts, a keen discriminator of men and times, a legislator, and a statesman. He remodelled and reformed the whole criminal law of the Romans. His constitutional measures were not permanent, but it may truly be said that he prepared the way for the temporary usurpation of Cæsar, and the permanent establishment of the Roman state under Augustus."

SYLVA, BUENO DA. See BUENO DA SYLVA.

SYMBOLS, CHEMICAL, abbreviations for expressing the chemical composition of bodies. The idea of representing the names of chemical substances by conventional signs or abbreviations appears to be a very old one. The alchemists were in possession of a set of hieroglyphics by which the metals, and the four so called elements, fire, air, earth, and water, and indeed many other substances, were designated. At a later period, as chemical knowledge

became more consolidated, various modifications of the alchemical notation were from time to time proposed, and adopted to a greater or less extent. Among these should be specially mentioned the system of notation offered in 1787 by Hassenfratz and Adet, as an appendix to Guyton de Morveau's revised system of nomenclature, since its failure enables us the better to appreciate the peculiar excellence of the system which now prevails. Here was a system of symbols by no means devoid of ingenuity, and much more complete than any previous method, published in connection with a new system of nomenclature, which was soon universally adopted, and recommended by the committee of the French academy by whom this nomenclature had been prepared; yet it met with little or no favor among chemists, and was soon forgotten. This last remark applies as well to the symbols proposed by Dalton in 1808, in connection with his writings upon the atomic theory. None of these systems ever came into general use, nor does it appear that they were of much value as instruments of study even in the special cases in which they were employed. It is to Berzelius that chemical science is indebted for the simple and rational system of notation now in use, which has done so much, especially of late years, to advance knowledge and to lighten the labors of chemical investigators. This system, in its first outlines at least, appears not to have been the result of any premeditated plan or special study, but to have followed incidentally as a natural result from the investigation of the combining proportions of bodies with which its author was occupied. Thus in 1814 he first mentions his symbols in a foot note to a memoir upon nitrous acid (Gilbert's *Annalen der Physik*, xlv. 154), as convenient abbreviations for expressing the composition of bodies, which he has himself frequently employed in his private memoranda. Subsequently a more complete exposition of the plan appeared in his *Lehrbuch*, and in Poggendorff's *Annalen*, 1826, viii. 7. As a sign to express the name and combining equivalent of an element, Berzelius chose the initial letter of its Latin name; and in those cases where the names of several elements commence with the same letter, he annexed to the common initial the first of the following letters in the Latin name of the element which is peculiar to it; thus, the symbol O indicates an equivalent of carbon, Cl an equivalent of chlorine, and Cr an equivalent of chromium. (For a complete list of these symbols, see EQUIVALENT, CHEMICAL.) The symbols of binary compounds are formed by placing together the symbols of their components, CoO for example representing an equivalent of oxide of cobalt, from Co (cobalt) and O (oxygen); those of ternaries (salts) by uniting the symbols of their component binaries, a comma being placed between these, as OdO, SO₃, sulphate of cadmium; and those of quaternaries (double salts) on the

same principle, a semicolon or the sign + being placed between the binaries of which they are formed, as CdO, SO_2 ; MgO, SO_2 ; + 6HO , hydrated sulphate of cadmium and magnesia; the sign + is commonly used to indicate a component which is less essential to the existence of the compound than the other ingredients, it being possible in the cited case to remove the water without destroying the compound CdO, SO_2 ; MgO, SO_2 . This supposed subordinate part of the water of crystallization of salts is often denoted by putting the symbol Aq (*aqua*) in place of HO . When it is desired to represent more than one equivalent of a substance, figures in large type may be placed before, *i. e.*, to the left of it, or in small type to the right or after it, just below the line upon which the symbol itself is placed. A figure on the left hand multiplies all the symbols to the right of it as far as the first comma, or indeed the whole formula when this is enclosed in brackets, while a small figure to the right multiplies only the letter, or bracketed formula, immediately to the left of it; thus NH_4 (ammonia) denotes an equivalent of a compound containing 1N (nitrogen) and 3H (hydrogen); Fe_2O_3 denotes one equivalent of sesquioxide of iron, and $2\text{Fe}_2\text{O}_3$ two equivalents of the same base.—In constructing formulas, it is also convenient to preserve a definite arrangement of the letters and members. In the spoken names of chemical substances, as oxide of iron, chloride of potassium, &c., we first express the term which denotes the acid or electro-negative component; but in the written symbols the reverse of this is customary, the symbol of the basic or positive element being placed first, *i. e.*, at the left hand, as FeO , KCl , &c. So too with the names of salts, the formula of sulphate of potash being written KO, SO_2 , not SO_2, KO . The reason of this order is that the symbols express not English but Latin words, and the construction of the Latin language requires that the genitive must precede the nominative that governs it.—Formulas are called rational when their several members are grouped so that they shall express either what some have supposed to be the actual arrangement of the components of the body which they represent, or in some conventional manner by which the relation which exists between the composition and properties of the body and its behavior toward other substances may be called to mind; and empirical formulas are those in which only the elements present and the number of equivalents of each are noted, without any definite arrangement being given to the list. Thus, $\text{Fe}_2\text{O}_3, 3\text{SO}_2$ is one way of writing a rational formula of tersulphate of iron, while $\text{Fe}_2\text{S}_3\text{O}_{12}$ is its empirical formula.—The system of collocation of symbols and formulas thus far described, which is that of the so called dualistic school of chemists, and the one of which the public at large has most cognizance, is employed only upon a portion of chemical substances. Although exceedingly convenient in certain cases, and suf-

ficiently complete for most purposes of elementary instruction, it would be quite impracticable to employ it in the study of very complex substances, for which other and various arrangements of the symbols are consequently brought into use. Even for the most common and simple cases chemists have proposed methods of arrangement different from the one just mentioned. Thus Davy in his so called binary theory proposed to write K, SO_2 , instead of KO, SO_2 for sulphate of potash, &c.; and others, objecting entirely to the theory of dualism, have suggested the idea of giving special prominence to the empirical formula of a substance, which in their view expresses all our positive knowledge of its composition, leaving it to every one to theorize upon this as he may please. It is precisely in affording facilities for speculating upon and comparing the composition of compounds, and for presenting one's hypotheses to others, that the immense importance of chemical symbols chiefly lies; and this not only from the direct influence which they exert in leading to new discoveries, but also indirectly in tending to prevent abrupt changes and infinite confusion in the spoken nomenclature, which would otherwise inevitably occur. For example, so long as Davy had the means of expressing his view of the constitution of sulphate of potash by writing the formula K, SO_2 , he had but slight incentive to introduce a new name for this substance. The nomenclature is thus kept within limits, ill defined though they be, which render it far more useful than if it were allowed to vacillate and expand indefinitely. Berzelius's original idea was to employ his symbols and formulas merely as convenient substitutes for the names of substances, and this at an epoch when the name was thought to express even the molecular constitution of a compound, or the actual arrangement of its component atoms—a view which has since been very materially modified. It is now felt to be in many cases not only unnecessary and impossible, but often undesirable, to force the symbolic and the spoken nomenclatures into agreement with each other, however convenient such agreement may be in other instances, or even as the general rule. In many cases, where it would be impossible in practice to express an idea of the rational constitution of a substance by any combination of names, a single glance at its written formula is sufficient to convey this idea; and in others several different rational formulas may with equal propriety be assigned to one and the same substance, in which case the body may indeed also have several names, of which each might be better adapted than any of the others to express its composition in some one special instance; but as a rule, when a spoken name has once come into general use, it is not easy to substitute another for it, although the formula of the body may be changed as often as may be found convenient. In spite of all this, much confusion has no doubt arisen from the

John G. Pava.

1. The first step in the stamping process is the design of the stamp. The stamp is a metal plate with a raised surface that corresponds to the shape of the stamp to be made. The stamp is then used to press the stamp into a material, such as paper or metal, to create the stamp.

2. The second step is the preparation of the stamp. The stamp is made by a process called electroplating. This involves depositing a layer of metal onto a substrate. The substrate is a metal plate with a raised surface that corresponds to the shape of the stamp to be made. The metal is deposited onto the substrate by a process called electroplating. This involves depositing a layer of metal onto a substrate.

3. The third step is the stamping process. The stamp is used to press the stamp into a material, such as paper or metal, to create the stamp. The stamp is then used to press the stamp into a material, such as paper or metal, to create the stamp.

4. The fourth step is the finishing process. The stamp is finished by a process called electroplating. This involves depositing a layer of metal onto a substrate. The substrate is a metal plate with a raised surface that corresponds to the shape of the stamp to be made. The metal is deposited onto the substrate by a process called electroplating. This involves depositing a layer of metal onto a substrate.

5. The fifth step is the distribution process. The stamp is distributed to the customers. The stamp is then used to press the stamp into a material, such as paper or metal, to create the stamp.

6. The sixth step is the maintenance process. The stamp is maintained by a process called electroplating. This involves depositing a layer of metal onto a substrate. The substrate is a metal plate with a raised surface that corresponds to the shape of the stamp to be made. The metal is deposited onto the substrate by a process called electroplating. This involves depositing a layer of metal onto a substrate.

7. The seventh step is the replacement process. The stamp is replaced by a new stamp. The stamp is then used to press the stamp into a material, such as paper or metal, to create the stamp.

8. The eighth step is the disposal process. The stamp is disposed of by a process called electroplating. This involves depositing a layer of metal onto a substrate. The substrate is a metal plate with a raised surface that corresponds to the shape of the stamp to be made. The metal is deposited onto the substrate by a process called electroplating. This involves depositing a layer of metal onto a substrate.

9. The ninth step is the recycling process. The stamp is recycled by a process called electroplating. This involves depositing a layer of metal onto a substrate. The substrate is a metal plate with a raised surface that corresponds to the shape of the stamp to be made. The metal is deposited onto the substrate by a process called electroplating. This involves depositing a layer of metal onto a substrate.

10. The tenth step is the storage process. The stamp is stored by a process called electroplating. This involves depositing a layer of metal onto a substrate. The substrate is a metal plate with a raised surface that corresponds to the shape of the stamp to be made. The metal is deposited onto the substrate by a process called electroplating. This involves depositing a layer of metal onto a substrate.

Handwritten signature or mark, possibly reading "S. L. 1881" or similar, located at the bottom center of the page.

multiplication of spoken names; but when compared with what might have been but for the use of symbols and formulas this is hardly deserving of mention.—Many chemists, claiming that in the existing state of science it is impossible that formulas can be made to express any thing more than the relations and analogies which bodies bear to each other, and that consequently those formulas must be the best which are capable of exhibiting the largest number of these relations and analogies, now make no effort to represent the actual arrangement of the atoms of chemical compounds, but seek only to designate the elements or groups which, in the double decompositions by which compounds are formed or destroyed, replace or are replaced by other elements or groups of elements. In order to do this, it has been found convenient to throw all substances into a few great classes of analogues, the leading member or type of each of these divisions being some familiar and well characterized compound, and to derive the formula of each and every member of a given class from the formula of its own peculiar type or pattern.

Thus water, $\begin{matrix} \text{H} \\ \text{H} \end{matrix} \left\{ \text{O}_2 \right\}$, might be taken as a type to which all other compounds may be referred, but the use of several types has been found more convenient. Gerhardt in his *Traité* refers to 4 types, viz., water, $\begin{matrix} \text{H} \\ \text{H} \end{matrix} \left\{ \text{O}_2 \right\}$; ammonia,

$\text{N} \left\{ \begin{matrix} \text{H} \\ \text{H} \\ \text{H} \end{matrix} \right\}$; hydrogen, $\begin{matrix} \text{H} \\ \text{H} \end{matrix} \left\{ \right\}$; and chlorhydric acid, $\begin{matrix} \text{H} \\ \text{Cl} \end{matrix} \left\{ \right\}$. In many cases, however, a multiple of one or the other of these types is the true typical formula, as $\begin{matrix} \text{H}_2 \\ \text{H}_2 \end{matrix} \left\{ \text{O}_2 \right\}$, $\begin{matrix} \text{H}_2 \\ \text{H}_2 \end{matrix} \left\{ \text{O}_2 \right\}$, &c. Other

chemists, and perhaps these are still the majority, believing that the doctrine of duality contains an element of truth which should not be discarded, seek to preserve this by adhering to the prevailing method of writing formulas, though all admit its imperfections.—Carrying out his original idea of abbreviations at a time when he was chiefly occupied with the study of compounds in mineral chemistry, and notably with those of oxygen and sulphur, Berzelius suggested that it might be convenient in special cases to make use of certain modifications of the symbols already described, where the object is merely to indicate the composition of a complex body without discussing its reactions and decompositions; for instance, the number of equivalents of oxygen in a compound was denoted by dots placed above the radical with which this element was supposed to be combined, and the equivalents of sulphur in like manner by commas or accents; and in cases where two atoms of the radical combine with 1, 3, or 5 atoms of oxygen or the like, this double atom of the radical was characterized by a dash drawn through the lower part of the letter which stands for the radical (as $\text{H} = \text{H}_2$);

thus CuO, SO_2 would be written $\text{Cu}\overset{\cdot}{\text{S}}$, and $\text{Fe}\overset{\cdot}{\text{S}}$, instead of $\text{Fe}_2\text{O}_3, 3\text{SO}_2$; K instead of KS ; KMnO_4 instead of KS, MoS_3 . Of these modifications the dashed symbols alone have been at all generally accepted. The dots and accents have been much employed by mineralogists, but were little esteemed by the generality of chemists. Indeed, it is now customary to use the accent marks to express an entirely different idea, viz., to characterize polyatomic radicals; that is, compounds which, in uniting with or reacting upon other bodies, play the part not of one but of two or more atoms of a simple element, or, in the language of the chemists who refer all formulas to types, those radicals which replace more than one atom of hydrogen in the type water. Thus the normal chloride of ethylene, $\text{C}_2\text{H}_4\text{Cl}_2$, contains not only one but two atoms of chlorine, and cannot therefore be referred directly to the simple type HCl , but to the double of this, H_2Cl_2 ; and to denote that the compound C_2H_4 replaces 2H , i. e., that it is a diatomic radical, it is customary to write it with a double accent, thus, $\text{C}_2\overset{\cdot\cdot}{\text{H}}_4$, and the formula of the compound in question $\text{C}_2\overset{\cdot\cdot}{\text{H}}_4\overset{\cdot}{\text{Cl}}_2$. So, too, the formula of

tartaric acid is written $\text{C}_2\overset{\cdot\cdot}{\text{H}}_4\overset{\cdot\cdot}{\text{O}}_6$, and

that of glycerine $\text{C}_3\overset{\cdot\cdot}{\text{H}}_7\overset{\cdot\cdot}{\text{O}}_3$, which represent them as being derived from 2 and 3 atoms of water respectively by the substitution of the diatomic radical $\text{C}_2\overset{\cdot\cdot}{\text{H}}_4\overset{\cdot}{\text{O}}$ for 2 atoms of hydrogen in the one case, and of the triatomic radical $\text{C}_2\overset{\cdot\cdot}{\text{H}}_4\overset{\cdot\cdot}{\text{O}}$ for 3 atoms of hydrogen in the other. In like manner, hydrated sesquioxide of iron would be written $\text{Fe}_2\overset{\cdot\cdot}{\text{O}}_3$ instead of

$\text{Fe}_2\text{O}_3, 3\text{HO}$; Fe_2 being considered as a triatomic radical; so too quinoine, $\text{N}_2\overset{\cdot\cdot}{\text{C}}_{10}\overset{\cdot\cdot}{\text{H}}_{17}$, in which the 3 atoms of H of the type ammonia are replaced by the triatomic radical $\text{C}_3\overset{\cdot\cdot}{\text{H}}_7$; strychnine, $\text{N}_2\overset{\cdot\cdot}{\text{C}}_{10}\overset{\cdot\cdot}{\text{H}}_{17}\overset{\cdot\cdot}{\text{O}}_7$, i. e., the double type $\text{N}_2\overset{\cdot\cdot}{\text{C}}_{10}\overset{\cdot\cdot}{\text{H}}_{17}$, in which the 6 atoms of H have

all been replaced by the hexatomic radical $\text{C}_6\overset{\cdot\cdot}{\text{H}}_{12}\overset{\cdot\cdot}{\text{O}}_3$.—Another abbreviation which has been proposed for the purpose of designating some organic compounds consists in employing the initial letter of the ordinary name of any of these, with one or more additional smaller letters when the first is not of itself characteristic, with a dash above if the compound is an acid or a + sign when it is an alkaloid; thus $\overset{+}{\text{O}}$ stands for oxalic acid, $\overset{+}{\text{A}}$ for acetic acid, $\overset{+}{\text{Q}}$ for quinine, Cy for cyanogen, &c. These are still sometimes used in special cases, although they have but little to recommend and much to condemn them.—Very many methods of arranging formulas, beside those which have here been alluded to, are employed by different chemists to express their own peculiar theoretical notions of the composition of bodies, but a

discussion of these special instances would here be misplaced. Many of these are sufficiently complex and difficult of comprehension; but in its essential features the system of notation employed by chemists is still the universal language which Berzelius provided in choosing his symbols from the Latin nomenclature.

SYMMACHUS, QUINTUS AURELIUS, a Roman statesman and author, who flourished about the close of the 4th century. He was educated in Gaul, and, after being quæstor and prætor, was appointed in A. D. 865 corrector of Lucania and the Bruttii. In 873 he was proconsul of Africa, in 884 prefect of the city, and in 891 consul. He was a sincere pagan, and labored strenuously to maintain that declining faith. He was possessed of immense wealth, and his leisure hours were devoted to liberal studies. His extant works are 10 books of epistles containing 965 letters, and fragments of orations which Angelo Mai discovered in one of the palimpsests of the Ambrosian library, and others from a Turin and Vatican MS. The first edition of the epistles was published without date or name of place in the pontificate of Julius II. One of the best is that of Scioppius (4to., Mentz, 1608).

SYMMACHUS THE SAMARITAN, a native of Samaria, who flourished about A. D. 300. He was at first of the Samaritan religion, then became a Jew, and then a Christian of the sect of the Ebionites. He made the 4th Greek translation of the Old Testament, which occupied the 4th column of Origen's *Hexapla*, but of which only a few fragments now exist, collected by Montfaucon.

SYMMES, JOHN OLIVES, an American soldier and projector, born in New Jersey about 1780, died at Hamilton, Butler co., Ohio, May 28, 1829. He entered the army as ensign in 1802, and in the war of 1812 fought with great gallantry at Lundy's Lane and the sortie from Fort Erie. Subsequently he settled at Newport, Ky., and devoted himself to researches connected with a favorite theory invented by him, according to which the earth is hollow, open at the poles, and capable of being inhabited within. He wrote and lectured much on this subject, and in 1822 and 1823 petitioned congress for means to fit out an expedition to test the truth of his theories. He made a few converts, but his suggestions were generally treated with open ridicule or silent contempt, the author being considered little better than a lunatic. He died in considerable pecuniary embarrassment, much respected for his integrity.

SYMPATHETIC INK. See **INK**, vol. ix. p. 530.

SYMPHONY (Gr. *συμ*, with, and *φωνη*, voice), a term originally signifying merely a concordance of tones, but applied successively to certain vocal compositions, to compositions partly vocal and partly instrumental, to short introductory or intermediate instrumental passages in compositions which are predominantly vocal, and finally to elaborate and extended composi-

tions in which instruments only are employed. The germ of the modern symphony may be found in the *Concerti grossi* of Corelli, and in the works of Geminiani and Vivaldi, produced in the early part of the 18th century; but previous to the time of Haydn the composition in its present form was unknown. The last named composer divided it into 4 or 5 parts, performed successively, and developing distinct ideas, but having a general relation. In the structure of the symphony the parts are generally made to contrast with each other, a slow or *andante* movement being succeeded by an *allegro* or quick one, and this by an *andante* again or an *adagio*, after which comes a minuet and trio, or a scherzo, the whole concluding with a rapid finale. The chief composers of this form of music are Haydn, Mozart, Beethoven, Spohr, and Mendelssohn, the greatest being Beethoven. The 9th or "Choral Symphony" of this master differs from works of its class in introducing vocal music into the concluding movement.

SYMPLEGADES. See **ARGONAUTS**.

SYNAGOGUE (Gr. *συναγωγη*, assembly, place of assembly; Heb. *beth hakkeneseth*, house of assembly), a building appropriated to worship and the performance of public religious rites in Jewish congregations. Corresponding to the word church in Christian terminology, the term is also applied to the Jewish community in general. The earliest synagogues, established in the times of Persian and Greek rule in Judæa, were destined also for deliberative purposes. (For the "great synagogue" see **HEBREW**, vol. ix. p. 87.) In subsequent centuries they were also used as seats of popular as well as higher instruction. In modern Jewish communities this is imparted in a separate building, called *beth hamidrash*, house of study. The synagogue is generally a high and plain building, facing the 4 cardinal points, and provided with seats and desks on the floor for the male members of the congregation, and with galleries for the females. The east wall, which all must face during the recital of certain prayers, encloses the "holy ark" (*aron hakodesh*), in which Hebrew copies of the Pentateuch, written on vellum, are deposited; and opposite it, near the centre, is the platform (*bimah*) on which the reading from the same is performed by the reciter or cantor (*hasan*), or by a special reader (*ba'al kore*). Sermons or lectures are delivered from a smaller platform adjoining the "holy ark," by the rabbi or a special preacher or lecturer. Frequently, however, the offices of reciter, reader, and lecturer are united in the same person.—Among the most celebrated synagogues in various periods are mentioned those of Alexandria, Bagdad, Toledo, and Prague.

SYNCOPE, a fainting fit or swoon. Syncope may occur from a large, and particularly from a sudden loss of blood; from a sudden impression made on the nervous system, as fright, horror, &c.; from the effect of a variety of poisons

which influence the heart's action; or from in-
anition or debility, which weakens the muscu-
lar power of the heart along with that of the
voluntary muscles. If the heart ceases com-
pletely to beat for any time, the individual dies;
but in an ordinary fainting fit, as it is termed,
the heart continues to beat, though so feebly
and faintly that its beat may not be felt; still
the ear applied directly over it will distinguish
the sound made by its contraction. In such
cases the patient should be placed in a horizon-
tal position, with the head if possible a little
lower than the body. Cold water may be
dashed over the face and chest to excite the
respiratory act. Ammonia may be held to the
nostrils, and stimulants administered if possible
by the mouth, if not by enema.

SYNDIO (Gr. *συνδικος*, from *συν*, with, and
δικη, justice), an administrative officer in vari-
ous cities or other communities, and in cor-
porate bodies. At Athens any person appoint-
ed to represent the state in an affair in dispute
with another state was called syndic. In Latin
authors the word *syndicus* is used in the sense
of attorney. In the middle ages the syndio
represented a university, a church, or any cor-
porate body at law, and transacted its general
business. Syndic was the usual name for the
town clerk in some parts of France. By Frois-
sart the word syndic is used as a hereditary
title of nobility in some cases where it had
been only given originally as the title of an ad-
ministrative officer. The merchants or others
who composed the chambers of commerce es-
tablished in France in 1701 were called *syndics
du commerce*.

SYNESIUS, a Christian bishop, philosopher,
and poet of the 5th century, born in Cyrene,
Africa, probably in 379. The date of his death
is unknown. His family was rich and noble,
and boasted a line of ancestry reaching back to
the Heraclides. He was a pupil at Alexandria
of the celebrated Hypatia, afterward studied at
Athens, and returning to Cyrene lived for a
time in retirement, engaged in study. Famine
having come upon Cyrene, Synesius was sent to
Constantinople to solicit aid, and was successful.
After 3 years' stay in the Byzantine capital, he
returned to Cyrene, and soon afterward, under
the influence of a Christian wife, renounced
paganism. In 410, on the death of the bishop
of Ptolemais (now Tolmeta), Synesius was cho-
sen to the see, although he had not been bap-
tized, was married, and held opinions concern-
ing the preexistence of souls, the eternity of
the world, and the resurrection, which were
not regarded in the church as orthodox. He
accepted the post with reluctance, was baptiz-
ed, and after 7 months of preparation entered
upon his episcopal duties. Some instances are
recorded of his firmness in prohibiting heresies;
but his mind seems to have been more exercised
by troubles in the state than by discords in the
church. His works consist of epistles, treat-
ises, and hymns. The best complete collec-
tion of them is that of Petavins, in Greek with

a Latin translation, editions of which appeared
at Paris in 1612, 1688, and 1640. A new and
more critical edition was published by Krabinger
(2 vols. 8vo., Berlin, 1851). Many editions
of the hymns have been published with trans-
lations into various tongues. A French ver-
sion first appeared in 1581, and new ones in
1836 and 1839.

SYNOD (Gr. *συνδος*, meeting), in the ancient
church, an assembly of bishops, in which con-
troversial points of doctrine or discipline were
decided. In the Roman Catholic church, 4
classes of synods are at present distinguished,
diocesan, provincial, national, and oecumenical,
the last of which is always, and the 2d and 3d
are frequently, called councils. (See COUNCIL.)
In the Greek church all these 4 classes of syn-
ods have fallen into desuetude, but there are
"holy synods," or supreme ecclesiastical boards
of administration, at St. Petersburg, Constanti-
nople, and Athens. In the Episcopal church of
Great Britain, the British colonies, and Amer-
ica, the provincial and diocesan synods are now
either in full use or on the point of restoration;
the church in America has also a general synod.
In the Presbyterian churches the synod is an
essential link in their constitution, and consists
of delegates, clerical and lay, of several pres-
byteries. They also have national synods
called general assemblies. With the Presby-
terian the Lutheran, German Reformed, and
Reformed Dutch churches in America agree,
which are also divided into synods, and at cer-
tain intervals convene a general synod. (In the
German Reformed church the formation of a
general synod has been decided upon, but not
yet effected.) In the churches of continental
Europe, the synodical constitution has for a long
time been either wholly abrogated or greatly
curtailed by the territorial system, which places
the government of the church wholly in the
hands of the state officers, or by the consistorial
system, which divides the administration of the
church between ecclesiastical boards called
consistories and appointed by the secular gov-
ernment, and synods elected by the congrega-
tions. But since the beginning of the 19th
century there has been a general and in-
creasing tendency in the churches to return to
the synodical constitution; territorial divisions
have been almost entirely abandoned, and the
consistories are yielding up many of their func-
tions to the restored synods. Austria and some
of the smaller German states, as Oldenburg and
Baden, have almost purely synodical constitu-
tions; nearly all the other German states have
a regular system of diocesan synods and gen-
eral synods by the side of their consistories.
The same is the case in Switzerland, France,
Belgium, and Holland, in all of which countries
free churches have been formed, which reject
the interference of the states and of state
boards in church affairs, while the state
churches generally demand at least the restora-
tion of the old synodical system by the side of
the consistorial.

SYNONYMES (Gr. *συνωνυμίες*, from *συν*, together with, and *ωνυμια*, a name), words of the same language which are the precise equivalents of each other. As there are perhaps no two words absolutely identical in meaning, the term is ordinarily applied to those which are of similar significance, and which are likely to be confounded from their general resemblance, but require to be distinguished by reason of special differences. The idiosyncrasies of individuals, or the local usage of districts, may give different shades of meaning to words that agree in the main. Speakers and writers, to avoid the unpleasant effect of repetition, are often obliged to introduce a great variety of terms to convey the same thought. Words, not distinguishable in definition, may be employed under different circumstances, many terms being restricted to poetical, religious, or secular purposes. Many words become nearly synonymous by figurative or metaphorical usage, though etymologically of different signification; thus, Snorro's Edda enumerates 150 synonyms for sword. Especially in composite languages synonyms are introduced from different sources, as, in English, trick, device, finesse, artifice, and stratagem, respectively from the Saxon, Italian, French, Latin, and Greek. Such words, though etymologically identical in meaning, are generally distinguished by usage; thus, sphere (Gr.) belongs rather to scientific and poetical, and globe (Lat.) to popular language; shepherd (Anglo-Sax.) retains its primary meaning of keeper of sheep, and pastor (Lat.) has only an ecclesiastical sense; love (Anglo-Sax.) and charity (Gr.) are interchanged in the New Testament, but now charity signifies only one particular manifestation of love; illegible (Lat.) is applied to handwriting, and unreadable (Anglo-Sax.) to subject matter. The same root is often developed into different but kindred words, as human and humane, gentle and genteel, property and propriety, piety and pity, triumph and trump (card), etiquette and ticket, ghostly and ghastly, cant and chant. De Quincey says that "all languages tend to clear themselves of synonyms as intellectual culture advances, the superfluous words being taken up and appropriated by new shades and combinations of thought evolved in the progress of society. And long before this appropriation is fixed and petrified into the acknowledged vocabulary of the language, an insensible *clinamen* prepares the way for it." Precise diverse meanings are fixed upon synonyms, as invention and discovery; and words indicative of insignificant distinctions disappear from the language, as has been the case with a large number of the technical terms of the chase. "Few languages," says Mr. G. P. Marsh, "are richer than English in approximate synonyms and conjugates; and it is much to be regretted that no competent scholar has yet devoted himself to the investigation of this branch of our philology. The little manual edited by Archbishop Whately, containing

scarcely more than 400 words, is, as far as it goes, the most satisfactory treatise we have on the subject. Crabbe's 'Synonymes,' much used in this country, is valuable chiefly for its simplifications; but the author's great ignorance of etymology has led him into many errors; and it cannot pretend to compare with the many excellent works on synonymy of the German, French, Danish, and other European languages."—The oldest extant treatise on synonyms is by Ammonius of Alexandria (about A. D. 389). None of the ancient Latin works on the subject have been preserved. The best modern treatises on Latin synonyms are by Ramshorn, Döderlein, Habicht, Schmalfeld, and Schultz; on German, by Eberhard, Maass, and Weigand; and on French, by Girard, Beauzée, Roubaud, Guizot, and Lafaye (2 vols., 1841-'57).

SYNTHESIS. See **ANALYSIS**.

SYPHAX, a Numidian prince, born about 249 B. C., died in 201. In 218 he was king of the Massasylians, the westernmost tribe of the Numidians, and was at war with Carthage; and through this circumstance he became allied with the two Scipios, who materially contributed to his success against the Carthaginians. But Carthage formed a strong combination against him, and he was at length beaten by Hasdrubal and Masinissa, in a great battle in which 80,000 men are said to have fallen. Syphax fled to Mauritania and collected a new force, but was again defeated by Masinissa. He subsequently regained possession of his throne, apparently by treaty with the Carthaginians. In 206 Scipio once more endeavored to bring him into a Roman alliance; but Hasdrubal gave him in marriage his beautiful daughter Sophonisba, though she had previously been promised to Masinissa, and thus secured his adherence to Carthage. Upon the death of Gala, king of the Massylians, his son Masinissa, after a contest with rival claimants, had ascended the throne; but Syphax with Carthaginian aid wrested it from him and made him a fugitive. When Scipio landed in Africa in 204, Syphax joined the Carthaginians with an army of 50,000 foot and 10,000 horse. In the spring of 203 his camp was suddenly attacked at night by Scipio (with whom he had been long negotiating for peace), the straw huts of the soldiers were fired, and nearly the whole army perished in the conflagration or were put to the sword. Syphax assembled another army, joined Hasdrubal, and was again entirely defeated. His kingdom was now invaded by his old enemy Masinissa with Roman allies. He assembled a third army, met them as they approached his capital, was defeated, fell into the hands of the Romans, and was sent a prisoner to Scipio. By him he was sent to Rome, and upon the conqueror's return, according to Polybius, appeared in his triumphal procession; but according to Livy he died at Tibur a few days before.

SYRA, or **SYROS**, a Grecian island, included in the Cyclades, 20 m. N. W. from Paros; area, 65 sq. m.; pop. about 42,000. The out-

line of the island is very irregular, and the coasts are steep and rugged. The surface is intersected by hills and narrow valleys, and the soil is not very fertile in consequence of a deficient supply of water. The hills are mostly composed of mica slate, and the principal minerals are iron ore and an inferior kind of marble. The climate is cooler than that of the neighboring islands, and is considered particularly healthy. The chief productions are wheat, barley, cotton, wine, figs, and silk.—SYRA, NEW SYROS, or HERMOPOLIS, the capital of the island and of the Greek prefecture of the Cyclades, is situated at the head of a bay on the E. coast, near the site of the ancient city; pop. about 80,000. It contains several churches, a gymnasium, a quarantine establishment, several good private schools, and a custom house. It is the seat of a Roman Catholic bishop, and of the Greek bishop of the Cyclades. The harbor is large and convenient, and is the centre of steam navigation in the archipelago. An active trade exists in silk, manufactured goods, and coffee; and ship building is carried on. During the war of independence, Syra, being under the protection of France, did not take part in the hostilities against Turkey, and it became an entrepot for the commerce of Greece and the neighboring islands.

SYRACUSE, a city and the capital of Onondaga co., N. Y., situated at the head of Onondaga lake on a creek bearing the same name, 148 m. W. by N. from Albany, 80 m. E. by S. from Rochester, and 85 m. S. S. E. from Oswego; pop. in 1850, 22,271; in 1860, 28,199. The greater portion of the city occupies a level tract at the head of the lake, and a ridge from 100 to 200 feet high extends through the eastern part. From its central location it is a favorite point for holding state conventions, and hence is styled the "city of conventions." It has ample streets, and is regularly laid out and substantially built. The value of dwellings in 1855 was \$6,228,627. The state asylum for idiots is the most imposing structure, erected in 1855 at a cost of \$86,000, just S. W. of the city limits, on land given by the people of Syracuse. The grounds embrace 18 acres, commanding a fine view of the entire city. The institution has proved highly successful; its average number of inmates is about 100. The other charitable institutions are the Syracuse home association and the Onondaga county orphan asylum. The court house, built of Onondaga limestone at a cost of \$40,000, is one of the finest edifices of its kind in the state. The state arsenal is a handsome building surrounded by a beautiful parade ground. The city hall and other public buildings are substantial structures. The city has 28 churches, viz.: 2 Baptist, 1 Congregational, 3 Episcopal, 4 Methodist Episcopal, 1 German Methodist, 1 Wesleyan Methodist, 2 Jewish synagogues, 2 Lutheran, 3 Presbyterian, 1 Reformed Dutch, 4 Roman Catholic, 1 Unitarian, and 3 of other denominations. There are 3 daily and 7

weekly newspapers. The city has 18 public schools, with a classical department or high school; and in 1860 the average attendance of pupils was 2,977, and the amount of money expended was \$30,745.05. The district libraries number 5,181 volumes, and there is a central library in the city hall for the use of the schools, containing 4,000 volumes. There are also 2 seminaries, a classical school, a commercial college, and a boarding school for boys. There are 11 banks of issue and deposit, 2 savings banks, and a number of private banking offices. The city is supplied with water by a company. It is on the line of the Erie canal and of the New York central railroad; and the Oswego canal, Oswego and Syracuse railroad, and Syracuse, Binghamton, and New York railroad terminate here. The commerce and travel are unusually large for an interior city.—SYRACUSE is the depot of the greatest salt-producing region in the Union. (See SALT, vol. xiv. p. 805.) The principal manufactures are 8 furnaces, producing articles to the value of \$100,000 annually; 7 machine shops, producing \$813,000, and employing 320 hands; 3 silver ware manufactories, \$47,000; 7 tin and sheet iron factories, \$66,000; 9 breweries, over \$400,000; 2 chandleries and soap factories, \$42,000; 1 gas factory, \$20,294; 1 boat yard, employing 50 hands; 8 gypsum bakeries, \$13,000; 2 sash and blind factories, \$85,785; 6 coach and wagon factories, \$55,950; 1 wheelbarrow factory, \$20,000; 3 grist and flouring mills, \$363,275; 1 box factory, \$30,000; 12 cooper shops, \$49,120; 1 planing mill, \$63,880; 2 saw mills, \$37,500; 2 stone cutting establishments, \$13,500; 1 water lime establishment, \$6,000; 7 boot and shoe factories, \$143,200; 6 saddle and harness shops, \$31,500; 1 saddle and coach hardware manufactory, \$57,120; 1 tannery, \$30,000; 5 cabinet shops, \$117,100; 4 hat and cap factories, \$32,800; 5 tobacco and cigar manufactories, \$150,000; a piano factory, 9 printing offices, and various other manufactories. The machine shops of the central railroad at this place employ about 150 hands, and as many more are engaged as conductors, brakemen, and track hands.—The first settlement was made in 1787. It was a small village until the completion of the Erie canal in 1825, since which it has rapidly increased. In 1847 it was incorporated as a city.

SYRACUSE (anc. *Syracusa*; Ital. *Siracusa* or *Siragosa*), a city of Sicily, on the E. coast, 80 m. S. S. E. from Catania, and 81 m. S. S. W. from Messina; pop. about 16,000. It is fortified, and maintains a garrison, but is commanded by the heights of Achradina. It is the see of a bishop, and has a fine cathedral, 185 feet long and 75 wide, anciently the temple of Minerva; numerous palaces, and several churches, convents, and other public buildings. The streets are narrow, and there are extensive ruins of the amphitheatres, baths, &c., of the ancient city, some of them in good preservation. The city has some trade in wine, oil,

brandy, fruits, salt, saltpetre, sulphur, and a little grain.—The ancient Syracuse was the largest city of Sicily; its walls, flanked by towers, were 22 m. in circuit, and the number of inhabitants in its most prosperous period is stated by different writers at 500,000, 900,000, and even 1,200,000. It really consisted of 5 towns adjoining each other, but separated by walls, viz., Ortygia, Achradina, Tyche, Neapolis, and the Epipolæ, and hence was sometimes called Pentapolis. The original city was Ortygia, built upon an island of an oblong shape about 2 m. in circuit, situated between the Great or Greek harbor on the W. and the Little harbor on the E.; it was after a time connected with the mainland by a causeway, and was then spoken of as Ortygia on the peninsula. Achradina, which was next in age, was situated on the other side of the Little harbor, and extended along the sea coast for about 3 m. E. to the port of Trogilius, which was without the limits of the city; it was built partly on the lowlands along the shore, and partly on the heights which rise in a wall of rocks some little distance inland. North of Achradina and on the same range of heights stood Tyche, separated from it only by a double wall and a highway between; it extended northward about 2 m., and at its W. extremity, commanding Ortygia, were several heights named the Epipolæ, which were enclosed by Dionysius the Elder and formed one vast fortress. S. W. of Tyche, and opposite Ortygia, on the lowlands and extending to the wall of Achradina, at the foot of the heights, was Neapolis or the new town. On the W. of Ortygia, around the shores of the Great harbor as far as to the rocky peninsula of Plemmyrium, were suburbs and gardens occupied by the overflowing population of the city. After the Roman conquest, as the city declined in wealth and population, its limits became more restricted; at the time of Augustus it occupied only Ortygia and the lower part of Achradina, and since its capture by the Saracens it has been confined to the Ortygian peninsula. The heights of Achradina now present only a surface of rock, the ancient buildings and the soil having been alike removed. The sea has undermined the shore, the walls have disappeared, and over the elevated and extensive plain only steps hewn in the rock or a few courses of stone give evidence of the vast population which once inhabited it. On the peninsula and the lowland portion of Achradina and Neapolis, evidences of the former greatness of Syracuse are more abundant. Near the borders of Tyche, Achradina, and Neapolis, is the ancient theatre hewn out of the rock and now much overgrown with bushes; it contained 66 ranges of seats, all cut in the rock, and could accommodate 40,000 spectators. Not far from this are the ruins of an amphitheatre of the Roman period. Nearer to Ortygia are the ruins of the palace of Agathocles, and on the peninsula are traces of several other palaces. The *laetumia* or *latomia*, originally quarries

cut in the wall of rocks which formed the face of the heights of Achradina, and excavated to the depth of 60 to 80 feet, are still perfect. Some of them were used as prisons; in one the Athenian prisoners were confined on the surrender of Nicias, and most of them perished. Near the site of the ancient theatre, on one side of the quarry, is that remarkable prison cut in the rock, now called the "ear of Dionysius." There are also catacombs of great extent containing subterranean streets of tombs, in which Greek and Roman, Christian and Saracen, have all found burial. The remains of a great aqueduct begun by Gelon and improved by Hiero also exist. Near the left bank of the Anapus, outside the walls and S. W. of the city, are the ruins of the temple of Jupiter Olympius. The celebrated fountain of Arethusa, now used, it is said, as a public bath, still exists as a large pool in the peninsula; a wall separates it from the sea. There are also remains of several baths, one of them with a spiral staircase. In the museum of the modern city are preserved statues, vases, coins, and inscriptions gathered from the ruins.—Syracuse was founded by Archias, the son of Euagetus, a Corinthian exile, who with a band of Corinthians and Dorians settled in the island of Ortygia in 734 B. C. Within 70 years from its establishment it had begun to send out colonies, among which were Acraë (664), Casmenæ (about 644), and Camarina (599). In 485 B. C., the Gamori, the ruling oligarchy, having been expelled, Gelon, the despot of Gela, undertook their cause, and not only effected their restoration, but made himself master of the city, to which he removed, and which, by transferring thither the inhabitants of Gela and several other cities, he greatly enlarged, and brought to a high state of prosperity. At his death in 478, Hiero, an able though somewhat despotic monarch, succeeded to the throne, and by his patronage of literature made it the favorite resort of the Greek poets and dramatists of the time, including Æschylus, Pindar, Bacchylides, Epicharmus, and Sophron. His brother Thrasybulus succeeded him in 467, but his tyranny and violence disgusted the Syracusans, and after a reign of a year he was expelled and a popular government instituted. In the autumn of 415 the Athenians, as allies of the Segestans, then at war with Syracuse, landed a hostile force in the Great harbor near its walls, and in the spring of 414 commenced a regular siege of the city; but the citizens, under Gylippus, resisted the besiegers so skilfully that at the end of a year their entire remaining force of 7,000 men, with their commanders Nicias and Democritus, were taken prisoners. (See Gædex, vol. viii. p. 447.) In 410 the Carthaginians commenced their aggressions upon Syracuse, and in 405 Dionysius the Elder, taking advantage of the apparently impending danger, made himself despot of the city, and, concluding a peace with the Carthaginians, ruled vigorously but tyrannically for 38 years. During his reign

the city was so strongly fortified as to become impregnable to the repeated assaults of the Carthaginians. He was succeeded in 867 by his son Dionysius the Younger, whose tyranny and debauchery brought about his expulsion by Dion in 369; he regained his power in 346, but was finally expelled by Timoleon in 343. The restoration of liberty to Syracuse by the latter was followed by unexampled though brief prosperity; and 27 years later Agathocles acquired despotic power over the city, and used it for 28 years to plunge her in new and destructive wars. After his death (289) a short respite was had, but soon new tyrants assumed the sway, till in 270 Hiero II. obtained supreme power, and maintained a firm and judicious administration, greatly to the benefit of Syracuse, for nearly 60 years. In 263 he made a treaty with Rome, whose steadfast ally he thenceforward became. During his reign Syracuse attained to its highest splendor and magnificence. With his death (216), however, a great change took place. His grandson and successor Hieronymus abandoned the alliance of Rome for that of Carthage, and after his death the Carthaginians brought about an open rupture with Rome, which led to the siege of Syracuse by Marcellus (214-213), a siege rendered illustrious by the patriotic efforts of Archimedes for its defence, but which finally resulted in its capture and plunder. It then declined into an ordinary Roman provincial town, its population diminished, and it was only of importance as the capital of Sicily and the seat of a proconsular court. It continued to retrograde in wealth and population, and in 88 B. C. and the succeeding years was so plundered and despoiled by Sextus Pompey that Augustus sent thither a Roman colony to strengthen it. It was probably at this time that the Roman amphitheatre was erected. In the 4th century, though much decayed, it was still one of the largest cities of Sicily. It fell into the hands of the Goths at the overthrow of the western empire, but was recaptured by Belisarius in A. D. 535, and remained a fief of the Byzantine emperors till 878, when, after repeated attacks for 60 years and a siege of 9 months, it fell into the hands of the Saracens, who, exasperated at the obstinacy of its defence, massacred its inhabitants, destroyed its fortifications, and burned the city. From this terrible blow it has never recovered. It was partially rebuilt and fortified by Charles V., but in 1698 and again in 1757 was nearly destroyed by earthquakes.

SYRIA (Arab. *Esh-Sham*, the Aram of the Scriptures), a territory of Asiatic Turkey, bounded N. by Adana and Marash, N. E. by the Euphrates, E. and S. by Al Jezira and Arabia, and W. by the Mediterranean, between lat. 31° and 37° 35' N., and long. 34° and 38° 45' E.; area, 144,433 sq. m.; pop. 2,750,000. It is divided into the pashalics of Aleppo or Haleb, Tripoli or Tarablos, Acre or Akka, Gaza, and Damascus, named from their respective capitals.

The only important indentation on the coast is the large gulf of Iskenderoon or Scanderoon at the extreme N.; there are several small bays, as those of Acre, Tripoli, Beyrout, and Saida. The principal rivers are the Jordan, the Asi or Aasy (the ancient Orontes), the Litany (Leontes), the Kishon, the Yarmuk (Hieromax), the Burada (Abana), and the Awaj (Pharpar). The Euphrates drains the N. E. border. The only lakes of importance are the Dead sea and the lake of Tiberias or Gennesareth. The Taurus range forms a part of the N. boundary, and separates Syria from Asia Minor. The two parallel chains which extend through Syria from N. to S., the Libanus or Lebanon and the Anti-Libanus, are offsets from that range, forming low hills, and rising again to the snow line as they approach the Sinaitic peninsula. The W. or Lebanon chain runs parallel to the coast, and seldom more than 12 m. distant from it, to the plain of Esdraelon below Mt. Tabor; it is broken by the passage of the Orontes and the Leontes. Its highest summit ("at the entering in of Hamath") is more than 10,000 feet above the sea, and on its side are the remnant of the ancient "cedars of Lebanon." Separated from this by a beautiful and fertile valley, from 7 to 20 m. in width, is the Anti-Libanus chain, generally lower, though in its loftiest summit, Mt. Hermon, rivalling the highest peaks of the Lebanon range. East of Hermon, a chain of low mountains stretches E. past Damascus; below it the country is hilly, and, viewed from the deep depression of the Jordan valley, seems mountainous. The mountains of Gilead E. of the Jordan form the culminating point of these hills. Further E., in the Hauran, is a lofty table land, waterless, and with vast black bowlders and rocks scattered over its face. The most remarkable feature of the topography of Syria is the extraordinary depression of the valley of the Jordan. The valley of Cœle-Syria, between the Libanus and the Anti-Libanus, is about 70 m. long, and is elevated about 2,300 feet above the sea; it formerly contained Heliopolis or Baalbec, and other great cities. At its southern termination it divides into two branches, one cutting through the Lebanon range in the narrow gorge through which the Leontes finds its way to the sea, the other striking off southward and descending rapidly for 15 m. to the source of the Jordan at the W. base of Hermon. Passing onward with a steady but rapid slope, at the plain El-Huleh it is at the sea level; at the lake of Tiberias it is 658 feet below it; and within 60 m. of direct distance, though by the circuitous channel of the river nearly 200 m., at the Dead sea, it is 1,312 feet below the Mediterranean. No similar river valley is known. Among the level tracts of Syria, beside Cœle-Syria, may be named the great plain of Esdraelon, that of Sharon, and the arid sandy plain of Gaza. The Hauran is, but for its black basaltic rocks, much like some of the steppes of Higher Asia. Around Damascus, an oasis in the desert, vast

plains of sand extend E. and S., and cover the region where once stood Palmyra.—The geology of Syria is interesting. In the extreme south are only primitive rocks, the variegated granite of the Sinaitic peninsula; the deep chasm of the Dead sea, with its bitumen pits, salt mountains, and warm springs, belongs to the carboniferous era; the calcareous and sandstone formations of Hermon and Lebanon abound in fossils of the era of the new red sandstone; and the porphyry and basalt of the Hauran give evidence of their igneous origin. The soil is exceedingly fertile wherever there are sufficient rains, or irrigation can be practised; but where there is no water, it is sandy and utterly barren. The region around the Dead sea is thoroughly impregnated with salt and alkalies, and is entirely devoid of vegetation. In the S. and E. there are vast sandy wastes. The desert in which the children of Israel wandered does not properly belong to Syria.—There are few countries of the same extent in which the climate is so varied as in Syria. On the slopes of Lebanon it is cool and pleasant in the summer months, and in the winter heavy rains fall, but the cold is not severe. In the valley of the Jordan the summer heat is equal to that of the hottest portion of the tropics, and on the sea coast the summers are also very hot and unhealthy. In winter Beyrout and some of the other cities of the coast are healthy and pleasant as residences for invalids. In Jerusalem the heat is oppressive during the day in summer; rain seldom falls between the end of April and the beginning of October, and there are few clouds, and hence every thing is parched till the rainy season. Damascus is colder in winter than the western slopes of Lebanon, and snow frequently falls; yet the orange and fig thrive there. The average range of heat in the hottest part of summer at Jerusalem and Damascus is from 84° to 86° F.; in winter the two cities differ materially in temperature. In Aleppo the range of the thermometer during the year is very great, falling below zero in winter and rising above 100° in summer.—The mineral productions of Syria are iron of excellent quality, the swords and cutlery of Damascus and the iron implements of S. Syria having for ages maintained the highest reputation; a little quicksilver and some coal in the south; and in the Dead sea region salt and bitumen. Salt of very good quality is also made on the shores of the Mediterranean.—The agriculture of Syria is very rude, the implements and modes of culture being nearly identical with those in use 2,500 years ago. Still, even with this imperfect culture, the crops, wherever there are rains or irrigation can be practised, are large, and the cultivation of the soil would lead to wealth if the government were not so oppressive, and the danger from the incursions and robberies of the roving Bedouins not so great. As it is, the poor *jellah* or farmer plants and reaps his crop by stealth, and only in those

portions which are least exposed to the eye of the robber and tax gatherer. Wheat, barley, durra, and spelt are largely produced, as well as rice, lentils, peas, &c.; cotton, hemp, silk, madder, indigo, sesamum, castor oil, tobacco, potatoes, capsicum, melons, cucumbers, and artichokes are also important crops. Figs, olives, mulberries, grapes, almonds, apricots, peaches, pomegranates, oranges, lemons, dates, and other fruits abound. Vineyards are numerous on the mountain slopes and in the hill country of Judæa; the grapes are large and luscious, and the wine made from them of excellent quality. Storax is produced for the market. In the vicinity of Damascus are extensive fields of roses, the petals of which furnish the attar of commerce. The sycamore, Indian fig, carob, mulberry, and pistachio trees grow abundantly, both wild and cultivated. Scammony and sumach are gathered about Mt. Lebanon for exportation. The cedar, pine, and fir are found in extensive forests on the mountains, though the true cedar of Lebanon, once so highly prized for building purposes, is nearly extinct. The arbutus, terebinth, laurel, and several species of juniper occur on the table lands, where are also found dwarf oaks which produce the best gall nuts. The domestic animals are horses, of which the wandering tribes possess breeds of extraordinary speed and beauty; cattle, generally small and of inferior quality; asses and mules of large size and very serviceable; sheep and goats of several kinds, the broad-tailed variety of the former being found only in N. Syria; camels throughout the country; and the domesticated buffalo on the sea coast and in the Wady Ghab. Of wild animals, jackals, foxes, and hyenas are common in the desert mountains, and occasionally make a foray into the more populous districts; the Syrian bear has his home in Mt. Lebanon; wolves and wild boars in the northern forests, and the latter also occasionally further S.; deer are also found in the N., and antelopes in the desert regions; and hares, porcupines, and jerboas are abundant. There are no poisonous serpents. Silkworms are reared extensively in the mountainous districts. Turtles and tortoises are found in considerable numbers. Fish are abundant in some of the inland lakes, though not plentiful along the coast of the Mediterranean. The manufactures are few and coarse. (See TURKEY.)—The inhabitants are of a great variety of races and religions. The ruling race are the Osmanni Turks, who form but an insignificant portion of the Mohammedan population, who are mostly Arabs, and number about 1,500,000; they are bigoted and hostile to Christians, and are strict in their adherence to Soonnee or orthodox Islamism. There are 4 sects usually considered Mohammedan dissenters, though it is difficult to say whether all of them should be reckoned as Mohammedans or not. The Metawelis are the followers of Ali, the son-in-law of Mohammed, and are allied to the Sheeha or Shi-

ites of Persia; they are exceedingly strict in their ceremonial observances, and regard every thing touched by those not of their faith as unclean; they number about 30,000, and are found W. of the Orontes, and on the S. part of the Lebanon range. The Nusaireyeh or Ansairiyeh, inhabiting the mountains extending from the great valley N. of Lebanon to the gorge of the Orontes at Antioch, and numbering about 60,000, keep their religious views a secret; they are represented as holding to a mixture of paganism, Mohammedanism, and Christianity, are often called devil-worshippers, and acknowledge a belief in transmigration of souls; they are a wild, savage race, given to plunder and bloodshed. The Imailiyeh, occupying the mountains W. of Hamah, are few in number, and were originally Sheeahs; they are the descendants of the people known in the time of the crusades under the name of Assassins. (See ASSASSINS.) The 4th sect is the Druses, numbering about 70,000, and the most fanatical of all. (See DRUSES.) The largest of the nominally Christian sects is that of the Maronites, who are found chiefly in the Lebanon, though they have small communities in all the principal towns from Aleppo to Nazareth. They were estimated prior to the late civil war at about 225,000. The orthodox Greeks (Greeks in religion, but not generally in blood), numbering about 120,000, are scattered throughout the cities and more level portions of Syria, and engage in agriculture and trade; they have their worship in their own language. There are dissenters also from the Greek church, the Syrians or Jacobites, a mere handful, dwelling mostly N. and N. E. of Damascus. The Greek Catholic and Syrian Catholic churches acknowledge the pope, though in some particulars they approach more nearly to the Greek than the Roman church; they are about 40,000 in all, and embrace a large number of the more wealthy Christians in Syria. The Armenians are 50,000 or 60,000 in number. There are about 25,000 Jews in Syria; those in Palestine are immigrants from foreign countries, while those of Aleppo and Damascus are descendants of Jewish families who have resided there for many centuries. There are Mohammedan schools in the cities, and the Christian sects also maintain some schools. The children of the wealthy are frequently sent to France or England for education, but the great mass of the people are very illiterate.—Syria is remarkable as the seat of some of the earliest and most powerful nations of the East, and as having been the scene of the most extraordinary events of human history. Aram seems to have been the earliest name of the region, and the central part of it is designated in the Hebrew Scriptures as Aram Dammeseck, or the Aram of which Damascus was the capital. The manufactures of Damascus, its swords, its cutlery, its leather, and its rich perfumes, early gave it a reputation and prominence, which the ambition and energy of its long lines of kings great-

ly increased. The empire of the kings of Damascus gradually extended eastward over a part of the plain of Mesopotamia and westward to the mouth of the Orontes. It was finally overthrown by the Assyrians under Tiglath Pileser, about 750 B. C. The early inhabitants of northern Syria were descendants of Shem. From the Orontes southward, all of Palestine W. of the Jordan, and probably Gilead and the Hauran or Syria E. of the Jordan, was a region peopled by the Canaanites, descendants of Ham. The Phœnicians settled mainly along the coast of the Mediterranean, and became the earliest commercial nation of the world. Sidon, their first seat, is said by tradition to have been founded by Sidon, the oldest son of Ham; and colonies from it went forth to Tyre and Arvad, and thence to all portions of the Mediterranean and beyond. Phœnicia attained its greatest power about 1050 B. C., and it enjoyed uninterrupted prosperity for full 500 years, but was at last conquered by the Babylonians, and subsequently by the Persians. The southern parts of western and portions of eastern Palestine were inhabited by a great race, the Anakim and Rephaim, traces of whose cities yet remain in the Hauran. The S. W. coast was occupied by the Philistines, and the region adjoining the Dead sea to the E. by the Semitic Ammonites and Moabites. (See PALESTINE.) The equally Semitic Israelites emigrated from Egypt to Palestine during the 15th century B. C., and thenceforward for 1,600 years exerted a powerful influence in its history. (See HEBREWS.) The theocracy under which they existed for more than 400 years was terminated by the election of Saul as king in 1095, and the kingdom was divided in the reign of Rehobam, the grandson of his successor David. The 10 tribes, or Israel as they were distinctively termed, were conquered and carried into captivity by the Assyrians in 721 B. C., and their place supplied by colonists from Babylonia, Hamath, and elsewhere, who became the Samaritans of a subsequent era, and a few families of whom still exist on their ancient site. The kingdom of Judah fell before Nebuchadnezzar 188 years later, but after a 70 years' captivity the people were restored to their own land, and the second temple was built. Syria from this period, until Grecian power became paramount there, was governed by a Persian satrap resident at Damascus. The battle of Issus, 333 B. C., led to the subjection of Syria proper, Phœnicia, and Palestine to Alexander the Great. Tyre and Gaza alone stood out against him, and the former was taken by storm after a 7 months' siege. Jerusalem was threatened, but succeeded in securing his favor. On the death of Alexander, and after a long struggle of succession on the partition of his empire, the Ptolemies in Egypt received Palestine and Coele-Syria, and Seleucus Nicator northern Syria. He founded Antioch, near the mouth of the Orontes, and made it his capital; and for several centuries it was the great-

est of oriental cities. The kingdom of Syria continued flourishing under the Seleucids till about the close of the 3d century B. C. Antiochus the Great wrested Palestine and Oele-Syria from Egypt. The revolt of the Jews under the Asmonean family against Antiochus Epiphanes, after a struggle of 24 years, ended in their independence (143). (See ANTIOCHUS, DEMETRIUS SOTER, HEBREWS, and SELEUCUS.) About 68 B. C. Syria became a Roman province, and subsequently was divided into several provinces; the Herodian family ruled over Judæa and some adjoining districts, while northern Syria and the coast were under Roman proconsuls. After the destruction of Jerusalem by Titus, the whole of Syria, including Judæa, was ruled by a Roman prefect, and Antioch was the capital. It continued under the Roman and Byzantine empire till its conquest by Chosroes II. in the beginning of the 7th century, followed by that of the Mohammedans, A. D. 634. The spread of Christianity in Syria was rapid, and the great cities of the province, in their costly cathedrals, churches, and episcopal palaces, gave ample evidence of the opulence of its adherents; and fierce theological contests were waged with the western and African bishops. In 654 Damascus again became the capital of Syria and of the great Mohammedan empire. The great cities of Syria, which had scarcely yielded to any in the world in point of splendor, waned under the withering influence of Islamism, and of them all Damascus alone now retains any measure of its former grandeur. In 750 the capital was removed first to Oufah and afterward to Bagdad, and Syria thenceforth became only a province of the empire of the caliphs. About the middle of the 10th century the rival Mohammedan dynasty of the Fatimites in Egypt conquered it, and toward the close of the 11th the Seljook Turks made it a part of their empire. The cruelties perpetrated by these fanatics on Christian pilgrims visiting the Holy Land led to the crusades, and in 1099 Jerusalem was taken by storm, and the whole of Syria except Damascus and a part of Mesopotamia conquered by the Christian princes, and divided into principalities; Godfrey was chosen king of Jerusalem, Bohemond reigned at Antioch, Baldwin at Edessa, and the count of Toulouse at Tripoli. Their rule was of short duration; after repeated attacks by Nouredin and his successors, it was overthrown by Saladin in 1187. The numerous crusades which followed resulted only in their regaining a few points, and in the temporary acquisition of Jerusalem by treaty in 1229, only to be attacked and plundered by the Tartars and the troops of Melek ed-Dhabn, and the final occupation of the whole country by the Mamelukes in 1291. (See EGYPT.) For two centuries the unfortunate country was the prey of the two contending Tartar powers, Tamerlane and his successors and the Mameluke sovereigns of Egypt. In 1517 it was conquered by Sultan Selim I., and

from that time to our own has formed a part of the Ottoman empire. In 1832 Ibrahim Pasha conquered Syria for his father Mehemet Ali, pasha of Egypt; but in 1841, through the armed intervention of England, it was restored to the sultan. In July, 1860, an insurrection occurred on the part of the Mohammedans at Damascus, in which many Christians were slain, the Dutch consul killed, and the American consul wounded. This was followed, as it had frequently been preceded, by similar disturbances in Mt. Lebanon, between the Druses and Maronites, and a predatory conflict of several months' duration, in which nearly 150 villages were destroyed. France and England finally interfered, the outbreak was suppressed, and the prime movers were brought to punishment.

SYRIAC LANGUAGE AND LITERATURE. The Syriac language belongs to the northern or Aramaic branch of the Semitic family, which branch includes, beside it, the closely related Chaldean, or dialect of Mesopotamia. In writing it various forms of character are used, all of them, however, of kindred origin, and coming from the same source whence are derived the other Semitic alphabets. The oldest character is the Palmyrene, represented by sundry inscriptions dating from soon after the time of Christ; with this is most nearly connected the common square Hebrew character, used by the Jews from the Babylonian captivity down to the present time. Next in age is the Estrangelo alphabet, commonly employed by the Syrians till the 8th or 9th century; out of this grew, on the one hand, the Cufic, the parent of all the modern forms of the Arabic; while, on the other hand, through the Nestorian missions in High Asia, it was communicated to Tartar tribes, and grew into the modern Mongol and Mantchoo alphabets. The common modern Syriac alphabet is an adaptation of the Estrangelo to an easier and more rapid style of writing; it began to come into use in the 5th and 6th centuries, and by degrees crowded out its predecessor, which was at last employed only for headings and such like purposes. Finally, we have the Nestorian character, still in common use with the modern Nestorian Christians; it is heavier and squarer than the last named, and less altered from their common mother, the Estrangelo. All these alphabets contain the same 22 characters with the Phœnician and the Hebrew.—The position of Syria, in contact on all sides with powerful nations and developed civilizations of other races, and its subjection in turn to Persian, Greek, and Roman domination before the period of our first acquaintance with its language, are doubtless the reasons why the latter presents us the Semitic type in less purity than the other dialects of the family. It contains many Greek and Latin words, chiefly nouns, but sometimes other parts of speech, even particles; it admits to a slight extent of composition of words; it has also partly filled out the scanty structure of the Semitic verb

with forms of periphrastic origin. Thus, beside the usual perfect and imperfect (or preterite and future), each of which is capable of standing for time past, present, or future, it has a distinctive present, formed by a participle and following pronoun; an imperfect, formed of a participle and the verb to be; a pluperfect, formed of the perfect (or preterite) and the verb to be; and even a future, with the adjective ready, about to. Of the Semitic conjugations, the Syriac has but 8, each with its passive; the 3d and 8d are hardly distinguished in meaning, both expressing intensive or causative action. The dual number, both in nouns and verbs, has entirely disappeared. While the language has gained something in point of precision, it has lost in simplicity, conciseness, and force, and makes the impression, as Renan says, of a tongue "dull, clear, prolix, without harmony, loaded with foreign words," and in which "the relations of ideas, so elegantly expressed in Hebrew by a small number of flexions, are lengthily and heavily set forth by the use of particles and circumlocutions."—The ancient Syriac was a vernacular dialect during the first centuries after Christ; after being raised to the rank of a cultivated literary language, chiefly in connection with the translation of the Bible and the propagation of Christianity, it maintained itself as such, unaltered, throughout the whole period of growth of the Syriac literature; and it is still the sacred language of the scattered bodies of Christians in Asia representing the ancient Syriac church, as the Nestorians and Maronites, and the St. Thomas Christians of India; it is no longer properly understood, however, even by the best instructed among them. But the popular dialects, beside undergoing inevitable change and corruption, began, after the Arab conquest and the spread of Islam over the country, first to be filled with Arabic words, then to be crowded out of use and replaced by the Arabic, until, probably in the 12th and 13th centuries, Syriac almost entirely disappeared as a spoken tongue, being retained only by a few scattered tribes in a greatly corrupted form, and principally by the Nestorian Christians of Koordistan and Persia. The vernacular dialect of these scanty remains of the once powerful and active sect of Nestorians has been lately, by the efforts of the American missionaries at Ooroomiah, raised to the rank of a written and printed language, with a Christian literature, school and scientific books, periodicals, &c. A grammar of it, by the Rev. D. T. Stoddard, has been published by the American oriental society (in its "Journal," vol. v., 1856, and as a separate work); it furnishes a very curious and interesting illustration of how even a Semitic idiom may become changed, mixed, and corrupted, when left to grow up uncultivated during a long period in the midst of foreign influences.—The Syriac literature is all later than the Christian era, and is a Christian literature, composed under Greek influence and after Greek models, so

that it has a less independent interest than the other principal Semitic literatures; but, beside the important part it has played as the intermediary between Greek and Moslem science and philosophy, it is a source of very valuable historical information, especially as regards the history of the early Christian church. The oldest Syriac work still existing is the translation of nearly the whole Bible, of unknown authorship, commonly called the Peshito; it is supposed to have been made not later than A. D. 200. The earliest authors whose names, with fragments of their works, have come down to us, are a few years older; they are Bardesanes and his son Harmonius. Beside philosophical works, they composed the first hymns in the language, and fixed its poetic style, giving it a properly metrical form, dependent on accent and number of syllables, with occasional rhyme; it was the first time any Semitic dialect had been subjected to such rules. But the most prominent early Syriac author is St. Ephraem, or Ephraem Syrus, of the middle of the 4th century; with him commences the full career of the Syriac literature, which continued uninterrupted until the 9th century. It concerned itself especially with religion, the translating and commenting of the Scriptures, dogmatic and polemical theology, martyrologies and liturgies, but embraced also history, philosophy, grammar, and the natural sciences; medicine, the most important science in the Orient, was for many centuries entirely in the hands of the Syrians. A great part of this literature has been lost, and what remains has as yet been but partially worked up and made accessible. It may be said to have done its principal work in the 8th and 9th centuries, in introducing classical learning to the knowledge of the Arabs. These became the scholars of the Syrians in every department, and their translations of Greek authors are supposed to have been made, especially at the outset, almost altogether from Syriac versions and by Syrian scholars. But the Arabs soon surpassed their Syrian teachers, and became their instructors in turn; and the greatly superior vigor and ability of the new Moslem literature enabled it to crowd out of favor and out of existence that upon which it was founded, as the Arabic language crowded out the Syriac idioms. The grammatical study and culture of the Syriac began after the founding of the famous school of Edessa, long a chief centre of oriental learning, in the 5th century. The works of previous laborers in this field were effaced by those of Jacob of Edessa, of the 7th century, whose authority gave the classical and sacred dialect its final form. From his time the series of native grammarians and lexicographers is almost unbroken; of most note among them are Elias of Nisibis (11th century), John Barzugbi (beginning of the 13th century), and Barhebraeus, known also as Arabic author by the name of Abulfaraj (13th century); of lexicographers, Bar-Ali and Bar-Bahlul (of the 9th and 10th cen-

strict search of his abode and papers was executed by the Austrian police, which, together with the simultaneous loss of a friend, is said to have rendered him again insane. Soon after he was found dead in his room, killed by a pistol ball. The universal manifestation of national grief and indignation which followed the receipt of the news of this catastrophe in Hungary became so overwhelming, that even before the celebrations in honor of his memory were over the Austrian government was again compelled to yield; and the first anniversary of Széchenyi's death was celebrated by a new national diet assembled at Pesth (April, 1861).

SZEGEDIN (Hun. *Szeged*), a free royal town of Hungary, capital of the county of Ósöngrád, situated on the right bank of the Theiss, opposite the mouth of the Maros, 60 m. W. from Arad and 89 m. S. E. from Pesth; pop. in 1857, 62,700, chiefly Magyars and Slavi. It stands in a marsh, and is divided into the town proper and the upper and lower suburbs. The river is crossed by a bridge of boats, and the town defended by an old fortress built by the Turks in the 16th century, which is surrounded by walls and ditches and entered by two bridges, and contains extensive barracks, a house of correction, and a church of its own. The corn market stands by itself, and consists of a row of houses, the town house, large barracks, and several factories. The principal manufactures are different kinds of cloth, tobacco, soda, and soap; and vessels for the navigation of the Theiss are built in considerable numbers. The town is connected by railway with Pesth, as well as with Temesvár. It was a place of considerable importance during the Turkish sway in Hungary, and in the summer of 1849, for a short time, the seat of the revolutionary government and the national assembly.

SZEKLER. See TRANSYLVANIA.

SZEMERE, **BERTALAN**, a Hungarian statesman and author, born at Vata, in the county of Borsod, Aug. 24, 1812. He received his early education at Miskolcz and Kásmark, went through a course of philosophical and legal studies at Patak and Presburg, in 1836-'7 travelled through Germany, Belgium, Holland, Great Britain, France, and Switzerland, subsequently held various offices in his native coun-

ty, and was elected by the same to the diet of 1843-'4 and 1847-'8. His *Utazás külföldön* ("Travels Abroad," 2 vols., Pesth, 1840), two pamphlets advocating the introduction of the Pennsylvania prison system and the abolition of capital punishment, and his boldness and eloquence in defence of popular and national rights, had made him a favorite of the public, as well as one of the principal leaders of the opposition party, when the revolution of 1848 called the latter to the administration of the country. Szemere was appointed minister of the interior in the Batthyányi cabinet, being also elected representative of Borsod in the national assembly of Pesth; became subsequently a member of the "committee of defence," officiated for some months as commissary of the revolutionary government in upper Hungary, and on the declaration of independence in Debreczin was chosen by Kossuth president of the new ministry, with the portfolio of the interior. In all these capacities he displayed an untiring activity and great energy, beside being conspicuous for his democratic and republican demonstrations. He opposed the transfer of dictatorial powers to Görgey, and after the surrender of the latter escaped to Constantinople, and thence went to Paris, where he has since resided. In exile he published, beside some minor writings, *L. Batthyányi*, *A. Görgei* and *L. Kossuth* (Hamburg, 1851), in which he vehemently assails the two latter, and "Hungary from 1848 to 1860," in letters to Cobden, Lord Palmerston, and Count Cavour (London, 1860). —Two elder members of the same family, **PÁL** (born 1785) and **MIKLÓS** (born 1804), enjoy a considerable reputation as poets.

SZIGLIGETI, **JÓZSEF**, a Hungarian dramatist, born in Grosswardein in 1814. He studied in his native town, and at the age of 20 joined a company of actors at Buda, with whom, on the foundation of the national theatre at Pesth, he permanently attached himself to this institution. Not conspicuous as an actor, he has proved a very successful author of plays, especially of the light and popular kind. Among his numerous productions are: *Vasul*, *Al Endre* ("Pseudo-Andrew"), *Széköt katoná* ("The Deserter"), *Két pisztoly* ("Two Pistols"), and *Zsidó* ("The Jew").

T

T, the 20th letter and 16th consonant of the English and other alphabets derived from the Roman, the 19th of the Greek (*tau*), and the 9th of the Hebrew (*tet* or *teth*). It is of the denti-lingual class, and represents the sound produced by a forcible emission of the breath after placing the tongue against the roof of the mouth near the roots of the teeth. This forcible emission of the breath is the principal distinction between the sounds of *t* and its son-

orous counterpart *d*. In etymology it is interchangeable with *d*, and sometimes with *th*, *p*, *s*, and *l*. By itself it has but one sound; but combined with *h*, it forms a compound sound as in the word *thigh*, which sound the Anglo-Saxons represented by *ð*, the Greeks by *θ* (*theta*), and the Hebrews by *ת* (*taa* or *tau*); or as in the word *thy*, which sound the Anglo-Saxons represented by *þ*; for neither of these sounds has the English a separate char-

acter. In French *t* is dropped in many words from the Latin where it is preceded and followed by a vowel; as in *père, mère, vie*, from *pater, mater, vita*; also from the termination of many words. In French and English, before the vowel *i*, *t* has the sound of *sh*, as in *fruition*.—As a Greek numeral *τ* stood for 800, *ρ* for 800,000. Among the Latins *T* represented 160, and with a dash above it (*τ*) 160,000. As an abbreviation it stands for *theologia*, as in S. T. D., *sacra theologia doctor*; and in ancient writings, monuments, or coins, for Titus, Titius, Tullius, and sometimes *tribunus*. (See D.)

TABASCO, a S. E. state of Mexico, bounded N. by the gulf of Mexico, E. by Yucatan, S. by Chiapas and Guatemala, and W. by the territory of Tehuantepec; area, 18,996 sq. m.; pop. 75,901, chiefly Indians. The coast is indented by several bays and lagoons, and there are some islands toward its E. extremity, the most important of which are Laguna, Carmen, and Puerto Real. The surface is generally flat and in some places marshy, and there are several small lakes. The rivers, with the exception of the Usumasinta and Tabasco, are generally small, and they all overflow their banks at certain seasons. The climate is hot and unhealthy; and between September and March gales of wind render navigation dangerous even on the rivers. Oak, cedar, and mahogany abound. Cacao, coffee, pepper, sugar cane, palmetto, tobacco, maize, and rice are cultivated. Capital, San Juan Bantista.

TABERNAACLE (Lat. *tabernaculum*, tent; Heb. *ohel*), the name of the portable sanctuary which the Israelites carried with them in their migrations through the desert, and which, after the conquest of Canaan, was set up in various towns of Palestine until the time of Solomon, when it was replaced by the temple of Jerusalem. It was constructed, by order of Moses, by Bezaleel and Aholiab, and set up for the first time on the first day of the first month in the second year after leaving Egypt. Its framework consisted of 48 perpendicular gilded boards of acacia wood, which were kept together by golden rings and fixed into silver sockets. Over these boards 4 coverings were spread. The entrance, which was turned toward the east, was closed by means of a splendid curtain, supported by 6 columns. The interior was divided by a curtain into two rooms, the sanctuary and the holy of holies. In the sanctuary was placed, on the north, the table with the 12 loaves of shew bread (see *SHew BREAD*); toward the south the golden candlestick; and in the middle the altar of incense. In the holy of holies stood the ark of the covenant. The tabernacle was surrounded by a kind of courtyard which was 100 cubits long and 50 wide. The typical significance of the tabernacle has been, ever since the times of Philo and Josephus, a subject of investigation. The most important treatises on the subject in modern times are by Creuzer, *Symbolik des*

mosaischen Cultus (2 vols., Heidelberg, 1837-'9), and Friedrich, *Symbolik der mosaischen Stiftshütte* (Leipsic, 1841).

TABERNACLES, FEAST OF (Heb. *'hag hasukoth*), one of the 3 great festivals of the Jews, observed after harvest, and commencing on the 15th day of the month Tisri. It was instituted to preserve the remembrance of the goodness of God, who protected his people in the wilderness when they dwelt in tents or booths. It continued 8 (among the Jews in exile 9) days, the first and last (in exile the two first and two last) of which were the most important and solemn. To the ceremonies of the festival belongs the waving toward the 4 quarters of the world of fine fruits and leafy branches amid the singing of liturgical songs, commonly called, from the repetition of the words *hosia' na* (Oh save!), Hosanna. On the 7th day this was repeated, for the last time, with greater solemnity. During the first 7 days the living in booths was obligatory, which is still partially observed by the Jews in most countries. Sacrifices took place in the temple, and in later times also a ceremony of "pouring water" on the sacrifice, and a great illumination of the outer court, connected with dances by torchlight.

TABOO, a word formerly used by the Polynesian islanders to indicate both a religious consecration and a political prohibition exercised by the chiefs. All things reserved for the service of their idols were *taboo*, and no person but the priests, and especially no woman, might touch them; lands were also thus consecrated, and when the sign of taboo was raised over them, no profane foot might intrude. The chiefs were also accustomed to taboo certain articles of food or clothing which they desired to reserve for their own use, and thus often occasioned great distress by depriving the common people of them. It is used in English to signify a total prohibition of intercourse with or approach to the thing tabooed.

TABOR, MOUNT (Gr. *Αραβυρ*; now *Jebel at-Tur*), an insulated eminence in the plain of Esdraelon, about 6 m. S. E. from Nazareth, in Galilee, commonly regarded as the scene of the Saviour's transfiguration. It is about 1,000 feet high, composed entirely of limestone, and its sides are covered up to the summit with the valonia oak, wild pistachios, myrtles, and other shrubs. Its summit is a plateau of some 600 yards in extent from N. to S. and about half as much across. All around this plain there are traces of an ancient wall, and below it on the S. E. side of the hill are the ruins of a fortification, a gateway of Saracenic architecture called "the gate of the wind," and a small vault where the Latin monks from Nazareth celebrate an annual mass in memory of the transfiguration. Among the ruins of a church on the N. side of the mountain the Greeks observe the same festival. Tabor is several times mentioned in the Old Testament, and before it Deborah and Barak assembled the warriors of

Israel previous to the battle with Sisera. There was upon it a city of the Levites of the tribe of Zebulun, which was taken and fortified by Antiochus the Great, 218 B. C. In 58 B. C. a battle was fought near it between the Romans under the proconsul Gabinus and the Jews under Alexander the son of Aristobulus, in which 10,000 Jews were slain. Tabor is not named in the New Testament, and was first mentioned as the place of the transfiguration in the 4th century. At the foot of it the crusaders several times fought the Moslems, and Napoleon gained there a victory over the Turks.

TABORITES. See HUSS, vol. ix. p. 395.

TABRIZ, TABREEZ, or TAUREZ, a town of Persia, capital of the province of Azerbaijan, situated on the left bank of the Aigi, 36 m. from its entrance into Lake Ooroomiah; pop. 80,000. It stands in a plain 4,800 feet above the level of the sea, and has ranges of bare rugged hills on 8 sides. The surrounding country is very fertile. The town is defended by a wall of sun-dried bricks, about 8½ m. in circuit, and entered by 7 gates. The most remarkable building is the citadel, which was originally a mosque, and is 600 years old; it is a lofty edifice, and contains both a cannon foundry and barracks within its walls. In many of the gardens there are ruins of magnificent buildings. Tabriz has manufactories of cotton and silk goods. It is said to have been founded by the wife of Haroun al Rashid, A. D. 791. It has been several times captured by the Turks, and frequently severely damaged by earthquakes.

TACAMAHAC. See POPLAR.

TACITUS, CAIUS CORNELIUS, a Roman historian, born probably between A. D. 50 and 55, died probably in the early part of the reign of Hadrian. The few details of his personal history are to be gleaned from scattered passages in his own writings and those of his friend Pliny the Younger, and most of these can be stated only on conjecture. At about the age of 25 he was appointed to an office, supposed to have been the quaestorship, by Vespasian; he was further promoted by Titus; and in 88 he held a praetorship under Domitian. As *sacerdos quindecimviralis* he also assisted in this year at the celebration of the secular games. In 97 he was *consul suffectus*, and in 100 he assisted Pliny, who speaks in exalted terms of his oratorical powers, in the prosecution of Marius Priscus for gross misconduct during his proconsulship in Africa. There is no further record of his life, which under the orderly sway of Trajan and Hadrian was probably passed in the peaceful pursuit of literature. In 78 he was married to the daughter of Oneius Julius Agricola, to whose virtues and eminent military and administrative abilities he has paid in his *Vita Agricola* an affectionate tribute. His literary remains comprise the *Dialogus de Oratoribus*, the *Vita Agricola* above mentioned, the *Germania*, the *Historia*, and the *Annales*, which were probably written in the order here

designated. The *Dialogus de Oratoribus*, treating of the causes of the decline of eloquence in Rome, was written in the 6th year of Vespasian, and is distinguished by a diffuse and easy style, very different from that adopted in his later works. It was formerly by no means universally ascribed to Tacitus, but commentators now generally concur in considering it his work. The *Vita Agricola*, written probably under Domitian and published under Nerva in 97, has been greatly admired as a specimen of biography, although the style is sometimes difficult, owing to the conciseness of statement and the corruptions of the text. It is not contained in the earliest editions of Tacitus. The *Germania*, written in 98, is a detailed account of the manners and customs of the German tribes, derived principally from the statements of traders and soldiers. Its geographical value is so slight that the credibility of the whole work has been questioned, though without sufficient reason, it would seem, as the author evidently gave most attention to the social and political aspects of his subject. The *Historia* embraces the period from the death of Nero (68) to the death of Domitian (96), and must have been an elaborate work, as the first 4 books and a part of the 5th, the only portions now extant, carry the narrative no further than the commencement of the siege of Jerusalem by Titus in A. D. 69. In point of style they are the most finished of all his productions. The *Annales*, the work of his mature years, commenced with the death of Augustus in A. D. 14, and extend to the death of Nero, embracing a period of 54 years; and of the 16 books in which they were originally comprised only the first 4, part of the 5th, the 6th, the latter part of the 11th, the 12th, 13th, 14th, 15th, and the first part of the 16th are extant. The first 5 books were discovered early in the 16th century in the abbey of Corvey, Westphalia, and were first published in Rome in 1515. It being the purpose of the author to show the condition of the empire under the Caesars, the emperor is made the central figure around which the events are grouped, and those happening outside of the immediate atmosphere of the imperial court are made subordinate to the general narrative. A method of treatment like this, directly biographical and only indirectly political or historical, necessitates the elaboration of striking incidents and catastrophes, and no effort seems to have been spared by Tacitus to impart dramatic point to his work. The motives of human conduct are laid bare with wonderful skill, the good and the bad men of the age pass in review before the reader, and the great events of each reign loom forth in a sort of lurid splendor. The style, though labored, is concise and vigorous, and every passage is impressed with a melancholy, almost tragic earnestness, characteristic of a man who writes with a consciousness of the social misery he depicts, and with a determination to speak the truth. Hence Bossuet has called Tacitus "the

most dignified of historians," and his annals, if evincing occasionally a too evident aiming at startling contrasts, must be considered on the whole the most philosophical history which antiquity has bequeathed to us. Bötticher, in his *De Vita, Scriptis et Stilo Taciti*, has classed the peculiarities of Tacitus under 3 heads: love of variety, brevity and force of expression, and a certain poetical coloring of the language, characteristic of the writers of the later period of Roman literature. It may be added that the difficulties of his style have at all times rendered him accessible to a limited class of readers. The *editio princeps* of Tacitus, which is far from complete, was printed at Venice in 1470 by Vindelin de Spira; and of the numerous subsequent editions that of Ernesti by Oberlin (8vo., Leipsic, 1801), with the notes by Lipsius, is esteemed the best. Separate editions of his several works are also numerous. Of translations, that in Italian by Davanzati is highly esteemed; the English versions by Gordon and Murphy have little merit.

TACITUS, MARCUS CLAUDIUS, a Roman emperor, born in Interamna (now Terni), Umbria, about A. D. 200, died at Tyana, in Cappadocia, April 9, 276. Previous to the assassination of the emperor Aurelian in March, 275, he held various important civil offices, the last being that of consul in 273, and was well known for his love of letters, his great wealth, and his integrity. In Sept. 276, after 6 months of what Gibbon calls a "tranquil anarchy," during which the army and the senate mutually solicited each other to select a successor to the vacant throne, Tacitus was unanimously elected emperor by the latter body. He instituted a few domestic reforms, and attempted to revive the authority of the senate; but he died within little more than half a year from the commencement of his reign. According to one account he was assassinated by the soldiers. He claimed descent from the historian Tacitus, whose works he ordered to be placed in all public libraries, and to be multiplied to the extent of 10 copies a year at the public expense.

TADMOR. See **PALMYRA**.

TADPOLE. See **FROG**.

TÆL, **TAL**, or **TAYEL**, a money of account in China, Japan, Siam, and Sumatra. It is in China equivalent to 1,000 cash, and is usually reckoned in the East India company's accounts at 6s. 8d. or \$1.61, though it really varies from \$1.44 to \$1.60. Its value is much higher in Sumatra, where it is equivalent to 64 copangs, and as a money of account to £1 2s. or \$5.32. In Japan its value is much the same as in China. The Dutch reckon it at 6s. 2d. sterling, or \$1.49.

TÆNARUM, now **CAPE MATAPAN**, a promontory of Laconia, in ancient Greece, at the S. extremity of the Peloponnesus, celebrated for a temple of Neptune possessing the right of asylum, for a cave through which Hercules was said to have dragged Cerberus to the upper world, and for a statue of Arion seated on a dolphin, to commemorate his landing on

the promontory after his miraculous preservation by that animal. In the time of the Romans the place was famous for marble quarries. There was a town here called Tænarum or Tænarus, afterward Cænepolia, which was variously represented as having been built by Tænarus, a son of Jupiter, by Elatus, and by Icarus.

TAFILET, or **TAFILELT**, a division of Morocco, lying E. of the chain of the Atlas mountains, bounded N. by Fez and S. by the desert of Sahara. It consists of a vast plain, and is traversed by two rivers, both of which are lost in the sands of the desert. Wheat and barley are cultivated on the banks of the rivers, but dates are the chief product. The inhabitants have large herds of sheep and goats, and stuffs and carpets are manufactured from the wool. There are mines of antimony and lead.—**TAFILET**, the chief town, situated in lat. 31° 45' N., long. 4° 5' W., 230 m. E. S. E. from Morocco, is formed by a collection of several villages; pop. 10,000. The inhabitants are mostly Berbers. A considerable trade is carried on by caravans with Timbuctoo.

TAGANROG, a fortified town of European Russia, government of Ekaterinoslav, situated near the N. E. extremity of the sea of Azof, 28 m. W. N. W. from Azof, and 68 m. W. S. W. from Novo-Tcherkask; pop. about 17,000. It stands on a rocky promontory opposite the mouth of the Don, and is a place of considerable strength. Earthenware, cordage, tallow, canvas, and leather are manufactured; there is a bell foundry, and ship building is extensively carried on. The harbor, though the deepest in the sea of Azof, cannot be entered by vessels drawing over 10 feet. Taganrog was founded in 1688 by Peter the Great. The town contains a monument to Alexander I., who died there in 1825. In July, 1855, it was bombarded by the allied gun boats.

TAGLIONI, **MARIE**, an Italian dancer, born in Stockholm in 1804. She belongs to a family of dancers, her father, a native of Milan, having held the position of ballet master successively at Stockholm, Cassel, and Warsaw. She made her début at Vienna in June, 1822, and between 1827 and 1832 performed in Paris with great success, surpassing all her contemporaries in agility and gracefulness. Thenceforth for 15 years she was esteemed the first ballet dancer in Europe, in the chief theatres of which she fulfilled repeated engagements. She retired from the stage in 1847 with a handsome fortune, and went to reside in Italy, where she possesses a villa on the lake of Como, and a palace in Venice. *La sylphide* and *La fille du Danube* are the ballets in which she gained her greatest triumphs. In 1832 she was married to Count Gilbert de Voisins.

TAGUA PLANT. See **PALM**, vol. xii. p. 703.

TAGUAN. See **FLYING SQUIRREL**.

TAGUS (Span. *Tajo*; Port. *Tejo*), a river of Spain and Portugal, the longest in the peninsula, and dividing it into two nearly equal parts. It takes its rise in the Sierra De Cuenca, in the

province of Guadalajara near the border of Teruel, and flows N. W. for about 24 m.; then nearly W. for 20 m., receiving the waters of the Molina; then S. W. for a little more than 70 m., the Guadiela and other streams augmenting its volume. It then takes nearly a due W. course till it becomes for about 20 m. the boundary of Portugal, its principal affluents being the Jarama, which joins it a little below Aranjuez, the Cedron, the Guadarrama, the Alberche, the Alagon, and numerous smaller streams. Entering Portugal, it inclines more and more to the S. W., receiving below Abrantes the Zézere, and from that point becoming navigable for vessels of 150 tons. In the lower part of its course numerous islands occur, and for about 30 m. it spreads out into a table-like basin, 12 m. or more in width; but as it approaches Lisbon the hills on either side close up the valley, and at its mouth it is not over a mile wide. The banks of the Tagus are generally rugged and precipitous, and the plains through which it flows are dry and barren. It is only navigable a short distance and for small vessels. Lisbon, Santarem, and Abrantes in Portugal, and Talavera de la Reyna and Toledo in Spain, are on its banks; and Madrid, Guadalajara, &c., are in its basin. Its length is about 540 m.

TAHITI. See SOCIETY ISLANDS.

TAILLANDIER, RENÉ GASPARD ERNEST, called SAINT RENÉ, a French author, born in Paris in 1817. He finished his education at Heidelberg, in 1841 was appointed adjunct professor of literature in the faculty of Strasbourg, and in 1850 became titular professor in that of Montpellier. At the commencement of his literary career he assumed the *nom de plume* of Saint René, by which he has ever since been known. His principal works are: *Des écrivains sacrés au XIX^e siècle* (1842); *Scot Érigène et la philosophie scolastique* (1848); *Histoire de la Jeune Allemagne, études littéraires* (1849); *Études sur la révolution en Allemagne* (2 vols., 1853); *Allemagne et Russie, études historiques et littéraires* (8vo.); and *Le poète du Caucase, ou la vie et les œuvres de Michel Lermontoff* (1856). Since 1848 M. Taillandier has been a constant contributor to the *Revue des deux mondes*.

TAILOR BIRD, a name given to several species of East Indian warblers of the subfamily *malurina*, and especially to those of the genus *orthotomus* (Horsf.). In this genus the bill is slightly curved, with the tip entire; wings short and rounded, the 4th to the 8th quills equal and longest; tail long and graduated; hind toe nearly as long as the middle, and with a long, strong claw. They are familiar birds, hopping about cultivated fields and from bush to bush in search of insects and larvæ on which they feed, jerking the tail over the back in a very singular manner. The best known species is the long-tailed tailor bird (*O. longicaudus*, Horsf.), about the size of a sparrow, greenish above and white below, with chestnut crown and brown tail and wings. Its

nest is a very remarkable specimen of bird architecture, being made of the living leaves of the mango and other trees, which it sews together with fibres or cotton thread, forming a hanging pouch supported by the footstalk still attached to the parent tree; the pouch is open at the top, and the nest is placed at the bottom, composed of cotton, flax, hair, and other soft substances, neatly woven together; in this hanging structure the young are safe from monkeys, snakes, and other enemies.

TAINE, HIPPOLYTE ADOLPHE, a French writer, born at Vouziers, Ardennes, April 21, 1828. He was educated at the Bourbon college, was for 5 years connected with the normal school, and since 1858 has devoted himself to literary pursuits. His *Essai sur Vite Live* (18mo., 1854) received a prize from the French academy. He has also written *Voyage aux eaux des Pyrénées* (18mo., 1855); *Les philosophes Français du XIX^e siècle* (18mo., 1856); and *Essai de critique et d'histoire* (18mo., 1857); and is a regular contributor to the *Revue des deux mondes*.

TALavera DE LA REYNA (anc. *Talabriga*), a town of Spain, New Castile, province of Toledo, situated in a plain of great extent on the Tagus, 64 m. S. W. from Madrid; pop. about 6,000. The town was formerly divided into sections by 8 walls, 2 of which still remain; and part of the old ramparts is in tolerable preservation. It is a place of great antiquity, and was the scene of many conflicts between the Moors and Christians. On July 27 and 28, 1809, a battle was fought in the immediate vicinity, between the French, 56,000 strong, under Victor, Jourdan, and Sebastiani, and the English, 26,000 strong, and their allies numbering about 39,000, under Sir Arthur Wellesley. The French, after repeated desperate attempts to drive the British from their position, were at length repulsed with the loss of 20 guns and nearly $\frac{1}{3}$ of their numbers.

TALBOT. I. An E. co. of Md., bounded W. by Chesapeake bay and S. and E. by the Choptank river; area, 250 sq. m.; pop. in 1860, 14,795, of whom 8,725 were slaves. The surface is generally level and the soil highly fertile. The productions in 1850 were 272,963 bushels of wheat, 621,980 of Indian corn, 48,917 of potatoes, and 97,585 lbs. of butter. There were 8 ship yards, 6 grist mills, 5 saw mills, 28 churches, 2 newspaper offices, and 985 pupils attending public schools. Capital, Easton. II. A W. co. of Ga., bounded N. E. by Flint river and drained by several large creeks; area, 524 sq. m.; pop. in 1860, 18,617, of whom 8,603 were slaves. The surface is hilly and the soil good. The productions in 1850 were 655,802 bushels of Indian corn, 89,185 of oats, 162,819 of sweet potatoes, and 18,732 bales of cotton. There were 11 grist mills, 5 saw mills, 10 tanneries, 25 churches, and 492 pupils attending public schools. It is crossed in the S. E. by the Muscogee railroad. Capital, Talbotton.

TALBOT, SILAS, an American military and naval officer, born in Rhode Island about 1750,

died in New York, June 30, 1818. Upon the breaking out of the revolutionary war he was commissioned a captain in one of the Rhode Island regiments, and, after participating in the siege of Boston, accompanied the army in 1776 to New York. For the skill with which he directed certain operations against the British shipping in the harbor he received from congress a major's commission. He participated in the memorable defence of Fort Mifflin, Nov. 1777, where, with a severe wound in the thigh and a shattered wrist, he continued fighting until the evacuation of the work; and in 1778 he rendered valuable assistance to Gen. Sullivan by transporting the American forces from the mainland to the upper end of the island of Rhode Island. One of the most dashing exploits of the war was his capture in 1778 of the British floating battery Pigot, of 22 guns, anchored in one of the channels commanding the approach to Newport. In Sept. 1779, he was commissioned a captain in the navy, and, after cruising with success against British commerce, was in 1780 captured by a British fleet and confined in the Jersey prison ship. He was afterward removed to England, and in 1781 was exchanged. Upon the reorganization of the navy in 1794, he was again called into the public service, and superintended the construction of the frigate *Constitution* ("Old Ironsides"), which in 1799 was his flag ship during a cruise in the West Indies. He resigned his commission in 1801, and passed the remainder of his life in the city of New York.—See "Life of Silas Talbot," by H. T. Tuckerman (18mo., New York, 1850).

TALO. See *STREATITE*.

TALENT (Gr. *ταλαντον*; Lat. *talentum*), a term originally applied by the ancient Greeks to a balance for weighing, afterward to the substance weighed, and finally to the weight itself. In the system of weights in use the talent was of the highest denomination, and was equivalent to 50 minas, each of which was equal to 100 drachmas, and each of these to 6 oboli. The values of these weights remained constant in relation to each other, while that of the units of the measure varied in different times and in different places. The system of money being based upon the weight of silver, the names of the weights employed came to be used as money values, in the same way as the English pound originally represented a pound weight of silver. No coins however are known to have been made larger than the tetradrachma, and the mina and talent were moneys of account only. The talent, when spoken of by ancient Greek writers, and not otherwise designated, is understood to refer to the Attic talent, the weight of which has been calculated from ancient coins which have been preserved, and, according to Dr. Arbuthnot, was equal to 59 lbs. 11 oz. 17½ gr. troy weight. Previous to the time of Solon, however, who lowered the standard of money, the weight of the talent was to that named as 100 : 78. The value of

the later talent has been estimated at about £198, or about \$958. The Euboic talent is generally rated as of the same value as the Attic; and the Romans reckoned the weight of each as equal to 80 Roman pounds. A talent of *Egina*, which in very early times was the standard over the greater part of Greece, has been generally considered to have been in proportion to the Attic, as 5 to 8. Various other talents are named by the ancient writers, the comparative values of which have been treated in the works of Bockh and of Hussey, in Gibbon's "Miscellaneous Works" (iii. 410), and in Dr. Arbuthnot's "Tables of Ancient Coins, Weights, and Measures." The gold talent of the Greeks, or the Sicilian talent, which is the talent always meant in Homer, contained about 4 oz. and 71 gr. avoirdupois of gold, and is supposed to have been called talent from the value of the gold being equal to that of a talent of copper, the weight of which was 1,000 times as much. The talent (*tikkar*) of the Hebrews, frequently named in the Old Testament, was a weight equal to 98 lbs. 12 oz. avoirdupois. Its subdivisions were the maneh or mina and the shekel, 100 of the latter making 1 mina and 80 minas a talent. Its value is rated at about \$1,500.

TALFOURD, SIR THOMAS NOON, an English author, born at Doxey, a suburb of the town of Stafford, Jan. 26, 1795, died in Stafford, March 18, 1854. He was the son of a brewer at Reading, and was educated at the grammar school of that town. He studied law at London under the direction of Mr. Chitty, the eminent pleader, and at the same time cultivated literature, for which even while a boy he had shown a marked talent by poetical contributions to a Reading newspaper. His taste for dramatic poetry led him to frequent the theatres, and he wrote much while yet a law student for the magazines, and occasionally served as a law reporter for the daily journals. In 1821 he was called to the bar; his steady application to his profession and fluent and graceful elocution soon gave him an extensive practice, and in 1838 he was made sergeant-at-law. In 1835 he was elected to parliament from the borough of Reading by the liberal party, and continued a member till 1841. In 1847 he was again elected, and held his seat till 1849, when he vacated it in consequence of being made a judge of the court of common pleas. As a member of parliament Talfourd was distinguished by his efforts in behalf of the rights of authors, for whose benefit he introduced in 1837 the copyright act which, somewhat modified, was passed in 1842. As an author he acquired his highest reputation by his first published work, the tragedy of "Ion," which was printed in 1835, and in the following year was acted with great success under the direction of Mr. Macready. "Ion" was followed by another tragedy on a classic subject, "The Athenian Captive," which was also successful on the stage, and by two others on modern

topics, "Glencoe" and "The Castilian." All these dramas are deficient in real dramatic character and interest, their chief merits being smooth and graceful versification, high-toned sentiment, and a profusion of elaborate imagery. Beside several sketchy volumes of travels on the continent, Talfourd published two valuable and interesting works, containing memoirs and correspondence of his intimate friend Charles Lamb. These appeared in 1837 and 1838, and are now published as one work, "The Life and Letters of Charles Lamb." He died suddenly while delivering a charge to the grand jury and commenting on the increase of crime.

TALIACOTIUS, GASPARO (TAGLIAOOZIO, or TAGLIAOOZZI), an Italian surgeon, born about 1489, died in Bologna, where he was professor of anatomy and surgery, in 1558. He attained high renown for his medical lectures during his life, but is now mainly remembered for what has been named from him the Taliacotian operation, for the restoration of lost noses, ears, &c. Though this operation was not original with him, yet he carried it to greater perfection and was more successful in restoring the lost features than any of his predecessors. His process was fully detailed in his posthumous work, *De Curatione Chirurgia per Institutionem Libri II.* (2 vols. fol., Venice, 1597). His method was to replace the nose by a piece from the arm, leaving one end attached to the arm until it had formed a vital connection with the face, when it was cut off from the arm, and fashioned by long and slow processes into the semblance of a nose. The French and Indian operations have now generally superseded that of Taliacotius. (See **AUTOPLASTY**.)

TALIAFERRO, a N. E. co. of Ga., drained by affluents of the Ogeechee and Little rivers; area, 185 sq. m.; pop. in 1860, 4,583, of whom 2,849 were slaves. The surface is hilly and the soil generally fertile. The productions in 1850 were 193,327 bushels of Indian corn, 28,690 of oats, 29,061 of sweet potatoes, and 5,170 bales of cotton. There were 7 churches, and 180 pupils attending public schools. Granite, gneiss, sulphuret of iron, and magnetic ore are found. It is intersected by the Georgia central railroad. Capital, Crawfordville.

TALIESIN, called also Pen Beirdd, the chief of the bards, flourished between 520 and 570. He was a native of Wales, and in the latter part of his life was in the service of Urien Rheged, a British prince, to whom many of his poems were addressed. Specimens of his compositions are preserved in the "Welsh Archæology."

TALIPOT TREE. See **PALM**, vol. xii. p. 702.

TALISMAN (Gr. *τελεσμα*, tribute, or Arab. *theliam*), primarily, a figure cast in metal or engraved upon stone, at a particular hour and under the influence of certain planets, whereby it was supposed to acquire extraordinary properties, and to be able to confer on its possessor supernatural powers. The name was afterward extended to any article, whether a production of nature or art, which possessed

the same qualities. The talisman differs from the amulet in the fact that the powers of the latter are passive and only preservative from harm or injury, while the talisman, if a powerful one, and prepared under a happy conjunction of planetary influences, could, it was believed, render its owner invisible, and subject to his sway the elements or the genii; enable him instantly to pass through the air or over the seas from one place to another; to strike his adversary with a deadly blow while secure from injuries himself; to win the affections of a beloved object, &c. The talisman originated in the period when astrology was in the ascendant; but though its supernatural powers are no longer credited in civilized countries, there is yet a lingering trace of the same superstition left in the charms which are supposed to bring good luck to the possessor. In savage countries, the fetich of the African and the medicine bag of the North American Indian partake more of the character of the talisman than of the amulet.

TALLADEGA, a N. E. co. of Ala., bounded W. by the Coosa river and drained by the Choccolocco and other streams; area, 1,260 sq. m.; pop. in 1860, 28,520, of whom 8,865 were slaves. The surface is moderately hilly and the soil fertile. The productions in 1850 were 715,584 bushels of Indian corn, 115,105 of sweet potatoes, 114,550 of oats, and 8,509 bales of cotton. There were 47 churches, 2 newspaper offices, and 370 pupils attending public schools. Excellent marble is found. The Alabama and Tennessee rivers railroad is finished to Talladega, the capital.

TALLAHASSEE, a city and the capital of Florida, and seat of justice for Leon co., about 180 m. E. from Pensacola; lat. 30° 28' N., long. 84° 36' W.; pop. in 1860, 1,043. It is situated on an elevated plateau, and is well built and handsomely laid out. It has 2 newspapers, several schools, and Presbyterian, Methodist, and Episcopal churches. The state house is a substantial edifice, and the other public buildings are a court house, gaol, U. S. land office, and state seminary. Tallahassee is noted for its springs of pure water and its salubrious climate. It is connected with Jacksonville on the E. coast by the line of the Pensacola and Georgia railroad, completed for 60 m., and with St. Marks on the gulf by the Tallahassee railroad, 22 m. long.

TALLAHATCHIE, a river of Mississippi, the principal tributary of the Yazoo, rising in Tipah co., near the N. line of the state, and flowing in a circuitous but generally S. W. and S. course 250 m. to its junction with the Yallahusha river to form the Yazoo. It is navigable by steamboats a distance of over 100 m., and at high water still further.

TALLAHATCHIE, a N. W. co. of Miss., intersected by the Tallahatchie and Yallahusha rivers; area, 980 sq. m.; pop. in 1860, 7,893, of whom 5,054 were slaves. The surface is level and in many places swampy, and the soil

fertile. The productions in 1850 were 190,980 bushels of Indian corn, 38,052 of sweet potatoes, and 4,977 bales of cotton. There were 8 churches, and 200 pupils attending public schools. Capital, Charleston.

TALLAPOOSA, a river of Georgia and Alabama, which rises in Paulding co., Ga., and flowing S. W., S., and W. for a distance of 250 m., unites with the Coosa, forming the Alabama, about 10 m. N. from Montgomery. Its principal affluent is the Little Tallapoosa. It is navigable for steamboats a distance of over 40 m. above its confluence with the Coosa.

TALLAPOOSA, an E. co. of Alabama, intersected by the Tallapoosa river, and drained also by the Hileebec and Sawkehatchee creeks; area, 700 sq. m.; pop. in 1860, 28,827, of whom 6,672 were slaves. The surface is hilly and the soil in some parts fertile. The productions in 1850 were 462,276 bushels of Indian corn, 60,423 of oats, 102,371 of sweet potatoes, and 6,569 bales of cotton. There were 7 grist mills, 2 cotton factories, and 24 churches. Its S. border is intersected by the Montgomery and West Point railroad. Capital, Dadeville.

TALLART, or **TALLARD**, CAMILLE DE LA BAUME, count de, a French general, born Feb. 14, 1652, died in Paris in 1728. He entered the army under Condé in Holland, and subsequently served under Turenne in Alsace, became a brigadier in 1677 and major-general in 1687, commanded an army corps on the Rhine in 1690, was raised to the rank of lieutenant-general and sent as ambassador to England in 1693, and in 1698 and 1700 signed two treaties with William III. relative to the Spanish succession. In 1708 he was made marshal of France, and gained a victory over the prince of Hesse at Spire, but was defeated and made prisoner by his own fault in the battle of Blenheim the next year. After 7 years of captivity he returned to France, and was made duke of Hostun and a peer in 1713, took sides with the Jesuit Le Tellier against Cardinal de Noailles, in 1715 became one of the council of regency, and in 1726 secretary of state.

TALLEYRAND-PÉRIGORD, CHARLES MAURICE, prince de, a French statesman, born in Paris, Jan. 18, 1754, died there, May 20, 1838. The eldest son of a family who claimed the first rank among the nobility of southern France, he was sent out to nurse and quite neglected by his parents; an accident which befell him, when scarcely a year old, rendered him lame for life. At the age of 12 he was placed by an uncle at the Harcourt college in Paris. Two years later, it being ascertained that his lameness could not be cured, a family council decided that his birthright should be transferred to his younger brother, and destined him for the church. He was consequently entered at the theological seminary of St. Sulpice; but he neglected the study of theology for literature and science. He was introduced to society in 1774 as the abbé de Périgord, and at once evinced all the propensities of a confirmed rake, so

much as to occasion his confinement for several months in the Bastille and at Vincennes. He however soon distinguished himself by refined taste and great conversational powers; and in 1780, through the influence of his family, he was appointed to the important office of general agent for the clergy of France, in which capacity he displayed remarkable business talent. He mingled in the financial discussions of the time, became acquainted with Mirabeau, Calonne, and Necker, and was noted for his prudence and skill as a speculator. In 1787 he was one of the assembly of notables, and the next year was made bishop of Autun, which gave him a yearly income of 60,000 francs, with a prospect of becoming archbishop of Rheims and a cardinal. Such was not however the aim of his ambition, as from the beginning he had looked upon his profession with a mingled feeling of disgust and contempt. When the states-general were summoned in 1789, he was elected one of the deputies of the clergy, insisted upon his colleagues joining at once the representatives of the third estate who had assumed the name of "national assembly," figured conspicuously among Mirabeau's friends, and proved a strong supporter of every liberal measure. It was he who moved the celebration of the great patriotic feast, styled the "federation," on July 14, 1790; and in his capacity of bishop, at the head of 200 priests, wearing the national colors over their white robes, he officiated in that solemnity upon the great altar erected in the midst of the Champ de Mars. In the assembly he reported a plan for the reorganization of public instruction, which plan and report are still considered masterpieces of ingenuity; he advocated the abolition of ecclesiastical tithes, the assumption by the government of the lands belonging to the clergy as national property, and the establishment of a civil constitution for that order; and on this constitution being adopted, he consecrated such priests as consented to take the oath to it. This, added to his many deficiencies as a Catholic bishop and his political course, caused him to be excommunicated by the pope. He attended Mirabeau in his last moments, and was charged by the great orator to deliver in the assembly a speech he had prepared upon testamentary powers and the rights of succession. On the adjournment of the constituent assembly, Oct. 1, 1791, Talleyrand was sent, under Chauvelin, on a mission to England to promote friendly relations between that country and France; but he was coldly and even disdainfully treated, his exertions proved fruitless, and he returned home previous to Aug. 10. After the king's fall he retired to England; but, while a warrant was issued against him in Paris by the committee of public safety (1793), he received peremptory orders from the ministry to leave England in 24 hours. He then sailed for the United States, where, through successful speculations, he accumulated a fortune, and carefully studied American institu-

tions and commerce. Before the adjournment of the convention, on motion of Chénier, acting under Mme. de Staël's influence, his name was erased from the list of emigrants; he returned to Paris, found himself a member of the academy of moral and political sciences, was one of the original members of the constitutional club, and in July, 1797, was called to the ministry of foreign affairs. On Bonaparte's return from Italy, Dec. 5, he welcomed him, introduced him to the directors, delivered a speech in his honor at his great official reception, and promoted his subsequent designs. While the young general sailed for Egypt, the diplomatist was to repair to Constantinople in order to reconcile the sultan to the invasion of one of his provinces; he however neglected this mission, and continued in office till June, 1799, when he was forced to resign, his diplomacy not having fulfilled the expectations formed of it. When Bonaparte returned from Egypt, he again propitiated the conqueror, procured an interview between Bonaparte and Sieyès, and prevailed upon Barras to resign, thus greatly contributing to the success of the *coup d'état* of the 18th Brumaire. He was rewarded by his reappointment, in Dec. 1799, as minister of foreign affairs, which office he held for nearly 8 years. His pliancy, aristocratic associations, and refined manners suited the new master of France, under whose leadership he aided in the reestablishment of the peace in Europe, taking part in the successful conclusion of the treaties of Lunéville, 1801, and of Amiens, 1803. In 1804 he was released from excommunication and his clerical vows, and, yielding to Bonaparte's injunction, took formally as his wife Mme. Grant, with whom he had lived for the last 7 years. His influence was now on the wane, or at least his advice was less complacently listened to. In 1806 he received the office of grand chamberlain and the principality of Benevento in Italy. Having vainly advocated an alliance with England, and feeling the growing coldness of the emperor, he resigned his ministerial office, Aug. 9, 1807, and received the title of vice grand elector, to which a large salary was attached. Thenceforth he was only occasionally consulted by his sovereign, but gave very free expression to his views upon great political questions, and was in consequence deprived of his office of chamberlain in 1809; but this only stimulated his sarcastic criticisms against the imperial policy. As early as 1812 he is said to have foretold the approaching overthrow of the unruly conqueror. He accordingly prepared himself for the crisis, and so skilfully manœuvred that on its occurrence he was looked upon, at home and abroad, as the most influential statesman of the day and the leader of the new revolution. A last interview between him and the emperor in the beginning of 1814, during which he was very harshly treated by Napoleon, completed the estrangement between them; and Talleyrand, although still a dignitary of the empire and one of the council

of regency, thought of nothing but ruining his master. While the latter was accomplishing wonders of skill and valor on the battle field, he secretly sent word to the allied sovereigns to hasten toward Paris; and when that metropolis surrendered, March 30, he offered his hotel to the emperor Alexander. His management secured the appointment by the senate, on April 1, of a provisional government, and its formal declaration on the following day that Napoleon was dethroned. While Marshal Marmont was prevailed upon to sign at Essonne (April 8) a convention that baffled Napoleon's last hopes of resisting, Talleyrand welcomed the count of Artois to the French metropolis, April 12, and remained the head of the new government. On the arrival of Louis XVIII. he was appointed (May 12) minister of foreign affairs, holding in fact the premiership in the cabinet; and on June 4 he was made a peer of France. He negotiated the first treaty of Paris, May 30, 1814; and 4 months later he was sent as minister plenipotentiary to the congress of Vienna, where, notwithstanding his superior abilities as a diplomatist, he failed in protecting the interests of France as well as he desired. He was overtaken there by the sudden return of Napoleon from Elba, and participated in the declaration that "outlawed the enemy of nations." He was excepted from the amnesty granted to those who had previously deserted the emperor, repaired to Ghent, where he joined the exiled king Louis XVIII., accompanied him to France when he returned there after the battle of Waterloo, and resumed, July 8, 1815, the premiership in the cabinet and the ministry of foreign affairs; but being disgusted by the hard terms imposed upon France by the allied powers and by the reactionary tendencies of the new chamber of deputies, he resigned his office at the end of a few weeks. According to another account, having become obnoxious to the emperor Alexander, he was dismissed; but through the duke of Richelieu's entreaties he received the title of grand chamberlain of France, with a salary of 40,000 francs. He still visited the Tuileries, but was coldly received; he retained his seat in the chamber of peers, and delivered there several opposition speeches; but his influence was greatest in social intercourse, his saloon being the gathering place of politicians of every shade of opinion. After the revolution of July, 1830, he was appointed ambassador to England with a princely salary, and succeeded in negotiating a treaty, April 22, 1834, by which France, England, Spain, and Portugal united for the pacification and settlement of the two peninsular kingdoms. Satisfied with this last performance, he resigned his office, Jan. 7, 1835, and retired to private life. In 1838 he delivered the eulogium on Count Reinhardt before the academy of moral and political sciences. During his latter years he returned to the observance of ecclesiastical rites, and died reconciled to the church. The most remarkable of

his essays is his *Mémoire sur les relations commerciales des États Unis vers 1797*. He left personal memoirs, which are supposed to throw considerable light upon the events in which he participated, and are to be published, according to his will, 30 years after his death, that is to say, in 1868.

TALLIEN, JEAN LAMBERT, a French revolutionist, born in Paris in 1769, died Nov. 20, 1820. He was the son of the house steward of the marquis de Bercy, who gave him the means of a classical education, and when the revolution broke out was for a while connected with the newly established *Moniteur* as proof-reader. In 1791 he started a newspaper of his own, *L'ami du citoyen*, which passed unnoticed, became a member of the Jacobin club, was appointed clerk of the commune, Aug. 10, 1792, and was elected deputy to the convention by the department of Seine-et-Oise. He took his seat among the *montagnards*, evinced some oratorical talent, voted for the death of Louis XVI., and proved one of the bitterest opponents of the Girondists. Being sent on a mission to Bordeaux in 1794, he became acquainted with Mme. de Fontenay, one of the most fascinating women of her age, then a prisoner on account of her suspected royalism, and whom he married on his return to Paris. His love for her somewhat abated his revolutionary fervor, and Bordeaux was treated with comparative mildness. This, in conjunction with his known friendship for Danton, awoke the suspicions of Robespierre; his wife was again imprisoned, and was in peril of her life, when, yielding to her entreaties, he resolved upon overthrowing the tyrant. After securing the combined assistance of Robespierre's enemies, he denounced him in a virulent speech on the 9th Thermidor, and by unfaltering energy succeeded in procuring from the convention an order of arrest against the dictator, and then bringing him to the scaffold. This triumph made him the leader of the Thermidorians; through his influence Fouquier-Tinville, Carrier, and Lebon were doomed to condign punishment; and through his energy the revolutionary attempt of the 1st Prairial was baffled. As commissary of the convention near the army of the west in 1795, he ordered all the royalist prisoners made by Hoche on the Quiberon peninsula to be shot. On the 18th Vendémiaire he was among the unterrified defenders of the convention against the rebellious sections of Paris. After the establishment of the directorial government he was a member of the council of 500, and shared in the republican *coup d'état* of the 18th Fructidor. In 1798 he sailed with Bonaparte for Egypt, as one of the committee of scientific men, and held there a high administrative office. While returning to France he was taken prisoner by the English, and welcomed to London by the whig party. When he finally reentered France, his fortune changed. Bonaparte treated him coldly and declined granting him any office;

his wife was divorced from him, afterward becoming the princess of Chimay (see CHIMAY); and he was neglected by all. In 1805 he was appointed consul to Alicante; but sickness obliged him to return to Paris, where he received a paltry pension from Napoleon. This he lost in 1814, and would have starved had he not received some help from his old friend Barras.

TALLMADGE, BENJAMIN, an American revolutionary officer, born in Setauket, Long island, Feb. 25, 1754, died in Litchfield, Conn., March 7, 1835. He was graduated at Yale college in 1773, entered the continental army at the commencement of the revolution, attained the rank of major after much active service, and was stationed at North Castle, Westchester co., N. Y., at the time of the capture of Major André, who was placed in his custody until his execution. In 1780 he planned and conducted the expedition which resulted in the taking of Fort George at Oyster Bay, and the destruction of the British stores on Long island. He held intimate relations with Washington, and retired from the army with the rank of colonel. He afterward engaged in mercantile business at Litchfield, Conn., and from 1801 to 1817 was a member of congress.

TALLMADGE, JAMES, LL.D., an American statesman, born in Stamford, Dutchess co., N. Y., Jan. 28, 1778, died in New York, Sept. 29, 1858. He was graduated at Brown university in 1798, studied law, and was admitted to the bar in New York. He was for some years private secretary of Gov. George Clinton, and in the war of 1812 was appointed brigadier-general and placed in command of a part of the force stationed for the defence of the city of New York. In 1817 he was elected to congress from Dutchess co., and was a prominent debater and actor in the stormy scenes which preceded the passage of the Missouri compromise bill, advocating the restriction of slavery in the region west of the Mississippi. He declined a reelection. In 1821 he was an active member of the state constitutional convention, in 1824 was a member of the legislature, in 1825 was elected lieutenant-governor, and in 1846 was a member of the state constitutional convention. From 1838 till his death, with the exception of two years, Mr. Tallmadge was president of the American institute. In 1835 he visited Europe. He introduced American cotton machinery into Russia, and collected there and elsewhere maps and specimens of natural products for the institute. He was one of the founders of the university of the city of New York, and received from it the honorary degree of LL.D. in 1841.

TALLOW, the fat of quadrupeds, separated from the fibrous matters by melting it down, a process called rendering or trying out. It consists of a little more than $\frac{1}{4}$ stearine, and is largely employed in the manufacture of candles and soap, the dressing of leather, &c. It is obtained of various degrees of purity according to the care with which it is prepared.

When pure it is white and tasteless and has a peculiar odor. It is an important article of commerce, the largest supplies being furnished by Russia, amounting to an average of about 186,160,000 lbs. annually, at the value of about \$15,500,000. It is brought to St. Petersburg from the interior, much of the best coming from Siberia. The cattle that furnish it are there fed the greater part of the year on dry fodder, and this is said to be the cause of the superior hardness of the Russian tallow. The largest portion of the exports are to England; the rest to Prussia, France, the Hanse towns, Turkey, &c. The computed value of the importations of tallow into England in 1858 was £3,042,881, of which £2,460,275 was of Russian tallow, and £115,710 of Australian nut-tallow. In 1860 they amounted to £4,014,280. The import from the United States into Great Britain in 1860 was 8,748,961 lbs., valued at \$901,371. The total export from the United States during the same year was 15,269,585 lbs., value \$1,598,176.—A vegetable tallow is obtained on boiling the berries and other fruits of various plants. (See TALLOW TREE.)

TALLOW TREE (*Stillingia sebifera*, Linn.), a Chinese tree belonging to the family of the *euphorbiaceae*, from 20 to 40 feet high. It has very smooth branches, and long-petioled, rhomboidal, acuminate entire leaves, of about equal length and breadth (from 2 to 4 inches), and conspicuously pointed. The sterile flowers are small and numerous; the fruit is attached to a stalk, and is about $\frac{3}{4}$ of an inch in diameter. It is cultivated in Great Britain and America in hothouses. The fatty matter is obtained from the seed vessels and seeds, which are bruised and boiled in water, when the particles of fat rise to the surface. When cold it is of about the consistence of tallow, and beautifully white. The Chinese use it for candles, combining with it either wax or the wax-like product of the *ligustrum lucidum*, in order to give it greater hardness. It burns freely, and gives a clear light. It is also used for medicinal purposes.

TALMA, FRANÇOIS JOSEPH, a French tragic actor, born in Paris, Jan. 15, 1768, died there, Oct. 19, 1826. The son of a dentist who removed to London, he passed his childhood there, and returned when 9 years old to France, where he completed his collegiate education. He early evinced a taste for the stage, and after pursuing his father's profession for 18 months he took lessons from Molé, Dugazon, and Fleury. In 1787 he appeared at the *théâtre Français* in the subordinate part of Séide in Voltaire's *Mahomet*, making a deep impression, and two years later became a partner in the association of comedians who were attached to that theatre. He at once attempted to substitute contemporary historical dresses for the fancy costumes then worn, and finally accomplished a complete reform. His first original creation was the principal part in Joseph Chénier's *Charles IX.*; and while his success steadily increased, he assiduously studied the improve-

ment of his style of acting. He listened willingly to critical observations, and sought the society of such learned men and artists as could give him thorough instruction. Among those whom he saw intimately during the revolution were Louis David, the painter, and Bonaparte, then a young and poor officer, who more than once borrowed a few louis from the more prosperous comedian. Bonaparte never forgot his kindness, and when in power treated him always with special favor. Beside the parts he performed in Lafosse's *Marius*, Racine's *Iphigénie* and *Britannicus*, and Voltaire's *Œdipe*, which he successively brought as near as possible to perfection, he won great applause in Chénier's *Henri VIII.*, and above all in Ducis' *Hamlet*, *Othello*, and *Abufar*; and under the empire he was frequently called to appear before the numerous emperors, kings, and princes whom Napoleon brought together. During the restoration, his known partiality for liberal opinions and the fallen government enhanced his popularity among the younger class of the nation, and some of his performances were political manifestations in disguise; such was especially his appearance in Jouy's *Sylla*, in which his striking resemblance to Napoleon made an unheard of sensation. Since 1796 he had devoted his undivided attention to tragedy; but in 1823 he appeared as Damville in Casimir Delavigne's comedy *L'école des civalards*, in which he proved a worthy associate of Mlle. Mars. His last and perhaps most perfect tragic creation was the part of Charles VI. in Delaville's tragedy of that name; here it was that he evinced all his powers, and above all that dignity of manner and elocution which was so true to nature, and consequently so impressive. In 1855 a statue by David d'Angers, representing Talma in his great part of Sylla, was placed in the Tuileries garden. The great actor left a very interesting pamphlet entitled *Réflexions sur l'abus et sur l'art théâtral* (8vo., 1825; reprinted in 1856). His biography has been written by Moreau, *Mémoires historiques et littéraires sur Talma* (8vo., Paris, 8d ed., 1827).

TALMUD (late Heb., study), the collective name of the Mishna and Gemara, containing the oral law and other traditions of the Jews. (See MISHNA, and HEBREW, vol. ix. p. 41.) In a limited sense the term is used of the Gemara alone. There are two Gemaras (or Talmuds), the Palestinian (*Yerushalmi*, of Jerusalem) and the Babylonian (*Babli*). The former contains comments on 39, and the latter on 36 treatises of the Mishna. The Babylonian, which is of later date, is the principal authority. The chief commentator is Rabbi Solomon ben Isaac, known under the abbreviation *Rasbi*. The best compendium of Talmudical decisions is the *Mishneh torah* of Maimonides. The editions of the Talmud, mostly in 12 folio volumes, including the most important commentaries and notes, are very numerous. One of the fullest is now (1862) in course of publication in Warsaw.

TAMA, an E. co. of Iowa, intersected by the Iowa river; area, 720 sq. m.; pop. in 1860, 5,285. The surface is undulating and the soil highly fertile and well timbered. There are a number of rich valleys along the streams. The productions in 1859 were 28,937 bushels of wheat, 258,697 of Indian corn, 10,412 of oats, 110,472 lbs. of butter, and 11,205 gallons of sorghum molasses. There is good water power for manufacturing purposes, though it is not much used yet. It is intersected by the proposed route of the Chicago, Iowa, and Nebraska railroad. Capital, Toledo.

TAMAQUA, a town of Schuylkill co., Penn., on the Little Schuylkill river, 16 m. E. N. E. from Pottsville, and 78 m. N. E. from Harrisburg; pop. in 1861, 4,919. It is situated in a rich coal and iron region, and has 8 founderies and machine shops, 6 collieries, gas and water works, a bank, a newspaper, and 9 churches, viz.: 2 Methodist, and 1 each Congregational, Episcopal, Evangelical, German Reformed, Lutheran, Presbyterian, and Roman Catholic. The Chestawissa and the Little Schuylkill railroads pass through the town.

TAMARIND TREE (*tamarindus*, from the Arabic *tamarhendi*, Indian date), a tropical exogen of the natural order *leguminosae*, having pale green pinnate leaves, the flowers with 8 yellow petals streaked with red, which are alternate with the 8 upper lobes of a calyx having 5 divisions, the middle petal cucullate and the lateral ones ovate, the stamens 9 or 10, of which 2 or 3, larger than the rest, are united at the base and bear anthers, the remainder being sterile; the fruit a hard-shelled pod (legume) supported on a footstalk, 1-celled, compressed, containing 8 to 6 seeds, which are of a somewhat square form and lie within an acid pulp. The oriental tamarind (*T. indica*, Linn.) is a handsome tree with wide-spreading branches, its wood hard, heavy, and firm, and useful as timber. Its fruit pods are large, and 6 times longer than broad; the acid pulp which they contain is dried in the sun and consumed at home, or salted or dried in copper ovens for exportation. In Africa, Arabia, and India this pulp is invaluable to travellers, both as a cooling food and in the preparation of a refreshing drink. Even the hard seeds, after parting with their astringent skins, are boiled or dried, and eaten in times of scarcity, in flavor resembling the field bean. The western tamarind (*T. occidentalis*, Linn.) is found wild in the West Indies and South America, and is to be distinguished by its pods, which are not more than 8 times longer than they are broad. It is also a large tree with spreading branches, pale green foliage, and yellow-petalled and purple-stamened flowers. A rude sort of preserve is made of its fruit, by removing the shells and packing the pulp in layers with sugar between, or by pouring boiling sirup over them, which penetrates to the bottom.—The value of tamarinds in medicinal uses is well known, their properties being nutritive, refrigerant, and laxative.

TAMARISK, the name of delicate and beautiful shrubs and herbs with polypetalous flowers, many-leaved calyx, hypogynous petals, distinct styles, and consolidated fruit. They are grouped under a distinct order of *tamariscineae* by Desvauz, other eminent botanists not entirely agreeing in respect to their alliance with other families. The species mostly cultivated in gardens is the French tamarisk (*tamaris Gallica*), a native of Spain, France, and Italy. It is a highly elegant shrub, 12 to 15 feet high, with deciduous, very narrow, and fine scaly leaves of a light green; flowers small, pale red, growing in spikes near the extremities of the branches, and so numerous as to give the appearance of panicles. When in full blossom, scarcely any other shrub can be compared with it in beauty, uniting lightness and grace with elegance. Even the bark and twigs are conspicuous for their pleasant purple or red color. The German tamarisk (*T. Germanica*) grows only about 8 feet high; its branches are more upright, very brittle, and odorous, its bark smooth and yellowish; but the spikes of flowers and the small foliage render it equally desirable. Both are readily propagated from cuttings, and grow best in a light, rich soil. All the tamarisks are exclusively confined to the northern hemisphere of the old world, extending as far as the Cape Verd islands. They were early introduced into gardens in Britain, though preferring in their native habits the sea shore or the banks of rivers and torrents. Their bark is astringent, and abundance of sulphate of soda has been noticed in its ashes. Manna is produced by an *aphis* or *coccus* which feeds upon a species growing in the East. Salt is secreted from several, and in medicine and the art of dyeing the galls found on particular species are valuable.

TAMAULIPAS (formerly New Santander), an E. state of Mexico, bounded N. by the state of Oahuila and Texas, E. by the gulf of Mexico, S. by Vera Cruz, and W. by San Luis Potosi and New Leon; area, 29,814 sq. m.; pop. 147,188. The chief towns are Victoria, the capital, and Tampico. The coast is low and sandy, and several lagoons extend along the shore, the largest being Lake del Madre, which is upward of 100 m. long, and in some places 20 m. wide. The Rio Grande del Norte forms the northern boundary line, and the other streams of greatest importance are the Fernando or Tigre, Borbon, Santander, and Tampico; the mouths of all are so much encumbered with bars that they are almost useless for navigation. In the northern part of the state the flat country extends inland for some distance from the shore, and the surface then rises into elevated plains; but in the south it is diversified by numerous mountains and fine valleys. During the hot season the climate on the coast is unhealthy, but in the elevated parts of the interior it is temperate and agreeable. A great deal of the soil is fertile, and large numbers of cattle and sheep are reared.

TAMBOURINE, an instrument of the drum species, consisting of a wooden or metal hoop, over which parchment is distended, and which is hung with a sort of bells. It is held in either hand and beaten with the knuckles of the other. Certain peculiar effects of sound are produced by rubbing the parchment briskly with the thumb. The tambourine is one of the most ancient instruments known, and, from the graceful use which can be made of it in the various movements of the body, has always been a favorite with dancers.

TAMBOV, a central government of European Russia, bounded by Vladimir, Nijni Novgorod, Penza, Saratov, Voronej, Orel, Tula, and Riazan; area, 25,542 sq. m.; pop. in 1856, 1,808,172. The surface is generally level, broken in places by low hills, and in the S. it bears a strong resemblance to a steppe, being almost devoid of trees. It is drained by the navigable rivers Moksha and Vorona, tributaries of the Oka and Don. The soil of the N. part consists principally of a light sand, and the surface is covered by extensive forests and numerous marshes. Woollen and linen cloth and iron are manufactured.—**TAMBOV**, the capital, is situated on the left bank of the Tzna at its junction with the Studenetz, 268 m. S. E. from Moscow; pop. about 20,000. It is a very ancient place, and is surrounded by a rampart.

TAMBURINI, ANTONIO, an Italian singer, born in Faenza, in the Papal States, March 28, 1800. After several years' practice in the theatre and churches of his native city, he made his public debut at Bologna in 1818, and soon rose into great celebrity in Italy, in the chief cities of which he repeatedly performed. In 1832 he first appeared in London and Paris, and thenceforth until his retirement in 1854 was one of the annual attractions at those cities during the musical season. He was, with Grisi, Rubini, and Lablache, one of the original performers in Bellini's *Puritani*, and for several seasons continued to form one of that most remarkable quartet of singers. His voice, a baritone of great power and sweetness, was shown to the best effect in the operas of Rossini, Bellini, and Donizetti, and he was also an excellent actor both in serious and buffo opera. His finest parts were Figaro and Don Giovanni.

TAMERLANE. See **TIMOUR**.

TAMPIO, or **SANTA ANA DE TAMAULIPAS**, a town of Mexico, in the state of Tamaulipas, situated on the river Panuco, 5 m. from the gulf of Mexico, and 215 m. N. N. W. from Vera Cruz; pop. about 7,000. It is tolerably well built, and contains 2 churches, a custom house, 2 hospitals, a prison, and some monuments. The harbor is not very safe.

TAN, the ground bark of trees used in tanning leather. (See **LEATHER**, and **TANNIC ACID**.) When tan has been exhausted of its tanning property, it is still useful as a material for hotbeds, supplying long continued and uniform heat as it undergoes fermentation. It is much used by gardeners for this purpose.

TANAGER, a name given to the *tanagra*, a very large division of the finch family, peculiar to America, and almost entirely confined to the southern portion of the continent, the latter containing nearly 200 of the more than 220 species described by Solater. The bill has the upper mandible notched, and is usually triangular at the base and arched; the toes are armed with strong claws, and the hind toe is long and strong. They are small and brilliant birds, the prevailing colors being orange, scarlet, and black; many have a pleasing song, and a few are remarkable for their musical powers; their flight is rapid, movements active, and habits arboreal; most unite in flocks, often in the neighborhood of human habitations, but a few are solitary; the food consists of insects, fruits, and seeds. Of the 20 genera, only a few of the common ones can be here noticed.—In the genus *pyrranga* (Vieill.) the wings are long and pointed, the 2d quill nearly as long as the 3d, which is longest; tail moderate and nearly even. One of the most richly colored of North American birds is the scarlet tanager (*P. rubra*, Vieill.), about $7\frac{1}{2}$ inches long and $11\frac{1}{4}$ in alar extent; the male in the breeding season is of a general bright carmine color, with the wings and notched tail velvety black; the female is dull yellowish green, which is also the color of the young and the other sex in autumn and winter. It enters the United States from Mexico early in April, arriving in New Jersey about the middle of May; it goes as far north inland as Lake Huron, and has been found breeding in New Brunswick and Nova Scotia; it is very sensitive to cold; its migrations are performed at night; its notes are lively, but not musical according to Wilson, resembling the syllables "chip, churr." The change from the winter to the summer plumage takes place very rapidly; it is a shy and unsocial bird, preferring the deep recesses of forests, and rarely approaching human habitations in crowded villages; the food consists of fruits and insects, especially wasps and bees. As in the sub-family generally, the nest is thin and coarsely made; the eggs are 8 to 5, dull greenish blue with brown and purple specks, and are $\frac{7}{8}$ by $\frac{4}{8}$ of an inch in size. This species is found in the eastern states as far as Missouri. The Mississippi tanager or summer red bird (*P. aestiva*, Vieill.) is $7\frac{1}{2}$ inches long and 11 in alar extent; the color is light red, brightest on the head, the back dusky, and the quills and shafts of tail feathers brown; bill light horn color, and the gape, as in others of the genus, well provided with bristles bending downward; the females olive above and reddish yellow below, as are the young males; the color is lighter and more rosy than in the scarlet tanager, and the bill is much larger. It is found in the S. Atlantic and gulf states and Guatemala, so sensitive to cold that it rarely goes further north than Massachusetts, and is not seen in the southern states after the middle of September; it is of solitary habits, preferring growths

of stunted hickories and oaks. The song is like the syllables "chicky, chucky, chuck," and is chiefly at night; the food consists of insects, especially large beetles, taken on the wing; the nest is rudely made and insecurely fastened to its supporting branch; the eggs are 4 or 5, light blue, and are incubated for 12 days by both sexes. The Louisiana tanager (*P. ludoviciana*, Bonap.) is about the same size as the last; the male is yellow, and the middle of the back, wings, and tail black; head and neck tinged with red; 3 bands of yellowish across the wings, and tertials edged with whitish; female olive green above, yellowish below, with dark brown wings and tail. It is found from Kansas to the Pacific and south to Mexico; it has a pleasing warble.—In the genus *tanagra* (Linn.) the bill is short, elevated at base, rather triangular; the wings moderate, with the 8d and 4th quills longest. There are many species, all South American, living in troops, and often committing serious depredations in orchards and gardens by destroying buds and fruits; the nest is carelessly made. The bishop tanager (*T. episcopus*, Linn.) is purplish violet, with the small wing coverts bluish white, the middle shaded with violet, the larger ashy, and the wings and tail blackish bordered with blue.—In the genus *rhamphopsis* (Vieill.) the lower mandible is dilated at the base, with a horny covering produced beyond the upper. The Brazilian tanager (*R. brasilia*, Vieill.) is a very beautiful bird, of a deep scarlet or carmine color, with brown wings and tail; bill brownish, except the base of the lower mandible, which is white.—In the genus *euphonia* (Desm.) the bill is short, broad, depressed at base, arched and keeled; wings moderate, the 1st and 2d quills longest; tail short and even. They live in small troops on the top of forest trees in tropical America, principally near rivers; they are very active and restless; there are about 30 species, the prevailing colors of which are black, blue, and yellowish. The organist tanager (*E. musica*, Desm.) is about 4 inches long, the male beautifully varied with black and orange; it is found in the West Indies, and is remarkable for the sweetness and great compass of its voice; it is very shy and difficult to obtain. The blue-headed tanager (*E. elegantissima*, Gray) is 4½ inches long; the sides of head and neck, chin, throat, and upper parts generally, are steel bluish black; top of head and semicollar behind opaque blue; beneath yellowish brown tinged with chestnut; forehead dark chestnut, margined behind with blue. It is found from northern Mexico to Guatemala, and probably in California.—In the genus *calliste* (Boie) the bill is short and slender; wings lengthened, 2d and 3d quills longest; tail short and nearly even. There are more than 80 species in the warm and damp forests of South America; they are generally seen on the tops of palm and other high trees, and are almost all richly colored. The blue-throated tanager (*C. fusca*, Boie) has the throat and crown

blue; forehead and under bill and upper back black; scarlet collar, widest on sides of neck; rest of plumage parrot green; it is about 4 inches long.

TANAÏS. See DON.

TANCRED, one of the heroes of the first crusade, born in 1078, died in Antioch in 1112. He was a son of the marquis Odo or Ottobonus and of Emma, a daughter of Tancred de Hauteville, and sister of the celebrated Robert Guiscard, duke of Apulia. He took the cross under his cousin Bohemond, son of Robert Guiscard, made over his heritage to his younger brother, and embarked in 1096 from Tarento. In the plains of Chalcedon his troops joined those of Godfrey of Bouillon, and with that leader he soon formed an acquaintance and an intimate friendship. At the siege of Nice in 1097 he distinguished himself by his daring, at the battle of Dorylaeum saved the army of the cross from total destruction, and after the taking of Nice led the advanced guard of the crusading host through the unknown and desert countries of Asia Minor. He took possession of Tarsus and Menistra, to both of which Baldwin laid claim, giving rise to a bitter quarrel; but they were not long afterward reconciled. He achieved great distinction during the long siege of Antioch; and at the storming of Jerusalem he was with his men the first to mount the walls. In the horrible scenes of carnage and rapine which followed, he alone of the Christian knights manifested any sentiments of compassion, and at the risk of his own life he saved the lives of thousands of the captured. When the sultan of Egypt marched toward Jerusalem, Tancred defeated his advanced guard, and he shared in the subsequent victory at Ascalon, Aug. 12, 1099. He afterward took Tiberias on the sea of Genesareth and beleaguered Jaffa, and was made prince of Tiberias or Galilee. Bohemond, now prince of Antioch, being taken prisoner by the Saracens, Tancred marched to his relief, and administered his government during his detention; and when the former after his release went to Europe to arm the West against the Byzantine empire, he left the defence of Antioch to Tancred. During his absence his principality was attacked on all sides, but was heroically defended by his kinsman, who reduced Artesia, besieged Tripoli in 1109, and subsequently withstood in Antioch a severe siege from the Saracens. Long and anxiously he awaited the arrival of Bohemond, but that prince died at Salerno, and the vast host he had collected was scattered. Tancred now resumed the offensive, defeated the Saracens, and forced the sultan to recross the Euphrates. This was his last work. His exploits have been celebrated, partly in prose, partly in verse, by Raoul de Caen, in *Les gestes de Tancrede*; but to the "Jerusalem Delivered" of Tasso is due the romantic interest which now belongs to his name. His love for Clorinda, described in that epic, is an invention of the poet.

TANEY, a S. W. co. of Missouri, bordering on Arkansas, and drained by White river and its affluents; area, 1,540 sq. m.; pop. in 1860, 3,576, of whom 82 were slaves. The surface is hilly and the soil fertile. The productions in 1850 were 801,116 bushels of Indian corn, 11,557 of wheat, 83,826 of oats, and 78,585 lbs. of butter. Capital, Forsyth.

TANEY, ROGER BROOKE, an American jurist, born in Calvert co., Md., March 17, 1777. He is descended from a family of English Roman Catholics which settled in Maryland about the middle of the 17th century, and received his education at Dickinson college, Penn., where he was graduated in 1795. Commencing the study of the law in Annapolis in 1796, he was admitted in 1799 to the Maryland bar, began to practise in his native county, from which he was also elected a delegate to the general assembly, and in 1801 removed to Frederic. In 1816 he was elected a state senator, and upon retiring from that office in 1822 removed to Baltimore, where he has ever since resided. In 1827 he was appointed attorney-general of Maryland, notwithstanding his political views, which were strongly democratic, were opposed to those of the governor and council; and in the summer of 1831 he was appointed by President Jackson attorney-general of the United States. Upon the dismissal of Mr. Druce from the office of secretary of the treasury, Sept. 28, 1833, on account of his refusal to remove the government deposits from the United States bank, Mr. Taney was appointed to succeed him, and immediately issued the necessary orders for the removal of the deposits to the local banks selected by him as agents of the government. The senate, which had an anti-administration majority, rejected his nomination in June, 1834, by a vote of 28 to 18. In 1835 he was nominated by President Jackson as an associate justice of the supreme court; but the senate, being still opposed to the president, postponed the subject indefinitely on the last day of the term, which was equivalent to a rejection. Upon the death of Chief Justice Marshall he was appointed by Jackson as his successor, and in March, 1836, the senate, which had meanwhile changed its political complexion, confirmed the nomination. He took his seat upon the supreme bench in Jan. 1837, and still (March, 1862) holds the office. Of the various questions before that court with which his name has been associated, that known as the "case of Dred Scott" has gained a special prominence from the important political interests which it involves. The chief justice, while concurring in the judgment of the majority of the court, that the circuit court of the United States for Missouri had no jurisdiction in the suit brought by the plaintiff in error, Dred Scott, on the ground that the latter was not a citizen of Missouri, held, that for more than a century previous to the adoption of the declaration of independence negroes, whether slaves or free, had been regarded as "beings of an inferior order, and

altogether unfit to associate with the white race either in social or political relations; and so far inferior that they had no rights which the white man was bound to respect;" that consequently such persons were not included among the "people" in the general words of that instrument, and could not in any respect be considered as citizens; that the inhibition of slavery in the territories of the United States lying north of the line of 36° 30', known as the Missouri compromise, was unconstitutional; and that Dred Scott, a negro slave, who was removed by his master from Missouri to Illinois, lost whatever freedom he may have thus acquired by being subsequently removed into the territory of Wisconsin, and by his return to the state of Missouri.

TANGENT (Lat. *tango*, to touch), in geometry, a straight line which meets or touches a curved surface without intersecting it. In trigonometry, the tangent of an arc is a perpendicular to the radius drawn from its point of meeting the arc to the secant which passes through the other extremity of this arc.

TANGIER, a town of Morocco, near the W. entrance of the strait of Gibraltar, in lat. 35° 47' N., long. 5° 48' W.; pop. estimated at 10,000. It is built on high ground overlooking a spacious bay, and presents a very striking appearance from the sea. It is surrounded by a wall and defended by several forts. There are several mosques and Jewish synagogues, and a Roman Catholic church. The harbor was once good and much frequented by foreign shipping, but it is now greatly incommoded by the ruins of the old mole. The principal trade of the place consists in supplying the British garrison of Gibraltar and the cities of Cadiz and Lisbon with cattle, fowls, fruit, &c.—Tangier (anc. *Tingis*), of which there are remains 8 m. to the S. E.) is supposed to have been founded by the Carthaginians, from whom it was taken by the Romans, and it afterward passed into the hands of the Goths and Arabs. The Portuguese took it in 1471, and ceded it to the British in 1662, who erected a mole and held the place for 23 years.

TANJORE, a district of British India, Madras presidency, bounded N. by South Arcot and Trichinopoly, E. and S. E. by the bay of Bengal, S. and S. W. by Madura, and W. by Poodoocottah and Trichinopoly; area, 2,781 sq. m.; pop. in 1851, 1,676,086. There are no harbors of any importance on the coast. The country is well watered by the Coleroon and Cavery and their numerous tributaries. The surface consists for the most part of an extensive plain of great fertility. Cotton goods are manufactured to a considerable extent, and salt is made in the neighborhood of Point Calymere. The inhabitants are nearly all Hindoos, and their castes and institutions have been more perfectly preserved than in most other parts of Hindostan.—TANJORE, the capital, is situated on a branch of the Cavery, 180 m. S. W. from Madras and 45 m. from the bay of

Bengal; pop. 80,000. It stands in a fertile plain, and consists of 2 forts and several suburbs. The greater fort is about 4 m. in circumference and the lesser about 1 m., and both are strong and well constructed. The palace, which stands in the centre of the great fort, is an ancient edifice with several high towers. The Hindoo temple in the small fort is considered the finest building of the kind in Hindostan. It is 570 feet long and 200 broad, and has a pyramidal tower 100 feet high. A colossal figure of a bull, carved in black granite, which surmounts the principal entrance, is a fine specimen of Indian art. The manufactures consist of silk, muslin, and cotton goods.

TANNAHILL, ROBERT, a Scottish poet, born in Paisley, June 3, 1774, died May 17, 1810. He was the son of a weaver, and throughout his life followed the same occupation. A volume of "Poems and Songs," published by him in 1807, became exceedingly popular; but while engaged upon a revised and enlarged edition, his health gave way, and he fell into a state of morbid despondency, greatly aggravated by the refusal of Constable to print the new work. He burned all his manuscript poems as well as those which had received revision, and finally drowned himself in a brook near Paisley. An enlarged edition of his poetical remains, with a memoir, was published in Glasgow in 1838.

TANNIO ACID, or TANNIN. The astringent principles existing in a great variety of plants which render them capable of combining with the skins of animals to form leather, of precipitating gelatine, of forming bluish black precipitates with the per-salts of iron (or if a free acid be present a dark green color), were formerly termed tannin. These substances, being found to possess acid properties, are now known as tannic acid, and various distinctive names are given to them as they are found of different chemical compositions, though agreeing in their essential properties. Thus the tannic acid derived from the gall nut is termed gallotannic acid; that of the oak, quercitannic acid; of the fustic (*morus tinctoria*), moritannic acid; of the cinchona, quinotannic acid, &c. The principal sources of tannin have been named in the article **LEATHER**, and the method of extracting it has been particularly described in the article **GALL NUT**, which is the most abundant source of it. Beside this variety, which is the same as that existing in the bark and leaves of many forest trees, fruit trees, and shrubs, and in some roots, as those of the tormentilla and bistort, there is another less known, as the tannin of the catechu and kino, which precipitates the salts of iron of a dark green instead of a blue color. Gallotannic acid when pure is a whitish, uncrystallizable, solid substance, without odor, intensely astringent to the taste; it dissolves freely in water, to a less extent in dilute alcohol, and sparingly in ether. It changes blue litmus paper to red, and expels carbonic acid from its compounds

with effervescence. Its composition, according to Strecker, is represented by the formula $O_{14}H_{12}O_{14}$. Its aqueous solution exposed to the air absorbs oxygen, and is converted into gallic acid. Beside its use in tanning, gallotannic acid is employed to produce with the salts of iron the gallotannate of iron, which is the basis of most of the writing inks. It is also employed in medicine for its astringent property, chiefly in checking hæmorrhages, as a wash for ulcers, ophthalmic affections, &c. The combinations of tannic acid with iron and with lead have been applied in the form of ointments to the dressing of ringworms, gangrenous sores, &c.

TANNING. See **LEATHER**.

TANSY (*tanacetum vulgare*, Linn.), a plant formerly cultivated for its medicinal properties, but which, escaping from gardens, has established itself by the roadsides and in waste places as a hardy and troublesome weed. It belongs to the composite order, and to that section which is known as the *corymbifera*. The roots of the tansy are perennial, the stems dying down at the end of summer; the leaves are bipinnately divided, deep green; the flower heads in dense fastigate corymbs, of a golden yellow color, and blooming in August and September. There are two varieties; one with variegated or striped leaves and seldom seen; the other, not uncommon, with double or curled leaves, and more in repute for its mildness, being employed in flavoring puddings, &c. The medical qualities of tansy are the aromatic, bitter, tonic, and anthelmintic, for which it is sometimes used in dyspepsia, intermittents, and gout, or for expelling worms. The young shoots are used by the Finns to dye cloths green. There are several other species, chiefly belonging to the East.

TANTALUM. See **COLUMBIUM**.

TANTALUS, a Greek of the mythical period, differently described as king of Argos, Corinth, Lydia, or Paphlagonia. Having given offence to the gods, he was punished in the lower world by confinement in a lake, where he was tormented with thirst, yet could not drink, for the waters always receded from his lips. Branches laden with fruit also hung over his head, and when he stretched forth his hand to take the fruit the branches withdrew. From this name the English language has acquired the verb "to tantalize."

TAOS, a N. E. co. of New Mexico, bounded N. by Colorado territory and E. by the Indian territory and Texas, and drained by the Rio Grande and Canadian rivers; area, about 18,000 sq. m.; pop. in 1860, 14,108. It is mountainous in the W., being traversed by several spurs of the Rocky mountains. The productions in 1850 were 72,049 bushels of wheat and 26,638 of Indian corn. There were 11 churches, and 40 pupils attending public schools.—Taos, the capital, is situated on the right bank of a small tributary of the Rio Grande, 52 m. N. N. E. from Santa Fé. It stands in a valley at the

foot of the first range of the Rocky mountains, and is divided into two parts by a rivulet. The inhabitants are nearly all Pueblo Indians, and are proverbial for their honesty and industry.

TAPESTRY (Gr. *τάπηξ*, a carpet), an ornamental figured cloth, made by interweaving upon a groundwork or warp of hemp or flax colored threads of worsted, silk, and sometimes gold and silver, or linen and cotton. It has been used from the earliest times for lining the walls of apartments, and sometimes for covering couches, tables, and other articles of furniture. The Greeks applied the name to coverings for the floor, mention of which is made by Homer. Such were also employed by the ancient Egyptians, made of woollen and linen and ornamented with various figures. These people, as also the Hebrews, attained great skill in ornamenting textile fabrics by embroidery. (See **EMBROIDERY**.) The ornaments were formed by colored yarns worked in by the hand, and also by the loom, and in the finer specimens of the art threads of gold were introduced; and among the eastern nations the richest fabrics were studded with rubies, emeralds, diamonds, and pearls. These were hung around the inner walls of the temples, and used for lining private apartments and for the coverings of couches. The art was early introduced into France, and when Clovis in 496 adopted the Christian religion, it is stated that not only were the churches adorned with rich tapestries, but the streets themselves were curtained with them. The aid of the loom was introduced about the 9th century, but the fabrication of tapestries with the needle continued to be the chief occupation of females during a large portion of the middle ages. Up to the 12th century the use of tapestry was limited to the adornment of churches and monasteries; but after this period it began to be adopted in the dwellings of the nobility, in imitation, it is supposed, of the customs prevailing in the East, with which the crusades had made the people of the western countries familiar. The tapestry suspended in front of the walls served not merely as a protection from the cold and dampness of the stone, but it commemorated, in the designs skilfully executed by the ladies of the family, the heroic deeds of their ancestors, and was a grateful memorial to be transmitted to successive generations. In France the workmen employed in the manufacture were originally called *sarrazins* and *sarrazinois*, indicating the origin of the art as derived from the Saracens. The finest work in the 14th and 15th centuries was produced by the Flemings, and about this period the principal manufactories in the west of Europe were at Bruges, Antwerp, Arras (whence the name arras, generally applied to tapestry in England in the middle ages), Brussels, Lille, Tournay, and Valenciennes. Florence and Venice at that time produced tapestry more rich and costly than that made in the French cities; but in the 16th century the more ornamental work with threads

of gold and silver was introduced in the celebrated manufacture of Fontainebleau. The manufacture of Gobelin tapestry established by Louis XIV. is still carried on in the greatest perfection. (See **Gobelins**.)—The working of tapestry was practised with much skill in England in the time of William the Conqueror. Mention is made of silken curtains embroidered in gold, and one of the most famous pieces of ancient tapestry is the Bayeux tapestry, worked with wool upon linen by Queen Matilda and her maidens, commemorating in its designs the conquest of England. This piece of work was 214 feet long and 20 inches wide, in 72 divisions, each with a Latin superscription. In former times it was exhibited once a year for a short period in church, and then looked up. Napoleon caused it to be exhibited in several of the French cities in 1803, and then transferred it to the municipality of Bayeux. (See **Bayeux Tapestry**.) Works of this character gradually became more common, and about the end of the reign of Henry VIII. the art of weaving tapestry is said to have been introduced into England. In the reign of James I. the manufacture was established at Mortlake in Surrey, and was sustained by the patronage of Kings James and Charles. For the earlier designs old patterns were employed, but afterward original historical and grotesque scenes were furnished in great perfection by Francis Cleya. The tapestry hangings were arranged in the houses upon hooks, so as to hang a little out from the wall, thus admitting the concealment of a person behind them. Upon special occasions tapestry hangings were forwarded from one place to another, for temporary display.—The method of weaving tapestry in what is called the *haute-lisse* or high warp, as practised in France, has been described in the article **GOBELINS**. This method is distinguished by the warp threads being arranged vertically in a frame, and by the weaver standing behind them while he conducts the work. By the other method, known as the *basse-lisse*, the warp threads are arranged horizontally, with the painting to be copied under them. The weaver, sitting in front of the frame, observes the pattern through the threads, which he occasionally parts with his fingers, and then depressing the treadles, he introduces the colored thread or worsted by means of a shuttle called a *fillette*, and drives the weft thus introduced close up with the teeth of a sort of comb. As the face of the work is on the under side and cannot be seen until the whole is finished, the other or *haute-lisse* is generally preferred. By either method the work is very slowly conducted. Tapestry is now woven in pieces of any desired breadth; but formerly the frames were so narrow that it was necessary to unite different breadths together, and this was done so skilfully that no imperfection was perceived in the design.

TAPEWORM. See **ENTROZOA**, vol. vii. p. 228.

TAPIOCA. See **CASSAVA**.

TAPIR (*tapirus*, Cuv.), a genus of pachyderm mammals, characterized by a nose prolonged into a short, movable proboscis; skin very thick and covered with close short hair, the neck furnished with a kind of stiff mane; tail very short; ears small, erect, and pig-like; 4 toes on the fore and 3 on the hind feet, separate and ending in nail-like hoofs; skull pyramidal as in the hog, with the nasal bones much arched for the muscles of the proboscis; teeth, 6 incisors and 2 small canines in each jaw, and molars 14 above and 12 below. The tapirs have nothing of the majestic appearance and sagacity of the elephant, and the proboscis can hardly be called a prehensile organ; they look more like hogs, but the legs are longer; they inhabit the moist tropical forests of South America and of the Malayan peninsula and archipelago, usually sleeping by day in retired places, and feeding at night on fruits, grasses, and other vegetable substances, though they are as omnivorous and gluttonous as the hog; like their congeners, they are fond of rolling in the mud and water, and are excellent swimmers; they are naturally of gentle disposition and easily tamed; when pursued they take to the water if possible, where they easily defend themselves with the teeth; on land they do not go by open paths, but break through the thick undergrowth of the woods by their powerful and wedge-like head, in this way escaping the larger carnivora; they have an acute sense of hearing and of sight, and are strong and tenacious of life; their flesh is eaten both in South America and Asia. The best known species is the American tapir (*T. Americanus*, Cuv.), about 6 feet long and $3\frac{1}{4}$ high, of a uniform brown color, tinged with gray on the head and chest. It is found over almost the whole extent of South America east of the Andes, and its herds sometimes do great mischief by trampling down cultivated fields; it has only one young at a birth, and in November. The *T. villosus* (Wagl.), found upon the high Andes, differs from the preceding in having much longer hair; it is but little known, and may be a mere variety caused by a colder climate and less succulent food; it was called *T. pinchaque* by Roulin, who first described it. The Asiatic tapir (*T. Malayanus*, Horsf.) is 7 or 8 feet long, with the hind parts of the body white, and the anterior and the legs black; the trunk is 7 or 8 inches long, the eyes very small, and the rounded ears bordered with white; though the largest, it is the gentlest of the genus. Fossil species are found in the tertiary formations of central Europe; the tapir appears to be connected with the swine by the extinct *palæotherium*.

TAPPAN, DAVID, D.D., an American clergyman, born at Manchester, Mass., April 21, 1753, died Aug. 21, 1808. He was graduated at Harvard college in 1771, and, after studying theology more than two years, commenced preaching, and in April, 1774, became pastor of a church in Newbury, Mass. In 1792 he

was chosen professor of divinity in Harvard college, and held that position till his death. He published during his life about 80 occasional sermons and addresses, and in 1807 two posthumous 8vo. volumes appeared, the one containing a selection from his sermons, the other a course of lectures on Jewish antiquities.

TAPPAN, HENRY PHILIP, D.D., LL.D., an American clergyman, born at Rhinebeck, N. Y., in the early part of the present century. He was graduated at Union college in 1825, and, after studying two years at the Auburn theological seminary, was for a year assistant pastor of the Reformed Dutch church in Schenectady. In 1828 he was settled as pastor of a Congregational church at Pittsfield, Mass.; in 1831 resigned on account of ill health and visited the West Indies; and on his return in 1832 was appointed professor of moral and intellectual philosophy in the university of the city of New York. In 1838 the faculty resigned in consequence of troubles in the institution, and for some years subsequently he conducted a private seminary, and devoted his leisure to the preparation of works on philosophy and education. In 1851, and again in 1853, he visited Europe. In 1852 he was recalled to the chair of philosophy in the New York university, but before entering upon its duties was elected chancellor of the university of Michigan, which post he accepted and still holds. In 1856 he was elected corresponding member of the imperial institute of France, and the same year president of the American association for the advancement of education. His principal works are: "Review of Edwards's Inquiry into the Freedom of the Will" (12mo., New York, 1839); "The Doctrine of the Will determined by an Appeal to Consciousness" (1840); "The Doctrine of the Will applied to Moral Agency and Responsibility" (1841); "Elements of Logic, together with an introductory Review of Philosophy in general, and a preliminary View of the Reason" (12mo., 1844; revised and enlarged ed., 1856); "Treatise on University Education" (1851); "A Step from the New World to the Old" (2 vols. 12mo., 1852); and a large number of addresses and orations.

TAR, a thick, black, viscid material, a product of the destructive distillation of carbonaceous substances, as wood, peat, bituminous coals, and shales. It is a commercial article, largely produced, and applied to a variety of uses. It was known to the ancient Greeks, and Dr. Clarke, who describes the method of manufacturing it in the forests of Bothnia, states that there is not the smallest difference between the processes there practised and those of ancient Greece. Along the whole coast of the gulf of Bothnia the inhabitants are very generally engaged in this occupation. They make use of the roots of the fir trees, with logs and billets of the same, which they arrange in a stack of conical shape, fitted to a cavity in the ground, generally made in the side of a bank. In the bottom of this cavity is

placed a cast iron pan from which a spout leads out through the bank. The heap is covered over with turf, and is then fired, as in making charcoal. Tar collects in the latter part of the process of charring, and runs off through the spout into barrels placed to receive it. Tar is a product where charcoal is the chief object of the process, but is seldom obtained in quantities sufficient to render it an object to collect it, except in charring the resinous woods of the pine family. In Sweden, where the business is also an important one, some peculiar methods are adopted to increase the yield of tar in wood. Trees of no value for the saw mill are partially peeled of their bark a fathom or two up from the ground, not enough to kill them, but only to check their growth. After 5 or 6 years, when cut down, the wood is found to be much richer in resinous matters which produce tar. It is noticed that the condition of the weather during the process of charring may make a difference of 15 or 20 per cent. in the yield of tar. In the United States tar is produced in almost all parts of the country where pitch pine and the *pinus australis* are found. Along the coast of the southern states, especially of North Carolina, Virginia, and Georgia, the business has been carried on upon a large scale in connection with the manufacture of turpentine, rosin, and pitch. Old trees, which have ceased to produce turpentine, and dead wood which is rich in resinous matter, are selected for the coal pits. The process does not materially differ from that already described. The product is not only sufficient for home consumption, but large quantities are annually exported. The exports of tar and pitch for the year ending June 30, 1860, were 60,623 barrels, valued at \$151,404.—In the preparation of pyroligneous acid, tar is one of the products of the destructive distillation, settling in the bottom of the tanks in which the liquids are collected. The variety known as coal tar is obtained in the same way, when bituminous matters are distilled for the production of illuminating gas or coal oils. (See GAS, and PETROLEUM.) Both wood and coal tars are complex mixtures of a variety of liquids holding solid matters in solution or suspension; thus, wood tar contains the hydrocarbons included in the term eupion, and toluole, xylol, cymole, naphthaline, &c., beside a number of oxidized compounds, including creosote, picamar, kapnomor, &c. Rosin and paraffine are found among its solid contents. When its volatile products have been driven off by distillation or boiling, the black carbonaceous residue is known as pitch. The composition of coal tar is not materially different; though, as sometimes the term is incorrectly applied to coal oils, it is then described as containing all the great variety of products derived from the destructive distillation of bituminous coal as obtained from the gas works. Coal tar, the commonly esteemed refuse product of these works, may be considered in general as consisting of from 8 to 15 per cent. of light oils, from 60 to

67 per cent. of heavy oils, and from 18 to 35 per cent. of pitch; the best coals, as the cannel and Boghead, produce tar more rich in light oils, and yield least pitch.—Wood tar is thick and hard in cold weather, and softens when warm so as to flow like thick molasses. Its specific gravity is about 1.04. It is applied to various useful purposes. It is boiled down to produce pitch, is used to coat the bottoms of vessels to render them water-tight, and to cover rigging of ships to preserve it from the action of the weather, and is a useful lubricant for the journals of wheels. In medicine it is used internally in chronic catarrhs, and in some cutaneous diseases, as ichthyosis. The inhalation of its vapor is recommended in cases of bronchial disease, the air of a room being impregnated with it by moderately heating the tar placed in a cup over a lamp. It has been found beneficial as an external application to ulcers and various diseases of the skin. It is administered in pills mixed with flour, or in an electuary of tar and sugar. It yields a portion of its properties to water with which it is stirred, and this preparation, known as tar water, is administered as a stimulant and diuretic, and is applied as a wash in chronic cutaneous affections.—Coal tar possesses an exceedingly repulsive odor, and was long considered of no value; but it has recently been found that the heavy oils obtained by its distillation may be made to furnish a variety of singular products possessing rare properties, and affording rich colors applicable to dyeing (see MAUVE), and also flavors of various essences and agreeable perfumes. (See CARBOLIC ACID, ESSENTIAL OILS, and PERFUME.) Coal tar is now in common use as a coating for iron work exposed to the weather, and is used with asphaltum and other substances to form a tight covering for roofs and the walls of vaults, &c. Its use in preparing a fuel with the dust of mineral coal is noticed in FUEL, vol. vii. p. 782.

TAR, a river of North Carolina, which rises in Person co., and flows S. E., passing Tarborough, Greenville, and Washington, and finally discharges its waters into Pamlico sound by an estuary called Pamlico river. Its length is 140 m., or including Pamlico river 180 m., and it is navigable for small steamers to Tarborough, 85 m. from the sound.

TARANTO, or TARENTO (anc. *Tarentum*), a town of S. Italy, in the province of Terra d'Otranto, situated at the N. extremity of the gulf of the same name, 44 m. W. S. W. from Brindisi; pop. about 18,000. It stands upon an island connected with the mainland by two stone bridges, is defended by a citadel, and contains many good houses and fine public edifices. The manufactures include linen and cotton goods, and gloves made from the fibres of the *pinna marina*, procured in the gulf. The purple dye of Taranto, so long celebrated, still enjoys some fame. The inner port is so choked up as to be inaccessible, while the outer one is much exposed.—Tarentum was colonized

by a body of exiles from Sparta in 708 B. C.; but of its early history little is known, though it seems to have become important in consequence of the fertility of the surrounding country and the security of the harbor, which was then the best on the coast. It subsequently became a large and powerful city, and had 14 other towns subject to it. It carried on long contests with the neighboring native tribes, the Messapians and Peucetians; and in 478 B. C. its army suffered a disastrous defeat from the former, in which so many of its nobles were killed that its government, previously an aristocracy, was thereafter democratic. It afterward became predominant in the league of the Greek cities of Italy against Dionysius of Syracuse and the Lucanians. During the Samnite wars it came into collision with Rome, which declared war against it in 281. The Tarentines, as they had frequently done in former wars, looked to Greece for aid, and called in Pyrrhus, king of Epirus (see PRÆNUS), after whose defeat and withdrawal from Italy assistance was sought from Carthage by one party, while another favored submission to Rome. The latter prevailed, and the city surrendered to the consul Papirius in 272, while a Carthaginian fleet was approaching to its relief, and thereafter continued subject to Rome. During the second Punic war the citizens betrayed it into the hands of Hannibal, who held it for more than two years, with the exception of the citadel, the Roman garrison of which he was unable to subdue. In 209 Fabius Maximus retook the city and gave it up to plunder, after putting the Carthaginian garrison to the sword. It continued to be the chief town of S. Italy, though greatly decayed, under the empire, and during the middle ages shared the fate of the other cities of Magna Græcia. The present town occupies only the site of the ancient citadel, which was originally a promontory, but was made an island by Ferdinand I. of Naples, by cutting through the low isthmus to strengthen its defences.

TARANTO, DUKE OF. See MACDONALD.

TARANTULA, or TARENTULA, a terrestrial hunting or wolf spider of S. Europe, belonging to the genus *Lycosa*, the *L. tarentula* (Latr.). It is the largest of European spiders, measuring 1½ to 2 inches in the length of the body; the color is ashy brown above, marked with gray on the thorax, and with triangular spots and curved streaks of black bordered with white on the abdomen; below saffron-colored, with a transverse black band. It received its popular name from being common in the vicinity of Taranto in S. Italy; it makes no web, wandering for prey, which it runs down with great swiftness, and hiding in holes in the ground and crevices lined with its silk; there is one spiracle on each side, one pulmonary sac, and 8 eyes; it is very active and fierce, and the females defend their eggs and young with self-sacrificing bravery. Its bite was once considered highly poisonous, producing the nervous

febrile condition called tarantism, which was supposed to be curable only by dancing to lively music until the person fell exhausted; the extraordinary accounts of travellers in relation to the bite of this spider are mere fables, though in patients thus bitten it is well to combat the terrors of the imagination by the musical remedy which the popular belief regards as effectual.—The *L. Carolinensis* (Bosc) is called tarantula in the southern states; it attains a length of 2 inches, with an extent of legs of 4; it is mouse-colored above, with white sides and whitish dots and lines on the abdomen; below blackish; legs whitish tipped with black. It makes deep excavations in the ground, which it lines with silk; the females carry their young on the back, giving them a hideous appearance, as if covered with warts; the young run off in all directions if the mother be disturbed. Its poison is active, and might cause troublesome symptoms in man if the fangs could be opened at an angle proper to pierce his skin.

TARASCON, a town of France, department of Bouches-du-Rhône, situated on the left bank of the Rhône, 10 m. N. from Arles, and 50 m. N. N. W. from Marseilles; pop. in 1856, 19,092. It is connected with Beaucaire, on the opposite side of the river, by two bridges, one of which is one of the finest suspension bridges in France. Among the public buildings is an old castle of the counts of Provence, on a rock overhanging the river, which commands the town, built in the 15th century, and now used as a prison. The church of St. Martha is a fine Gothic edifice commenced in the 15th century, with a richly sculptured entrance and a crypt which contains several remarkable tombs and a marble statue of St. Martha, who is supposed to have introduced Christianity in the neighborhood. Silk, woollen, and cotton goods are manufactured. The railroad between Avignon and Marseilles passes through the town, and there is a branch from Tarascon to Nîmes.

TARDIGRADES. See SLOTH.

TARE (*vicia sativa*, Linn.), one of the *leguminosa*, and when used as a green crop of great agricultural importance in certain districts of Europe. Its root is annual, its stem climbing, about 8 feet high; the leaflets of its pinnate leaves are oblong, and terminate abruptly in a small point; stipules small and toothed; flowers usually in pairs, sessile, red or purplish; pods more or less downy. There are several varieties, but the best are known as the winter tare, standing the severest weather unharmed, and the summer tare, which being tenderer must be sown in spring. The tare requires a clean rich soil, but will grow well in clayey land. It does not seem suited to the climate of the United States, though occurring occasionally by the roadside as an adventitious weed. The seeds are found to be nutritive, and can be used much in the same way as peas. There are several other species of tare or vetch found in the United States, having ornamental blue or purplish flowers. (See LENTIL.)

TARE AND TRET, allowances made by the seller of package goods which are sold by weight to the buyer, for the real or supposed weight of boxes, casks, bags, &c., and for the dust or refuse matter contained in some classes of goods. Tare is distinguished as real tare, or the exact weight of the box, cask, &c.; customary tare, or a fixed allowance for this weight, sometimes regulated by ordinance and sometimes by custom; and average tare, which is deduced from weighing a few packages, and taking their average as the allowance for the whole. In goods which can be unpacked without injury, the practice is to allow the real tare. The allowance of tret is a fixed one, being 4 lbs. for every 104 lbs. in goods which are liable to loss from dust, refuse, &c.

TARENTUM. See **TARANTO**.

TARGUMS (Chal. *targem*, to explain), the designation of the various Chaldee versions or paraphrases of Hebrew scriptural books, generally included in the larger rabbinical, as well as in polyglot editions of the Bible. The principal Targum is that generally, though according to most recent critics erroneously, attributed to Onkelos. (See **CHALDEE LANGUAGE**.)

TARIFA, a town of Spain, province of Andalusia, situated in the narrowest part of the strait of Gibraltar, on the southernmost point of the kingdom, in lat. 36° 8' N., long. 5° 35' W., 52 m. N. W. from Cadiz, and 25 m. S. E. from Cape Trafalgar; pop. about 12,000. It is fortified, but the walls and towers are old, and the chief defence of the place consists of a fortress upon a rocky island close to the shore. A Moorish castle stands within the walls, and is now used as a prison. There are a few manufactures.—Tarifa was named in honor of Tarif ibn Malik, a Berber chief who first landed here from Africa to reconnoitre the country; and it afterward became a frontier town of great importance. Here during the Moorish domination all vessels passing through the straits were stopped and compelled to pay duties at fixed rates; whence the word tariff in English and other languages. In 1292 Sancho el Bravo captured it, and Alonso Perez de Guzman held it against the Moors in 1294. In 1840 the Moors besieged it again, but were defeated by the kings of Castile and Portugal, and forced to retire. In 1811 it was garrisoned by 1,200 British troops and 600 Spaniards, and in December was besieged by 10,000 French troops, who were finally forced to retire with heavy loss after breaching the wall. The French captured the place in 1823 after a trifling resistance.

TARLETON, **BANNASTRE**, an officer of the English army during the American revolution, born in Liverpool, Aug. 21, 1754, died in Jan. 1838. He began the study of the law, but on the breaking out of the war in America entered the army, came to this country with Cornwallis with the rank of lieutenant-colonel, and received permission to raise a body of troops called the British legion. This was one of the

most efficient corps the British had in the South during the war, and Tarleton, by his activity, his daring, and the celerity of his movements, contributed much to the success of the British arms in that quarter. His reputation was much stained by the massacre of Col. Buford's regiment, stationed on the Waxhaw creek, on May 29, 1780, and "Tarleton's quarter" became proverbial as a synonyme for cruelty. In the following year, at the head of 1,100 men, he attacked an inferior American force near the Cowpens under Gen. Morgan, and was badly defeated. (See **COWPENS**.) He was with Cornwallis during the rest of the war, and was present at the surrender of Yorktown. After his return to England he was promoted to the rank of colonel, and was so popular that in 1790 he was sent to parliament free of expense from his native town, which he represented in 8 subsequent parliaments. In the house of commons he voted generally with the opposition, supported liberal measures, and advocated the putting the officers of the navy on an equal footing with those of the army. In 1798 he married a natural daughter of the duke of Ancaster, and in 1817 received the commission of a major-general, though he never reentered into active service. He was created a baronet, Nov. 6, 1818, and was also made a K.C.B. He published a "History of the Campaigns of 1780 and 1781 in the Southern Provinces of North America" (4to., London, 1787).

TARN, a S. department of France, in the old province of Languedoc, bounded N. and N. E. by Aveyron, S. E. by Hérault, S. by Aude, S. W. by Haute-Garonne, and N. W. by Tarn-et-Garonne; area, 2,185 sq. m.; pop. in 1862, 353,633. The S. E. part is mountainous, and the rest of the department is traversed by hills, between which there are several plains of considerable extent. The principal river is the Tarn, a tributary of the Garonne, which receives the Aveyron, Tescou, and Agout; a little way above Alby, the capital, there is a series of falls called Saut-du-Tarn. Coal, iron, lead, copper, gypsum, and porcelain and potters' clay are found. The vine is carefully cultivated, but the wines produced are of inferior quality. Woollen, cotton, and silk goods, and iron are manufactured. Capital, Albi.

TARN-ET-GARONNE, a S. department of France, in the old province of Guienne, bounded N. by Lot, E. and S. E. by Aveyron and Tarn, S. by Haute-Garonne, and S. W. and W. by Gers and Lot-et-Garonne; area, 1,405 sq. m.; pop. in 1862, 282,551. The whole department belongs to the basin of the Garonne, and the surface is generally flat, having a gradual slope to the W. The Garonne, Tarn, and Aveyron are all navigable in this department. Iron, coal, and marble are found. A large proportion of the soil is remarkably fertile. About $\frac{1}{4}$ of the department is occupied by vineyards, and about an equal extent by forests. Great attention is paid to the breeding of mules for the Spanish market. Woollen, linen, and silk

goods, cutlery, iron, and beet root sugar are manufactured. The department is intersected by many roads, and the railway between Bordeaux and Cette passes through the capital, Montauban.

TARNOW, FANNY, a German authoress, born in Gustrow, Mecklenburg-Schwerin, Dec. 17, 1788. In early life she was a governess in a noble family at Rügen, and after residing successively in Mecklenburg, St. Petersburg, and Dresden, established herself in 1828 in Weissenfels near Merseburg, Prussian Saxony, which has since been her home. Her first work, a romance entitled *Natalie*, appeared in 1804, and since that time she has been an industrious writer of imaginative literature. A selection from her works was published in 1880 in 15 vols., followed in 1840-42 by 4 vols. of her collected tales. An anonymous romance entitled "Two Years in St. Petersburg" (1838), and containing an account of the condition of Russia during the latter part of the reign of Alexander I., is attributed to her.

TARPEIA, a Roman maiden, the daughter of Spurius Tarpeius, who was governor of the citadel on the Capitoline hill when the Sabines invaded Rome. Tarpeia saw and admired the bracelets of the Sabines, and offered to betray the citadel to them for "what they wore on their left arms." She opened the gate at night, and as they passed in they threw upon her their shields, which were worn on the left arm, and crushed her. She was buried on that part of the hill thence called the Tarpeian rock.

TARQUIN. I. **LUCIUS TARQUINIUS PRISCUS** (THE ELDER), 5th king of Rome, assassinated in 578 B. C. According to the common story, he was the son of a Corinthian, and was born in Etruria, whence, instigated by his ambitious wife Tanaquil, he removed to Rome; but it is now believed that he belonged to a Latin family. He acquired the confidence of King Ancus Marcius, became guardian to his children, and upon the king's death seized or was elected to the vacant throne, 616 B. C. He destroyed the wealthy Sabine town of Apiolæ, and subdued the Latin towns of Cameria, Crustumium, Medullia, Ameriola, Ficulea, Corniculum, and Nomentum. His greatest exploit was the defeat of the Sabines, who advanced to the gates of Rome, but were driven back and at length completely overthrown upon the Anio. Some authors state also that the united 12 cities of Etruria were overcome by Tarquin and compelled to submit to his authority. In the intervals of war he built the vast sewers which drained the lower part of the city, and are still perfect; laid out the Circus Maximus, and instituted the great or Roman games; assigned the rows of shops in the forum to private citizens; and began to surround the city with a stone wall, which was finished by his successor. Under Tarquin 100 new members (the *patres minorum gentium*) were added to the senate, and the number of the vestal virgins was increased from 4 to 6. His death was

contrived by the sons of Ancus Marcius, who were fearful lest he should secure the succession to his son-in-law Servius Tullius. II. **LUCIUS TARQUINIUS SUPERBUS** (THE PROUD), the 7th and last king of Rome, son of the preceding, died in 495 B. C. In 584 he formed a conspiracy, murdered Servius Tullius, and usurped the throne without any of the forms of election or the confirmation of the senate. He immediately abolished all the privileges that had been conferred upon the plebeians by Servius, decreed the death of the senators who had supported them, took the whole administration of justice into his own hands, and put to death or exiled all persons who were obnoxious to him, whether plebeians or patricians. The vacant places in the senate were not filled up, and that body was seldom consulted. But though a tyrant, he raised Rome to great power. Under him the Latin league was joined by the Hernicians and by two Volscian towns, and Rome became the head of the confederacy. With the spoils from the wealthy city of Suessa Pometia he began the erection of the capitol. He subdued Gabii, a Latin city which refused to enter into the league, and in 510 besieged Ardea. While Tarquinius Collatinus was with the army before this city, his cousin Sextus Tarquinius, the king's son, went to his house at Collatia, and there violated his wife Lucretia. Lucretia sent to the camp at Ardea and summoned thence her father and her husband. With them came Lucius Brutus. To these 8 she told what had happened, enjoined them to avenge her, and stabbed herself with a dagger. Brutus led the way into the market place, whither the corpse was carried, summoned the people, and related the occurrence. So great was the hatred already entertained of the Tarquins and the indignation now excited, that a decree was immediately passed by which the king was deposed, and his family banished from the city. Tarquin hastened to Rome, but found the gates closed against him. Brutus repaired to Ardea, where he was received with joy, and the army renounced its allegiance to the tyrant. The deposed king took refuge at Tarquinii, and thence sent ambassadors to Rome to demand his private property. While in Rome these ambassadors conspired with some young nobles for the restoration of Tarquin, but were discovered, and with their confederates—among them two sons of Brutus—were executed, and the private property of the king was given up to plunder. Tarquin now formed an alliance with the Etruscan cities of Tarquinii and Veii, and endeavored to recover the throne by force, but was defeated near the forest of Arsis. He next obtained the assistance of Lars Porsena of Clusium, who marched against Rome with a great army. (See **PORSENA**.) Finally the whole Latin confederacy espoused the cause of Tarquin against Rome, and the contest was decided by the Roman victory in the battle of Lake Regillus, fought 498 B. C. Tarquin retired to Cumæ, and there died.

TARRAGONA, a province of Spain, in Catalonia, bounded N. by the provinces of Lerida and Barcelona, E. by the Mediterranean, S. by Castellon, and W. by Teruel; area, 1,866 sq. m.; pop. in 1857, 320,598. A great deal of the surface is mountainous, the province being traversed from N. to S. by the Prades range, which has numerous offsets that extend to the coast. The only river of importance is the Ebro. There are mines of lead, copper, silver, and manganese. The valleys are generally very fertile, and the hills are covered with forests of pine, cork, and oak. Silk, woollen, and cotton goods, &c., are extensively manufactured.—**TARRAGONA** (anc. *Tarraco*), the capital, is situated on the left bank of the Francoli, on the shore of the Mediterranean, 278 m. E. N. E. from Madrid; pop. 18,014. It consists of two parts, the high and the low, and is strongly fortified. There are in Tarragona remains of an aqueduct, an amphitheatre, and other works constructed by the Romans. The town is supposed to have been originally settled by the Phœnicians, and under the Romans it became the capital of the province of Hispania Tarraconensis, and is said to have contained 1,000,000 inhabitants. It was captured by the Goths, and in 516 was the seat of a church council. The town was destroyed by the Moors under Tarif, and remained uninhabited for 4 centuries. In the early part of the 12th century it began to be rebuilt, but did not regain its former importance. It was captured by the British in the war of succession, but they abandoned it when they got possession of Gibraltar. In 1811 the French under Suchet took it by storm.

TARRANT, a N. W. co. of Texas, intersected by the West fork of Trinity river; area, about 960 sq. m.; pop. in 1850, 664; in 1860, 6,020, including 850 slaves. The surface is undulating in part, but mostly prairie, and the soil fertile. The productions in 1850 were 66,000 bushels of Indian corn, 17,386 of potatoes, and 43,443 lbs. of butter. Capital, Birdsville.

TARRYTOWN, a village of Westchester co., N. Y., on the E. bank of the Hudson river, 27 m. by railroad from New York; pop. in 1860, 8,500. It has 6 churches, 8 academies, and a female seminary. The Hudson is here very wide, and is called Tappan Zee. Major André was captured in this neighborhood, and executed at Tappantown, on the W. side of the river.

TARSHISH, the name of an ancient commercial emporium, or, according to some critics, more than one, as the context of some of the passages of Scripture in which it is mentioned would indicate that it was W. and of others E. of Palestine. There are 25 or 30 references to it in the Scriptures. Tarsus in Cilicia, the island of Thasos in the Grecian archipelago, Tartessus in Spain, Carthage, some seaport of the British isles, and Point de Galle in Ceylon have all been urged as fulfilling certain conditions of the scriptural references. The following facts may be gleaned from the passages in which it is mentioned: It was largely engaged in com-

merce, and probably in ship building; the ships of Tarshish and their precious freights are often mentioned (Isa. ii. 16; xxiii. 1-14; lx. 9; lxvi. 19, &c.); it derived its name apparently from Tarshish, the grandson of Japheth, who, it is supposed, settled some of the Grecian isles or coasts, and it is several times spoken of as an island or seacoast (Gen. x. 4, 5; lx. 9; lxvi. 19); it had large traffic with Tyre and Sidon, especially in gold and silver, tin, iron, and lead (1 Kings x. 22; Jer. x. 9; Ezek. xxvii. 12); it is usually represented as W. of Palestine and of Tyre, and its ships are spoken of as broken by an E. wind (Ps. xlviii. 7). Yet we are told distinctly in 2 Chron. ix. 21, that "Solomon's ships went to Tarshish with the servants of Hiram; every 8 years once came the ships of Tarshish, bringing gold and silver, ivory, and apes, and peacocks;" and that Jehoshaphat joined with Ahaziah in building ships at Ezion-geber, a place on the Elanitic gulf of the Red sea, to go to Tarshish (2 Chron. xi. 36), while the corresponding passages in 1 Kings (ix. 26-28, x. 22, xxii. 49) state that Tarshish vessels were built at Ezion-geber and sent to Ophir, whence they brought "gold and silver," &c. This apparent discrepancy has been explained in 8 ways: 1, that the name "ships of Tarshish" does not necessarily imply that the ships were built at Tarshish or intended to ply between that and some other port, but designated a peculiar style of ships, either in the shape of the hull or rigging, as we now say an "East Indian," a "Baltimore clipper," &c., and that hence ships intended for a long coast voyage (to Ophir, wherever that might be) were called "ships of Tarshish" from their resemblance to the Phœnician model; 2, that the ships built at Ezion-geber (Solomon's only seaport) were taken through the canal of Sesostris (then open) into the Nile, and thence into the Mediterranean, a view which is urged by Dr. N. Davis in his work on Carthage; and 3, that there were two and possibly more places called Tarshish, the name being perhaps a generic rather than a specific one; that while one of these may have been Tartessus (which has on its side most critical authorities, among them Bochart, Michaelis, Gesenius, and Rawlinson) or Carthage, or perhaps one of the Grecian isles, the other was in the East, and most probably Point de Galle in Ceylon. This view is that of Sir J. Emerson Tennent as presented in his "Ceylon."

TARSUS, or **TARSOUS**, a city of Asiatic Turkey, in the pashalic of Adana, situated on the right bank of the Cydnus, about 10 m. from the Mediterranean; lat. 36° 56' N., long. 34° 59' E.; pop. about 8,000, but during the winter months it is much greater. It stands in a fertile plain, and the houses are interspersed by gardens and orchards, and are mostly low with flat roofs, but wall built of stone. The town is partly enclosed by an ancient wall supposed to have been erected by the caliph Haroun al Rashid; and there is an old castle said to have been built by Bajazet. Tarsus has

an ancient Christian church, several mosques, handsome caravansaries, and public baths. The land in the vicinity is remarkably fertile, and wheat, barley, and cotton are exported, together with copper and gall nuts brought from the neighboring mountains. During the summer months the climate is unhealthy, and the inhabitants migrate in large numbers to the elevated grounds in the neighborhood.—Tarsus is a place of very great antiquity, and is said to have been founded by Sardanapalus. It was the chief city of Cilicia, was taken by Alexander, and became a military post of great importance under his successors in the East. Under the Romans it was much favored by both Augustus and Hadrian, and rose to such importance as to rival Athens, Antioch, and Alexandria in wealth, learning, and science. It was adorned with many magnificent temples, a gymnasium, and a theatre. Tarsus was the birthplace of the apostle Paul, as well as of several Greek philosophers, poets, and grammarians.

TARTAGLIA, NICOLÒ, an Italian mathematician, born in Bresciana about 1490, died in Venice in 1557. He was left an orphan and very poor at the age of 6 years, but became the ablest geometer of his time. He taught mathematics at Verona and Vicenza, was appointed professor of mathematics at Brescia, and in 1534 was called to the same post in Venice. He discovered the method of solving the cubic equation containing the 1st and 3d powers of the unknown quantity, and in repeated contests with the ablest mathematicians of his time defeated them, being able to solve all their problems, while his own remained unsolved. In 1589 and 1540 Cardan, under the promise of strict secrecy, obtained from him his discovery, and afterward, in violation of his promise, published it in his *Ars Magna*. This led to a violent controversy and a public mathematical contest, in which Cardan being worsted, his townsmen raised a mob, and prevented a continuance of it. This solution is still known as Cardan's rule. Tartaglia published a treatise on gunnery, which has been translated into English; the first Italian translation of Euclid; and 7 or 8 other mathematical works, the best known of which is *Questi ed invensioni diversi* (Venice, 1550).

TARTAR (named from Tartarus, the infernal regions, according to Paracelsus, on account of its fiery heat), also called argol, the crude bitartrate of potash, precipitated from wines as they ferment, being set free as alcohol is produced, in which it is insoluble. When purified it is known as cream of tartar. Salt of tartar is a name often given to pure carbonate of potash. Soluble tartar is a compound of boracic acid, tartaric acid, and potash, used in medicine as a purgative.—Tartar is also the name of an incrustation which collects upon the teeth, and may be broken off in hard scales. Its composition, according to Berzelius, is: salivary mucus, 13.5; animal matter soluble in muriatic acid, 7.5; phosphate of lime (earthy phosphates), 7.9.

TARTAR, CREAM OF. See **CREAM OF TARTAR**.

TARTAR EMETIC, a double salt, consisting of tartrate of potash and tartrate of oxide of antimony. (See **ANTIMONY**, vol. i. p. 660.)

TARTARIO ACID, an acid compound existing in the juice of a great variety of fruits, sometimes free, but for the most part in combination with potash or lime. It is most abundant in the juice of the grape, forming with potash the bitartrate or tartar named above. It was first separated by Scheele in 1770. The composition of the ordinary form of tartaric acid is represented by the formula $2\text{HO}, \text{C}_4\text{H}_4\text{O}_6$. It is a white solid, of specific gravity 1.75, crystallizing in oblique rhombic prisms, which are sometimes colorless and transparent. It is permanent in the air, very soluble in water and in alcohol. Its aqueous solution becomes mouldy when kept for some time, and is slowly converted into acetic acid. It has a strong acid taste, which is pleasant in a weak solution, and is much used in the preparation of effervescing draughts with the bicarbonates of the alkalies. Its crystals when heated become strongly electrical. Its solutions when hot exert a powerful right-handed rotation upon a ray of polarized light, a property which distinguishes this from another isomeric form of tartaric acid, in which the rotation is to the left. The two varieties also exhibit some remarkable peculiarities in their crystallization, an account of which has been given by M. Pasteur in *Annales de chimie*, (iii.) xxiv. 442, and xxviii. 56. At a temperature of 340° tartaric acid fuses, and without losing weight changes into two metameric acids, metatartaric and isotartaric; and various other modifications are produced according to the different degrees of heat to which it is subjected. Tartaric acid is distinguished from other acids by forming a white precipitate, bitartrate of potassa, when mixed with any of the potash salts, thus separating this alkali from its combination with other acids.—Tartaric acid is prepared from the crude bitartrate of potash, of which 4 parts are added to boiling water with 1 part of chalk. An insoluble tartrate of lime is precipitated, and neutral tartrate of potash remains dissolved. This is decanted, and is further decomposed by adding an equivalent of chloride of calcium, which separates the remaining tartaric acid as tartrate of lime. The precipitates are well washed and digested at a gentle heat with sulphuric acid diluted with 8 or 10 parts of water. Sulphate of lime is formed, and the tartaric acid remains in solution. After filtering, the solution is evaporated in leaden vessels to the consistence of sirup when the acid crystallizes. The process on a large scale is somewhat different. About 1,500 lbs. of washed chalk is introduced into a wooden vessel called a generator, holding about 2,000 gallons, and is thoroughly mixed with about 500 gallons of water heated by a jet of steam and stirred by an agitator. The tartar is then introduced a little at a time, till

about 2 tons have been well intermixed. The carbonic acid from the decomposed chalk passes out by a pipe, and tartrate of lime is precipitated, the neutral tartrate of potash remaining in solution. Instead of using chloride of calcium to decompose the last, the cheaper sulphate of lime is employed in the state of paste. The solution, consisting of sulphate of potash, is drawn off into reservoirs, and the residue is several times washed with cold water. Sulphuric acid is then added to decompose the tartrate of lime, when the whole is run off into a leaden vessel having a perforated false bottom, and lined with twilled flannel. The liquid drains through, leaving the sulphate of lime, which is well washed, the water following the tartaric acid solution into the evaporating cisterns, where steam heat is applied through coils of lead pipe, care being taken that the temperature does not exceed 165°. The evaporation is sometimes advantageously conducted with the vacuum pan. When sufficiently condensed (to about 40° B.), the solution is drawn off into crystallizing vessels holding about 500 lbs. of the solution. In a few days, if the vessels are kept in a warm place, a crop of about 200 lbs. of crystals is obtained from each; but being colored, they are purified by redissolving and again crystallizing. The solution is purified by digesting it with bone black and filtering, when it is again concentrated and crystallized. When the residuary liquors yield no more crystals, chalk is added to take up the remaining acid as a tartrate of lime, and this is turned into the next repetition of the process. The use of a slight excess of sulphuric acid in decomposing the tartrate of lime insures the production of the finest crystals of tartaric acid. —Tartaric acid is chiefly used in medicines, and in dyeing and calico printing. In the latter it is employed to liberate chlorine from bleaching powders, so that it may produce white or "discharged" patterns on a colored ground. In medicine it is employed as a cheap substitute for citric acid or for lemonade, its solution sweetened with sugar making a pleasant cooling drink. Its use in effervescing draughts is described in the articles *EFFERVESCENT POWDERS* and *ROCHELLE SALT*. —The combinations of tartaric acid with bases are numerous, and are known as tartrates. Some of the most important of them are described under the heads referred to above. The acid being bibasic has a tendency to form double salts, of which 3 varieties have been distinguished: 1, those containing protoxides only; 2, those containing sesquioxides in addition, which are combined with the same proportion of acid as the protoxide; and 3, salts analogous to tartar emetic. In general the chief value of these compounds is as medicine, though several are used in calico printing and dyeing, as the tartrate of chromium and the tartrate of potash and tin. Of the medicinal tartrates, one much used as an excellent chalybeate preparation is the tartrate of the sesquioxide of iron and potash, obtained

in transparent scales of ruby red color, which dissolve readily in water. A tartrate of protoxide of iron is recommended by Dr. Ure, and is obtained by acting on clean iron filings with a solution of the acid. It is a pulverulent salt, insoluble in water, with a mild chalybeate taste.

TARTARS, or TATAHS, one of the three great nomadic races which occupy the table lands of Higher Asia. The name is used with much looseness by travellers and historians, and is often applied indiscriminately to Tartars, Turks, and Tunguses; but the researches of Rémusat, Klaproth, and Ritter have fully settled the question of the race to which the name Tartar, or more properly Tatar, belongs. The annals of China about the commencement of the 9th century speak of the Ta-ta as a nomadic nation, at that time occupying a region W. of the other Mongols (for they are of the Mongolian family) near Lake Bouir-Nor, in the basin of the upper Amoor. Their nearest neighbors were the Khitans, a people of Tungus race, who were established on the northern confines of China, and appear to have been the ancestors of the Mantchoos. In 824 they were conquered by the Khitans, and were scattered; a part submitting to the Khitans, others mingling with the eastern Mongols, but the larger portion flying to the S. W. across the desert of Gobi and occupying the fertile valleys of Yu-chan around the head waters of the northern branch of the Hoang-ho or Yellow river. Here they lived in friendship with the ruling dynasty of China up to the time when the Mantchoos conquered China and established the present dynasty in that empire, and threatened them in their new quarters, when they returned reluctantly to their former home on the upper Amoor. Their compulsory migrations had made them a warlike and savage race; and possessing vast numbers of horses, they often descended upon the peaceable Chinese, and plundered their villages. The terror which they imparted to these people led them to denominate every robber horde Ta-ta or Ta-tche, and thus other Mongol tribes, Turks, and Tunguses came to receive the same name. At the commencement of the 13th century there were 4 different tribes which the Chinese named Ta-tche, viz.: 1, the White Tartars, probably a Turkish tribe, originally from the Altai mountains, and following a leader named Ala-Kouch, one of the principal chiefs of Genghis Khan, and identified by Vogel with the Ongioud tribe of the present day; 2, the Savage Tartars, slaves of the White Tartars; 3, the Aquatic Tartars, whom Klaproth considers a Tungus tribe; and 4, the Black Tartars, the true Tartar race from whom Genghis Khan sprung. That chief is generally said to have given to the motley assemblage of tribes who followed his standard the name of Mongols, but the real name he bestowed upon them was Mog-ho (the audacious). In the new empire founded by Genghis Khan, the principal officers and his body guard alone were Tartars, while the rest of his army and people

were composed of Turks, Tunguses, and other Mongol tribes. The religion of Genghis Khan, a monotheism in many particulars analogous to Parseeism, was abandoned by his grandson Batu Khan for Lamaism. About a century later the Tartar princes and their people became nominally Mohammedans, though possessing but slight knowledge of the Koran or its precepts. After the crumbling of the empire of Genghis Khan, the various nationalities of which it was composed were called by the European nations indiscriminately Tartars, though the greater part of them were really Turks. In China the last record of them is in 1604, when they are said to have been recently expelled from that empire and to have returned to their nomad habits in the desert of Gobi.—For an account of the Tartar tongues, see TURANIAN LANGUAGES.

TARTARUS, in the Grecian mythology, a son of Æther and Gæa, and the father of the giants Typhæus and Echidna. In the *Iliad* Tartarus is a place as far below Hades as heaven is above the earth, and there by later writers the spirits of the wicked are said to be punished. By the later poets also the name is often used synonymously with Hades.

TARTARY, or TATARY, a name applied somewhat vaguely to an extensive region of central Asia, stretching from the seas of Japan and Okhotsk on the E. to the Caspian on the W.; and some geographers even extend the term so as to include a portion of eastern Europe as far W. as the river Don. Tartary in its most extended sense therefore includes Mantchooria, Mongolia, the country of the Khalkas, Soongaria, and E. Toorkistan, all subject to China; Independent Toorkistan; all the southern part of the Russian possessions in Asia; and in Europe the greater part of the Russian governments of Orenburg, Astrakhan, Ekaterinoslav, the Cossack provinces, and the Crimea, the last of which is sometimes called Little Tartary. The name Tartary, however, is generally restricted to the region bounded N. by Siberia, E. by the seas of Okhotsk and Japan, S. by China proper, Thibet, India, Afghanistan, and Persia, and W. by the Caspian sea; while it is properly applicable to the western part only of this territory, known as Toorkistan. (See TARTARS.)

TARTINI, GIUSEPPE, an Italian composer and violinist, born at Pisano, Istria, in 1692, died in Padua in 1770. He gave up law and theology to gratify his musical propensities, and soon acquired unrivalled proficiency as a violinist. He eloped with one of his pupils, a handsome young lady belonging to a noble family, and to avoid their wrath lived for some time in concealment at Assisi, but was finally forgiven. Such was the admiration elicited by his performance that he was styled the "master of nations." Among his celebrated pupils were Pagin, La Housaye, Pugnani, and above all Viotti. His most remarkable composition is his *Sonate du diable*, or "Tartini's Dream," which, as he related to Lalande the astronomer, he wrote on awakening from a dream in

which he had heard it performed by the devil in consequence of a bargain struck with him.

TASCHEREAU, JULES ANTOINE, a French publicist and bibliographer, born in Tours, Dec. 19, 1801. At an early age he went to Paris, became a contributor to newspapers and periodicals, and published a new and full edition of Molière's works with annotations (8 vols. 8vo., 1828-'4), to which he added in 1825 his valuable *Histoire de la vie et des ouvrages de Molière*; *Œuvres de Boufflers* (2 vols. 8vo., 1827); *Correspondances littéraires de Grimm et de Diderot* (15 vols. 8vo., 1829-'80); and *Histoire de la vie et des ouvrages de Corneille* (8vo., 1829; new ed., 1856). After the revolution of 1830 he was appointed secretary-general of the prefecture of the Seine and master of requests in the council of state; but dissatisfied with Louis Philippe's policy, he gave up these offices at the end of a few months. He edited, in conjunction with M. de Monmerqué, the *Historiettes de Tallemant des Réaux* (6 vols. 8vo., 1832-'4), and established the *Revue rétrospective*, a periodical in which, from 1833 to 1837, he published a series of interesting historical documents, forming 20 vols. 8vo. He was a deputy from 1838 to 1842, and sat among the opposition. After the revolution of 1848 he revived his *Revue rétrospective*. In 1851 he sided with Louis Napoleon, and after the *coup d'état* was appointed assistant administrator of the imperial library, and especially charged with compiling the catalogue, of which several volumes have been printed.

TASHKEND, a town of Independent Toorkistan, situated near the junction of two small affluents of the Sir Daria or Jaxartes, 90 m. N. W. from Khokan; pop. variously estimated from 40,000 to 100,000. It stands in a fertile plain covered with numerous gardens, is surrounded by a high wall of unburned bricks 12 m. in circuit, and is entered by 12 gates. A great part of the town consists of houses surrounded by gardens and vineyards, the walls of which are so close together that only narrow lanes are left between. The houses are principally built of mud, and have a mean appearance. The residence of the khan consists of a castle defended by walls and ditches; and there are several mosques, a bazaar, numerous colleges, and old temples. The chief manufactures consist of silk and cotton goods, iron, and gunpowder. An extensive trade is carried on by means of caravans.

TASMAN, ABEL JANSSEN, a Dutch navigator, born at Hoorn about 1600, died probably on his second voyage to New Guinea and New Holland. In 1642 he was sent by Van Diemen, governor-general of the Dutch East India company, to explore the extent of the continent of New Holland. He set sail from Batavia on Aug. 14, and on Nov. 24 discovered the island to which he gave the name of the governor-general. He subsequently discovered New Zealand, the islands of the Three Kings, the archipelago of the Friendly islands, and that

of the Feejee islands, and returned to Batavia after a voyage of 10 months. On Jan. 29, 1644, he undertook a second voyage along the coasts of New Guinea and New Holland, the details of which are unknown. He published a narrative of his first voyage, which was reprinted with the voyage of Coreal at Amsterdam in 1722.

TASMANIA, or VAN DIEMEN'S LAND, an island and British colony off the S. E. extremity of Australia, from which it is separated by Bass's strait, between lat. $40^{\circ} 45'$ and $43^{\circ} 85'$ S. and long. $144^{\circ} 50'$ and $148^{\circ} 20'$ E.; greatest length 186 m., average breadth 165 m.; area estimated at 27,000 sq. m.; pop. in 1861, 89,977. Beside Hobarton, the capital, the principal towns are Launceston and Richmond. The shores of Tasmania, more particularly upon the S. and W. sides, are bold and rocky, but on the N. there are several sandy beaches. There are many excellent harbors, the chief of which are those of Hobarton, Launceston, Macquarrie, Port Davy, and Swansea. Brune island, which lies off the S. coast, forms with the shores of the mainland D'Entrecasteaux channel and Storm bay, in both of which there are numerous anchorages. Maria island, off the E. coast, is about 12 m. long. Schouten island, about half its length, lies N. of it. The Furneaux islands are situated at the E. entrance of Bass's strait; one of them is 40 m. long, with an average breadth of 9 m., and another is 20 m. long by 5 broad. The Kent group lies N. of the Furneaux islands, and Banks's strait, which separates the latter from Tasmania, is about 10 m. wide. All these islands, beside several smaller, are dependencies of Tasmania. Lighthouses have been erected at convenient points on them. The principal rivers of Tasmania are the Derwent, upon the estuary of which, at the head of Storm bay, the capital is built, and the N. and S. Esk, the estuary of which is called the Tamar and is navigable for large vessels to Launceston. There are several lakes, the principal of which is the great Clarence lake, about 100 m. in circuit, though only 15 m. long, situated 90 m. N. W. from Hobarton.—A great deal of the interior of the country is mountainous and rugged. The principal chain has a mean height of about 2,500 feet, with several peaks of much greater altitude, and some estimated at between 7,000 and 8,000 feet. The river valleys are exceedingly fertile, and there are elevated plains toward the interior; but a great deal of the island has been very imperfectly explored. The formation of the cliffs upon the coast and the mountains in the interior is columnar basalt, but in other places sandstone, limestone, slate, and sedimentary strata are largely developed. Coal has been found in two places, but the quality is inferior. Gold, silver, copper, and lead have all been found in small quantities, and iron ore is very abundant. The climate is much colder than that of Australia, but there is a considerable difference between the temperature at Hobar-

ton on the S. and Launceston on the N. side of the island. In summer the average of the thermometer is 70° . All the grains cultivated in temperate regions succeed well in Tasmania; and vegetables and fruit are grown in great abundance. There are extensive forests, composed chiefly of the eucalyptus pine and acacia, much of the timber being of excellent quality for cabinet work and ship building. There are also large tracts of pasture land well adapted for cattle and sheep. The indigenous animals are chiefly marsupial, like those of Australia; one of them, peculiar to Tasmania, called the thylacine, Tasmanian wolf, or native tiger, is the largest of the Australasian carnivora. Whales, both black and spermæoeti, are numerous in the adjoining seas, particularly in Bass's strait, and the fishery is prosecuted with much vigor; and seals frequent the shores and the islands in their vicinity. The fish found in the inlets and bays upon the coast are of excellent quality, and oysters are particularly abundant. All the domestic animals of Europe have been introduced, and thrive remarkably well.—The aboriginal inhabitants are almost extinct. In physical character they closely resemble those of Australia, the greatest difference being in the hair, which is woolly in the Tasmanian, while it is straight or curly in the Australian. When the colonization of Tasmania commenced, the native population was estimated at 3,000 or 4,000; and at that time the aborigines were perfectly inoffensive. But the colonists being male convicts, and no proper discipline being enforced, the natives were so aggravated by abuse that they retaliated, and a war of extermination arose. In 1849 there were only 12 men, 23 women, and 1 child remaining of unmixed blood, who were settled in comfortable dwellings near Hobarton; and in 1859 there were remaining only 5 old men and 9 old women.—In 1848 nearly a third of the population were or had been convicts; and though transportation to the island has ceased, the moral effects must long continue to be felt. Agriculture has made considerable progress. The Tasmanian wheat is of very superior quality, and 45 bushels to the acre is considered an average crop. Potatoes are cultivated largely, and exported to Australia. The principal exports are wool, whale oil and bone, provisions, different sorts of bark, and kangaroo skins. There is an excellent road 185 m. long crossing the island between Hobarton and Launceston; and steamers sail daily between the latter place and Melbourne, and at longer intervals from Hobarton to both Melbourne and Sydney. There are numerous schools both public and private. A bishop of Tasmania was appointed in 1842, whose diocese includes the island and its dependencies. There are newspapers published at the capital and Launceston. The constitution and laws are similar to those of New South Wales and the other colonies of Australia.—Tasmania was discovered by the Dutch navigator Abel Janssen Tasman in 1642,

who named it Van Diemen's Land, in honor of the Dutch governor of the East Indies. Its discoverer supposed it to form a part of the mainland of Australia, as did also Cook, its next visitor, who coasted along part of its shore in 1769. Bass, in 1797, was the first to discover its separation from Australia by the strait that bears his name. The year following the island was circumnavigated by Bass and Flinders. In 1803 a detachment of soldiers with a number of convicts were sent from Sydney to take possession of the island. They formed a settlement on the E. bank of the Derwent, and in the following year Col. Collins arrived and removed the establishment to the opposite side of the river, and named the place Hobart Town (now Hobart), in compliment to Lord Hobart, at that time the British secretary for the colonies. The same year another establishment was formed on the W. bank of the Tamar. The ports of Van Diemen's Land were first opened to foreign vessels in 1818; and the first free emigrants arrived in the colony in 1819. In 1824 Van Diemen's Land was separated from New South Wales and became an independent colony. In 1851 convict transportation to this island was abolished, and the name was officially changed to Tasmania.

TASSO, BERNARDO, an Italian poet, born in Bergamo in 1493, died in Ostiglia in 1569. Having early lost his father, he was brought up by his uncle the bishop of Recanati, and after 1520 lived for several years in various cities of upper Italy. In 1525 Guido Rangone, general of the pope, took him into his service as secretary. In 1531 he became attached to Ferrante San Severino, prince of Salerno, followed him in the expedition undertaken by Charles V. against Tunis in 1534, was sent in 1537 to Spain on public business, and after returning to Naples married a young and beautiful heiress, with whom he retired to Sorrento. The prince of Salerno having, in consequence of political troubles, been declared a rebel and his estates confiscated, Tasso shared in his misfortunes, and during the remainder of his life was forced to travel from one court to another, his services ill rewarded, and forcibly separated from his wife, whom he tenderly loved. He passed to the court of the duke of Urbino, and afterward to that of the duke of Mantua, who made him governor of Ostiglia. Bernardo was the most prominent poet of his time, yet his name has been almost forgotten in the superior glory of his son. His greatest work is a heroic romance entitled *L'Amadigi*, founded on the story of Amadis de Gaul. It was written about 1540, published in 1560, and contains 100 cantos. One of the episodes detached from the main poem was expanded into a poem called *Floridante*, published after his death by his son. He wrote a large number of sonnets, odes, hymns, and lyrics, and much of his minor poetry is exceedingly beautiful. There are also a "Discourse on Poetry" and "Three Books of Letters" written by him.

TASSO, TORQUATO, an Italian poet, son of the preceding, born in Sorrento, March 11, 1544, died in the monastery of St. Onofrio near Rome, April 25, 1595. On his father's departure he remained with his mother, and was sent to the Jesuit school of Naples, where he applied himself with great avidity to the study of Latin, Greek, rhetoric, and poetry. In 1554 his father returned to Rome, whither Torquato was summoned, and where he pursued his studies until 1556, in which year the Spanish troops under the duke of Alva marched into the Campagna, and for safety he was sent to Bergamo. In 1557, rejoining his father at Pesaro, he attracted the favor of the duke of Urbino, who had him educated along with his own son. In May, 1559, he went to Venice, and while in that city devoted himself to the study of Dante and Petrarch, and there also imbibed that emulation of Ariosto which he says would not suffer him to sleep. His father chose for him the profession of law, and in 1560 sent him to the university of Padua, where at the end of 10 months he produced the epic poem of "Rinaldo." The news of Torquato's act was gently broken to his father, who after reading the manuscript no longer thought of opposing his son's inclinations, and with his consent the work was published at Venice in 1562. It was received throughout Italy with great favor, and its young author of 17 was everywhere called by the name of Tassino, the dear little Tasso. He now gave up the study of the law, and applied himself to poetry and philosophy. In 1569 he removed to the university of Bologna, and there conceived the idea of writing an epic poem on the crusades. Having been accused of writing satirical verses on several scholars, he was arrested and tried; and though acquitted, he resented his treatment so highly that he soon left that city. While at Correggio on the way to join his father, he received and accepted an invitation from Scipione Gonzaga to return to Padua, and become a member of the *accademia degli eterici*, which had just been founded. Here he resumed his old studies, and as a kind of preparation for his great work, he wrote his three celebrated discourses on epic poetry, which were not published until 1572. Here also he began the *Gerusalemme liberata*. Learning that the cardinal Luigi d'Este would receive him among his attendants, he went, in Oct. 1565, to Ferrara, renowned throughout Europe for the magnificence of its ducal court, and at that time more than usually brilliant with the preparations for the marriage of Alfonso d'Este with the archduchess Barbara of Austria, daughter of the emperor Ferdinand I. The departure of the cardinal for Rome on the death of Pius V. left him at liberty to follow his own inclinations, and he now made the acquaintance of the two princesses, who were destined to have so important an influence on his after life. Lucrezia d'Este was at that time 31 years old, and her sister Eleonora one year

younger; but both were extremely beautiful in person, and possessed of cultivated minds. With them he soon became a favorite, and by them was made acquainted with their brother Duke Alfonso, and was admitted to his table along with the noblest courtiers. About this time he also paid court to one of the reigning beauties of Ferrara, named Lucrezia Bendedio, and on her account defended in the academy against all disputants, in the manner of the age, 50 amatory theses, with great ingenuity and ability. In Sept. 1569, he was called to the deathbed of his father, which was followed by a dangerous illness of his own. In the spring of 1570 Lucrezia d'Este was married to the duke of Urbino, and Tasso from this time, thrown more freely and constantly into the society of Eleonora, began to manifest his passion in strains which, however guarded, could not hide the character of his feelings. In the episode of Olindo and Sofronia, interwoven with the main story of the "Jerusalem Delivered," it was not hard to recognize the portraits of Eleonora and the devoted lover who feared much, hoped little, and presumed on nothing. In 1570 he followed his patron the cardinal to France, and was received with much distinction at the court of Charles IX., but lost the favor of the cardinal; and as his haughty spirit was ill calculated to brook neglect and displeasure, he abruptly returned to Rome, and there made application to the princess Eleonora and her sister to be received into the service of Alfonso. This was easily effected, and for the performance of merely nominal duties he received a pension of 15 crowns of gold a month. In the intervals of time spent in perfecting his great epic, he composed in two months his pastoral drama of *Aminta*, which was represented in 1573 at Ferrara with great magnificence. It was received throughout Italy with unbounded enthusiasm, and for several years after it was published scarcely any thing but pastoral dramas was written in that country. In 1573 he visited Pesaro at the request of the duchess of Urbino, and on his return began the tragedy of *Torrismondo*; but at the same time laboring constantly on the epic, he at length finished it in 1573. Now began those calamities which never afterward ceased to haunt his footsteps. His situation at court had for some time been made unpleasant by the intrigues and calumnies of enemies; and he determined to leave Ferrara as soon as his poem was published, sending it in the mean while to Rome to be revised by some of his friends. These critics, who judged poetry not by any rules of taste, but by mutilated quotations from Aristotle, imperfectly understood and absurdly misapplied, inflicted constant torture upon the poet by their frivolous and often contradictory objections, and by the delay of publication thus caused. Being permitted by Alfonso to make a visit to Rome, while there he received overtures to enter the service of the cardinal Ferdinand de' Medici, afterward

grand duke of Tuscany, between whose house and that of Este there was a bitter enmity. Although Tasso did not accept of the offer, his consideration of it exposed him to the charge of ingratitude, and has been thought by some to have been the cause of the outrage and wrong he afterward suffered; but on his return in 1576 he was received with the same favor as of old at the court. Anxious for a pretext to leave Ferrara, he applied for the office of historiographer of the house of Este, made vacant by the death of Pigna; but, contrary to his expectations and greatly to his chagrin, his request was granted. His poem now also underwent a second and more merciless revision by ecclesiastics, who, in a poem treating of a subject so sacred, objected to the introduction of any thing relating to love or enchantment; and in order to gain any profit from his work Tasso was obliged to submit to the mutilation of these passages. In addition to the pain his quick sensibilities suffered by the revision of his poem, he found about this time that the chest in which his private papers were kept had been opened by one of the courtiers, who, Manso suspects, set in circulation the story of Tasso's secret love for Eleonora. Meeting him in the courtyard, an altercation ensued, in which the poet struck his opponent, who at that time did not resent the blow, but, having collected his brothers, attacked him shortly afterward from behind. Cowardice was not a fault of Tasso, who defended himself so vigorously as to put all the ruffians to flight. The circumstance caused him trouble, however, and his disquiet was much increased by hearing that surreptitious copies of his poem were printing in various cities of Italy. This threatened not only his pecuniary prospects, but his fame, as none but mutilated editions would necessarily be published. Although an order was procured from the pope to seize all printed copies, and to insist upon the restoration of those which had been sold, it did not suffice to remove his melancholy. He was tormented with the suspicion of the conduct of Alfonso's courtiers, apparently with too much reason, and fancied that he had been accused of heresy to the inquisition. At length, one evening in June, 1577, he is said to have run with his drawn dagger at one of the servants in the chamber of the duchess of Urbino, and in consequence was confined to his rooms by order of the duke. In regard to heresy he was examined by the inquisitor of Ferrara, who assured him that he was a good and faithful Catholic, and freely absolved him from all accusation. The duke now forbade him writing either to himself or to the duchess of Urbino; and on the night of June 20, 1577, Tasso fled from Ferrara, leaving behind him his books and manuscripts. He made his way through by-roads and lonely paths to Sorrento, where his widowed sister, whom Tasso had not met since he was a child, resided with her two children; and for nearly a year he lived happily with her in retirement.

Under the charming sky of Sorrento his health rapidly returned, and the desire of revisiting Ferrara took possession of him. To the duke and the two princesses he wrote letters entreating to be restored to favor; but no reply was returned except by Eleonora, whose answer gave no hope of success. He then went to Rome, and continued his solicitations; and an ungracious permission was finally accorded, but he was told that he must recognize the melancholy humor under which he was suffering, and allow himself to be cured by his physicians. He acceded to every thing, and returned; but his writings were retained, and he himself was treated with indignity, till at last, with hopes baffled and expectations disappointed, he a second time quitted Ferrara. After wandering from city to city, and being obliged, in order to supply his necessities, to sell the gold collar and ruby rings which had been given him in former years by the princess Lucrezia, he finally went to the court of Urbino, where he found for a time a quiet refuge; and in a letter describing his condition he uses the expression of Themistocles, that he would have been undone if he had not been ruined. But soon, suspecting danger, he suddenly left Urbino to go to the court of the duke of Savoy. At Turin he was hospitably received at the palace of the marquis Filippo d'Este, and by him introduced to Duke Charles Emanuel. Here he might have lived in security and honor; but his poem and his heart were both in Ferrara. On occasion of Alfonso's marriage with the daughter of the duke of Mantua, he set out against the advice of all his friends for the Ferrarese court, where he arrived in March, 1579, on the day before the expected coming of the new consort. No one welcomed Tasso, no one noticed him; the courtiers treated him with neglect, the servants with insolence; the duke would not see him, nor allow him to be admitted to the presence of the princesses; and his manuscripts were not given up. At last, outraged and indignant, he broke forth into bitter expressions against the duke, exclaiming that both he and his courtiers were a mean and worthless crew of thieves and ungrateful wretches. Orders were immediately given that the poet should be taken to the hospital of St Anna, where he was placed under strict guard, and treated as a pauper and a madman. This unexpected and terrible blow threw Tasso for several days into a state of stupor; and even when he recovered, the prospect of perpetual imprisonment among the hideous sights and sounds of a madhouse threatened to unsettle his mind. To the duke and the princesses he appealed for release in two beautiful poems; but the former would not and the latter could not help him. The intercessions of the emperor Rudolph, of the cardinal Albert of Austria, and of the duke of Mantua were of no avail; to all their entreaties the duke replied that it was only his intention to benefit and cure Tasso. The unhappy poet, condemned to a seemingly hopeless captivity, began to feel

his mind give way. From this state he partially recovered toward the end of 1580; but about the same time his feelings were again wounded by the publication at Venice of a pirated copy of 10 cantos of the "Jerusalem Delivered" in a mutilated state. It was to no purpose that he protested against this outrage, which deprived him of all hope of profit from his works; and turning to other pursuits to drown the thoughts of his misfortune, he wrote the "Dialogue of the Father of a Family," and made a collection of his later fugitive poems, which he dedicated to the two princesses. On Feb. 10, 1581, Eleonora died, in the 44th year of her age. Her death affected him deeply, but he made no public expression of his sorrow. Of the numerous elegies commemorating her virtues, not one was written by him. In the mean while 7 editions of his poem were published the first year, and all Italy was full of his praise. Fortunes were made by others out of the work, while the poet himself languished in prison; yet indirectly it was of benefit, as it established his fame more firmly, and caused him to be treated with less rigor; and his cell became a centre of attraction to men and women from all parts of Europe. In 1582 his *Romi* was published under the editorial supervision of Guarini. A literary controversy carried on at this period between the *accademia della crusca* and Tasso and his friends in defence of his epic resulted to the advantage of the latter, although it was the means of bringing the former into notice. But both the physical and intellectual nature of the poet now began to give way. Strange apparitions appeared to his sight, glittering lights danced before his eyes, hideous noises rang in his ears, and distressing visions disturbed his sleep. His debility finally culminated in a fever of so serious a nature that the physicians despaired of his life, and the duke of Mantua now succeeded in gaining his release on condition that Alfonso should be secured from all reprisal. In July, 1586, the poet went out of the gates of St. Anna, after a captivity of over 7 years. The reason for his imprisonment has never been known, and has been a source of perplexity to all the biographers and historians. Faustini ascribes it to the duke's desire to cure him of a fistula; Serassi to the angry words spoken by the poet on his last return to Ferrara; and Muratori declares that Tasso was flighty, not mad, and cannot divine the grounds of Alfonso's severity. These three were pensioned officers of the house of Este. Manso, Tasso's intimate friend, does not know the cause; Ginguené attributes the imprisonment to the previous attempt of the poet to abandon the service of the house of Este for that of the Medici; Black, the English biographer, ascribes it to insanity; and Tiraboschi, late librarian of Modena, denies altogether the rigid confinement, and thanks Alfonso for consulting "the honor, health, and advantage of Tasso in his retreat, who evinced his continual ob-

stinacy by considering himself a prisoner." There is moreover an ominous erasure in all of the poet's manuscripts or copies of his manuscripts which refer to this subject. In 1832 Rosini, professor of belles-lettres in the university of Pisa, who superintended the best and most complete edition of Tasso's works, published an essay entitled *Saggio sugli amori di Torquato Tasso, e sulle cause della sua prigionia*, in which he attempted to prove, principally from the poet's own sonnets and letters, that Tasso was a favored lover of Eleonora; that to prevent the scandal which would naturally follow, he was ordered by Alfonso to pretend madness; and that when he broke all terms with the house of Este he was imprisoned. Rosini ably maintained his ground against the attacks of the partisans of the Este family, then ruling at Modena; but the question yet remains to be definitely settled. After his release, Tasso first went to the court of Mantua, and here finished in 1596 his tragedy of "Torrismondo, King of the Goths." In Naples, where he spent much of his time, he made the acquaintance of Manso, his future biographer. Everywhere throughout Italy he was held in the highest honor. A singular and striking instance of this occurred in 1592, when the company with which he was travelling from Naples to Rome stopped at Mola di Gaeta from dread of Marco di Sciarra, a bandit chieftain. As soon as the latter heard that Tasso was at Mola, he sent him his compliments, offering him a free passage and protection on the way, and assuring him that he and his followers would be proud to execute his orders. The poet declined the offer on the ground of the indelicacy of leaving his companions; whereupon Sciarra sent word that on his account he would leave the way open for himself and his friends, and the journey was accordingly made in safety. In 1598 his *Gerusalemme conquistata*, finished the year previous, was published at Rome. Though highly successful, it never rivalled the reputation of the "Jerusalem Delivered;" but Tasso always obstinately preferred this second creation of his genius to his first, and subsequently wrote the *Giudizio* ("Judgment"), to correct the taste of those who deemed the latter superior. In 1594 he was invited to Rome to receive in the capitol the laurel crown, and on Nov. 10 arrived in that city. On account of the storminess of the season, the ceremony, which was intended to surpass all former pageants, was deferred until spring. In spite of his failing health he completed during the ensuing winter his poem in blank verse entitled *Il mondo creato*, or "The Seven Days of Creation." Tasso had felt for some time that his end was drawing nigh, and in April, 1596, he was removed at his own desire to the convent of St. Onofrio. There he was seized with a violent fever, and was informed that his last hour had come. He manifested no alarm, but thanked the physician for tidings so agreeable, and returned

thanks to Heaven that after a life so tempestuous he had been brought to a calm haven. The pope granted him the unusual favor of a plenary indulgence, and Tasso said that "this was the chariot upon which he hoped to go crowned, not with laurel as a poet into the capitol, but with glory as a saint to heaven." He refused to make a will, as he said he had very little to leave; and would not dictate his epitaph, as a plain stone would be sufficient to cover him. Of his friend the cardinal Cinthio Aldobrandini he earnestly begged that he would collect all the copies of his works and burn them; and the last hours of the dying man were not disturbed by a refusal to do that which was impossible. He was buried in the church of St. Onofrio, and about 18 years afterward an elegant monument was raised to his memory by the cardinal Bonifacio Berilacqua.—The *Gerusalemme liberata* is the great epic of modern Europe. Its subject is the last campaign, under Godfrey of Bouillon, of the first crusade (1099), and its principal personages are the Christian knights Godfrey, Tancred, and Rinaldo, the female warrior Clorinda, the gentle Erminia, and the beautiful sorceress Armida. The unity of action is perfect, yet the incidents are varied and the scenes and images are almost constantly changing. The diction is graceful, and there is perhaps no other poem except the *Æneid* which has so few weak or tedious pages. Many instances of the false taste of the time are apparent; the supernatural machinery is too prominent; and the prevailing influence of love over the actions of the heroes has given a soft voluptuous tinge to the whole poem, which, however charming to the reader, is little in accordance with the true character of the stormy incidents and fiery knights whom the poet has attempted to portray.—The life of Tasso was early written by Manso, and forms the last volume of Rosini's edition of his works (33 vols. 8vo., Pisa, 1821-'32). Another life, written by Serassi (Rome, 1785), a partisan of the house of Este, has been followed in great measure by Black, the English biographer (3 vols. 4to., Edinburgh, 1810), especially in the denial of the story of his love for Eleonora. This was not only affirmed by Manso, but was generally believed at the time; and as early as 1593 J. Eliot in his *Orthospeia Gallica* said quaintly of Tasso: "This youth fell mad for the love of an Italian lass, descended of a great house, when I was in Italy." The subject is fully treated in "The Love and Madness of Tasso," by R. H. Wilde (2 vols., New York, 1841). There have been English translations of Tasso by Fairfax, Hooker, Broadhead, Hunt, and Wiffen. All his writings have not yet been published, but some hitherto unedited appeared at Lucca in 1837-'8 under the title of *Manuscripto inedito*.

TASSONI, ALESSANDRO, an Italian critic and poet, born in Modena in 1565, died there in 1635. He studied law, in 1597 went to Rome and became the secretary of Cardinal Ascanio Colonna, and published in 1609 his *Consiglio*

razioni sopra il Petrarca, in which he subjected that poet to severe criticism. In 1612 he published his *Pensieri diversi*. In 1632 he was made councillor to Duke Francis I. of Este, and spent the remainder of his life at Modena. The work by which he is generally known is his mock-heroic poem *La secchia rapita*, "The Rape of the Bucket," which describes one of the petty wars waged between Modena and Bologna, when the soldiers of the former city had carried off a bucket from within one of the gates of the latter. His life has been written by Gironi and Muratori, and a selection from his letters was published at Venice in 1827.

TASTE, in philosophy. See *ÆSTHETICS*, and *BEAUTY*.

TASTE, the sense by which we distinguish the sapid properties of bodies, through the sensory apparatus situated in the mouth. Though the tongue takes the principal cognizance of gustatory sensations, the soft palate and its arches and the fauces share in this office; the papillary apparatus will be noticed under *TONGUE*. The nerves of taste are the lingual branch of the trifacial or 5th pair of cerebral nerves, distributed to the upper surface and front of the tongue, and the glossopharyngeal, which supplies the edges and lower surface; the latter is also regarded as the nerve by which disagreeable impressions, producing nausea and vomiting, are propagated to the medulla oblongata. These so called nerves of taste minister also to common sensation, and are excited to pain when their trunks are pressed, in which they differ from the olfactory, optic, and auditory, or the true nerves of special sense. Taste is impaired but not annihilated by section of either of these nerves, from the more or less complete destruction of the general sensation of the mucous membrane, just as division of the 5th pair affects the sensibility, secretions, and nutrition of the Schneiderian nasal membrane, with a consequent impairment of the sense of smell. A collection of vesicular matter imbedded in the medulla oblongata, regarded by Stilling as the nucleus of the glossopharyngeal nerve, and to which a part of the sensory root of the 5th pair may be traced, is considered by Carpenter as representing the gustatory ganglion. Admitting that many sensations received through the tongue (for instance, the pungent) are modifications of touch, and that many more are perceived by the nose, the general opinion of physiologists is that there are others, not appreciable to the touch or smell (like the bitter of quinine, the sweet of sugar, &c.), which are recognized only by true nerves of taste; but further investigation is necessary to show that even these last are not appreciated by the sense of touch rendered acute for this purpose. As in the case of touch, actual contact of the object with the sensitive surface is necessary, and the papillary apparatus of the tongue is essentially the same in structure as that of the skin. Sapid substances must be in solution, and at a tempera-

ture not far above or below that of the body; conditions perfectly compatible with taste (excepting what is not smell) being only a modified touch. As in touch in the blind man's fingers, taste may be educated from necessity or habit, as in the wine and tea tasters, and in epicureans. Impressions on the tongue remain for a longer time than is the case with the eye, ear, and nose; the previous taking of a powerful aromatic renders easy the administration of disagreeable medicines. The sense of taste is always placed at the entrance of the alimentary canal, and its object is evidently to direct us in the choice of food, to minister to the pleasure of eating, and to excite the flow of saliva and other fluids necessary to prepare the food for digestion; as a general rule, substances agreeable to the taste are wholesome and nutritious, and *vice versa*, though there are many remarkable exceptions. Taste is often greatly depraved from habit and in disease; in many morbid conditions its promptings indicate a necessity of the system, and they should never thoughtlessly be disregarded. Of the share which belongs to the sense of smell in what is generally called taste, any one can easily convince himself by holding the nose so as to prevent the entrance of air while sapid substances are eaten; this simple experiment will surprise any one who makes it for the first time, and show him that the tongue does not perceive the flavor of bodies in the least degree; the dulness of taste in a common cold in the head, which must have been experienced by everybody, is a fact explicable in the same manner. Disease also affords remarkable proofs that taste is a compound sense, made up of a modification of touch and of smell. The common sensibility of the tongue enables us to perceive many qualities of bodies which, singly or combined, and acting on an organ highly acute naturally or by education, may produce impressions easily mistaken for those of taste proper, which perceives the flavor of substances; thus, heat and cold, consistency, form, size, chemical and mechanical actions, are perceived by the common touch of the tongue. We must admit peculiar modifications of common touch in the ends of the human fingers, in the sensitive flying membrane of the bat, and in the portions of the skin most susceptible to tickling, without any special nerves; there is no more difficulty in admitting that the tongue may be the seat of a similar modification of common touch, and that the only special nerve concerned in taste is the olfactory. Animals distinguish by the nose principally, and man by his tongue, the qualities of food fit for them, but both through the sense of smell. In this view of the sense of taste, there is no difficulty in understanding why the human tongue should be supplied by both lingual and glossopharyngeal nerves; man, savage and civilized, is liable to eat many injurious substances whose flavor, &c., may be agreeable; the lingual nerve therefore is espe-

cially acute for the rejection of substances improper in temperature, consistency, and chemical or irritating qualities; the glossopharyngeal guards the entrance to the œsophagus, and by reflex action causes the expulsion by vomiting of any thing improper which the lingual and even the olfactory may have allowed to pass. It may also be remarked that physiology furnishes no other instance of the double function of branches of a single nerve implied in the usual doctrine of common and special sense in the lingual and glossopharyngeal nerves.

TATE, NAHUM, an English poet, born in Dublin in 1652, died in Southwark, Aug. 12, 1715. He was educated at the university of his native city, and went to London, where he became involved in pecuniary difficulties from which he was relieved by the earl of Dorset. After the death of Shadwell in 1692, Tate succeeded him as poet laureate. His birthday ode for George I. is considered the least miserable of his laureate productions. He died in the precincts of the mint, at that time a privileged place for debtors, and during his latter years seems to have been intemperate. He was associated with Dryden in the authorship of "Absalom and Achitophel," the 2d part of which is mostly his composition. He wrote "Memorials for the Learned, collected out of eminent Authors in History" (8vo., 1686); "Miscellanea Sacra, or Poems on Divine and Moral Subjects" (8vo., 1698); and "Panacea, a Poem on Tea" (1700). He also produced several dramatic works, among which was an alteration of "King Lear" from Shakespeare, which long held the stage to the exclusion of the original. He is however chiefly remembered by his version of the Psalms, made in conjunction with Brady, which, though itself very prosaic, soon superseded that of Sternhold and Hopkins, and is still retained in the "Book of Common Prayer." It was first published under the title of an "Essay of a New Version of the Psalms of David, consisting of the first Twenty, by N. Brady and N. Tate" (8vo., 1695). This was succeeded by "The Book of Psalms, a New Version in Metre, fitted to the Tunes used in the Churches, by N. Tate and N. Brady" (1696), with a "Supplement of Church Hymns" (1700).

TATIAN (TATIANUS), a heretical writer of the 2d century, the time and place of whose birth and death are uncertain, though he calls himself a Syrian. He had travelled widely, had studied various philosophies, and had been a teacher in the pagan schools, before he went to Rome, where he became the friend and associate of Justin Martyr, through whose influence and the study of the Hebrew Scriptures he was converted to Christianity. After the death of Justin (about 165), he seems to have left Rome, returned to the East, adopted views resembling in many respects those of the principal Gnostic teachers, and became the founder of a considerable sect known as Tatianists, but who in the history of the church are confounded if not

identified with the Eucratites or abstemious, the Hydroparastates or water offerers, the Apotactics, the Saccophori, the Aquarii, the Severians, the Continentes, and others. Tatian's doctrine was Gnostic in its theory of æons and of the demiurgus or subordinate creator of the world. He seems to have taught that there was another God named Galdabaoth, the "ruler of the powers," who was father of the devil. He forbade marriage and the use of animal food and wine, substituted water for wine in the service of the eucharist, and required the giving up of worldly goods as the evidence of Christian sanctity. His only important or extensive work that remains is the "Discourse to the Greeks," or to the "Gentiles," as it is incorrectly rendered by the Latin translators, written before he became a heretic. It was regarded with favor, and classed with the works of Irenæus, Justin, and Tertullian, and has passed through many editions, the earliest being that of Zurich in 1546, and the best that of Oxford (8vo., 1700), at the end of Archdeacon Worth's edition of Justin Martyr. It has been repeatedly published in connection with the works of the other apologists, and with the excellent Latin translation of Gesner. Numerous other writings of Tatian are preserved only in the fragmentary notices of the fathers. The account of Tatian and his opinions is best given by Le Nourry in Worth's edition of his works; by the Benedictine Ceillier, in vol. ii. of his "Ecclesiastical Authors;" and by Daniel, *Tatian der Apologet* (Halle, 1837).

TATIUS, ACHILLES. See ACHILLES TATTUS.

TATNALL, a S. E. co. of Georgia, bounded S. by the Altamaha, N. E. by the Cunnahchee, and intersected by the Great Ochopee river; area, about 1,200 sq. m.; pop. in 1860, 4,552, of whom 1,157 were slaves. The surface is level, and the soil sandy and not generally fertile. The productions in 1850 were 71,740 bushels of Indian corn, 46,227 of sweet potatoes, and 321 bales of cotton. There were 2 churches, and 180 pupils attending public schools. Capital, Reidville.

TATTA, a town of British India, in Sindh, situated where the Indus separates into the great E. and W. arms of its delta, 48 m. S. S. W. from Hyderabad; pop. about 10,000. It stands on ground slightly elevated by the ruins of former buildings, the remains of some of which are still visible for a distance of several miles around. During the season that the river overflows its banks the town is almost completely surrounded by water. There are some manufactures of cotton and silk goods, but the trade is not very extensive. It is supposed to be the ancient Pattala. The Portuguese plundered it in 1555, and the British established a factory there in 1758.

TATTLER, the proper name of the wading birds of the snipe family, of the division *tolanca*, as distinguished from the *tringes* or sandpipers; they are often called gambets in England, and *chevaliers* in France. The bill is slender, nearly

straight, about as long as the tarsus, pointed at tip, not grooved for the terminal 4th. gape extending beyond the culmen, terminal half hard and horny, and base covered with a soft skin; wings long; legs and neck elongated; toes connected anteriorly by membrane; tail almost always strongly barred. They are genuine waders, frequenting the water's edge, picking up insects, mollusks, crustaceans, worms, and other aquatic animals from the water, sand, or mud; they are found along rivers and lakes, on marshes, and on the sea shore, sometimes collecting in small companies; they are swift fliers and runners, some of the species taking readily to the water; they perform migrations of considerable extent, going north to breed in spring, and returning through the temperate regions in early autumn, at which time the flesh is fat, juicy, and much esteemed. The French name is derived from the body being mounted on long legs, and appearing as if on horseback. The nest is made on the ground, usually near water, and the young quit it as soon as hatched; in the breeding season they keep in pairs, and the families remain together until spring.—The tall-tale tattler or greater yellow-legs (*Gambetta melanoleuca*, Bonap.) is about 14 inches long, 25 in alar extent, with the bill $2\frac{1}{2}$; wings long, 1st quill the longest; tail short; legs yellow and long; hind toe small. Above it is cinereous of various shades, with lines, spots, and edgings of dull white; lower back brownish black; rump and upper tail coverts white with more or less perfect brownish bands; white below, with brownish stripes on neck and bars of spots on breast; quills brownish black; tail white, with brownish black bands. This bird, sometimes called stone snipe, is found throughout temperate North America and Mexico, preferring large soft marshes and the vicinity of fresh water; it lives with other waders and the smaller ducks; the common name is derived from the habit of uttering its shrill whistle of 4 loud and rapidly repeated notes at the least sign of danger, giving the alarm to all the ducks and other game birds in the neighborhood, to the great disappointment of sportsmen; its notes are easily imitated, calling the bird within gun-shot; the flesh in autumn is excellent eating; the eggs are 4, $2\frac{1}{2}$ by $1\frac{1}{2}$ inches, pale greenish yellow, with brown and purplish gray blotches. The common yellow-legs and the willet will be noticed under these titles.—The wandering tattler (*Heteroscelus brevipes*, Baird) is $10\frac{1}{2}$ inches long, 21 in alar extent, with tarsus $1\frac{1}{2}$, covered with hexagonal scutellae posteriorly, and bill $1\frac{1}{2}$, stout and much compressed; claws short and unusually curved; legs rough in appearance and short; hind toe $\frac{1}{2}$ of tarsus. The color above is uniform dark plumbeous, without white marks; below white, mixed with plumbeous on neck and sides; quills dark brown. This species ranges over the islands of the Pacific and its shores from South America to Australia, and from N. E. Asia to N. W. America and

Washington territory.—The solitary tattler (*Rhyacophilus solitarius*, Bonap.) is $8\frac{1}{2}$ inches long, $18\frac{1}{2}$ in alar extent, with the bill and tarsus each $1\frac{1}{2}$; the bill is a little widened at the end, and curved slightly upward from the middle; lower half of tibiae naked; tail moderate and rounded. It is greenish brown above, with irregularly circular ashy white spots; below white, with greenish brown lines on neck and breast and bands on sides; quills brownish black; 2 middle tail feathers like back, the others white with about 5 transverse bands of brownish black. This is distributed over temperate North America; it sometimes alights on trees, and is expert in catching dragon flies on the wing; the eggs are $1\frac{1}{2}$ by 1 inch, greenish yellow with amber spots and patches.—The spotted tattler or peet-weet (*Tringoides macularius*, Gray) is $7\frac{1}{2}$ to 8 inches long, 13 in alar extent, with the bill 1 inch, and the tarsus rather less; the bill has both mandibles grooved and is tapering; lower 8d of tibiae naked; tail much rounded; outer toe webbed to 1st joint. It is brownish olive green above, with bronzed lustre and lines and spots of brownish black; line over eyes and under parts white, the latter with circular brownish black spots; primaries, secondaries, and outer tail feathers tipped with white, the last with irregular brownish black bars. It is found over temperate North America, in Central America in winter, and also in Europe; it is one of the most common marsh birds of New England, arriving from the south about the beginning of May; it is often called "teeter" from the habit of frequently jerking the tail up and down; it does not associate with other species, nor form large flocks; it alights on branches overhanging the water, and on fences and walls; the flesh is delicious in autumn, and not at all fishy; the eggs are $1\frac{1}{2}$ by 1 inch, grayish yellow with deep brown blotches; both sexes incubate.—The buff-breasted tattler (*Tryngites rufescens*, Cab.), $7\frac{1}{2}$ to 8 inches long, and about 17 in alar extent, is of an ashy brown color above, with black spots on the back, and light yellowish red below; it is a handsome bird, related to the upland plover, like it frequenting dry plains; it is distributed all over North and South America, and in Europe. The last 3 species are often called sandpipers.—Among the European tattlers of the genus *Totanus* (Bechst.), the largest is the greenshank (*T. glottis*, Bechst.), $12\frac{1}{2}$ inches long, ashy brown above and on the sides, with the edges of the feathers spotted with brown; white below, in summer with brown spots; tail with narrow and irregular gray and white bars. It is very noisy in the breeding season, giving the alarm to all the birds within hearing, like the American tall-tale; the food consists chiefly of aquatic insects and small fishes. The American greenshank or Florida tattler (*T. [glottis] Floridanus*, Bonap.) is exceedingly like the European. The dusky tattler (*T. fuscus*, Leis.), 11 inches long, in summer is blackish brown above and slate-colored

below, with the feathers edged with whitish; in winter it is ashy above, white below, and the feet reddish; it feeds chiefly on small fresh water mollusks and insects. The red shank gambet (*T. calidris*, Bechst.), 10 inches long, has the base of the bill red, and the legs yellowish red; in summer it is brown above, with black and a few white spots; white below, with brown spots on neck and breast; numerous brown and white bands on tail; in winter the spots are effaced; it breeds in Holland, where it occurs in large flocks. The wood gambet (*T. glareola*, Bechst.), $7\frac{1}{4}$ inches long, is dark brown above with whitish edgings, white below, and tail with 7 or 8 blackish stripes; the legs are remarkably long; it breeds in the marshes of Europe, tripping across floating leaves with great rapidity and grace.

TATTOOING, the practice of making punctures in the body and introducing into them a pigment which will leave an indelible mark. The word has been introduced into English from the South sea islanders, and seems to be formed by reduplicating the Polynesian word *ta*, to strike. The custom, however, was known among the oriental nations, and was very common among the barbarous races of antiquity. Herodotus says that with the Thracians it marked noble birth, and the want of it low birth. It was practised by the ancient Britons, and even the Anglo-Saxons are rebuked by William of Malmesbury for this custom. It was very generally practised by the inhabitants of the South sea islands and by many of the aborigines of America. With them it was often an exceedingly painful operation, as it took months and sometimes years to complete it fully, and was extended to almost all portions of the body above the knees. In New Zealand, the higher the rank of the individual the more complicated was the pattern marked upon his face and body. Among civilized nations, soldiers and sailors sometimes tattoo themselves.

TAUCHNITZ, KARL CHRISTIAN PHILIPP, a German publisher, born in the early part of the 19th century. He is the son and successor in the business of Karl Christoph Traugott Tauchnitz, who founded at Leipzig in the latter part of the last century a printing house, long celebrated for its cheap, elegant, and accurate editions of classical authors. The son has also published many important works on philology. —**CHRISTIAN BERNHARD**, cousin of the preceding, founded at Leipzig in 1837 a book publishing house, from which have issued since 1842 upward of 500 volumes of a "Collection of British Authors," of a convenient size for ordinary use, and a neat typographical appearance.

TAULER, JOHANN, a German mystic and preacher, born probably at Strasbourg in 1290, died there, June 16, 1861. At the age of 18 he renounced a fortune to enter the Dominican cloister. He studied the scholastic theology in Paris; returned to Strasbourg, where he came under the influence of Master Eckhard, whose vernacular sermons then attracted thronging

audiences; and he was the more impelled to mystical and fervent piety by the violence of the war between the pope John XXII. and the emperor Louis the Bavarian, when the bishop of Strasbourg forbade the clergy to open their churches. He became one of the so called "friends of God," an unorganized brotherhood, including priests, nobles, and burghers in all the large cities, who represented the height of mysticism, denied the special prerogative of the clergy except in the celebration of the sacraments, and with anti-sacerdotal tendencies dwelt upon worship in the heart and life. He preached with wonderful success in Strasbourg, and in the neighboring towns, villages, and convents, journeying to Cologne, where the mystic Ruysbroek was teaching with the greatest influence, and to Basel, where Henry of Nördlingen had resumed his forbidden functions, and where he became known to Nicholas of Basel, the leader of the "friends of God." Notwithstanding the papal interdict, and amid the ravages of the black death (1348-'9), he bestowed the consolations of religion on the forsaken people, preaching in German mingled with Latin, in churches, private assemblies, convents, and the houses of the Beguins. He published in German a treatise on "Following the Lowly Life of Christ;" addressed a remonstrance to the clergy against leaving the dying untended and unabsolved; and denounced ecclesiastical abuses while maintaining the claims of the electors. His mysticism, though it pronounced silence and suffering the most perfect work, was rather active than passive, taught explicitly the love of others, tended not to asceticism but to the amelioration of society, recommended the discharge of all ecclesiastical duties as a preparation for a higher stage of spiritual perfection, and was opposed to the pantheistic tenets of the Beguins. He had been summoned by Charles IV., when at Strasbourg in 1348, to render an account of his faith, but disappeared from the city. He returned there shortly before his death, passed his last hours in the garden of a convent where his only sister had long dwelt as a nun, and was buried in the cloisters. The best of the early editions of his sermons are those of Leipzig (1498), Basel (1531-'3), Halberstadt (1523), and Cologne (1548). There is a modern German translation by Schlosser of his sermons (8 vols., Frankfort, 1836), and of his *Nachfolge des armen Lebens Christi* (Frankfort, 1838). The hymns and treatise on German theology, which have been attributed to him, are of doubtful authenticity.—See Schmidt, *Johannes Tauler von Strasburg* (Hamburg, 1841), and Miss Winkworth, "Life and Times of Tauler," with 25 of his sermons translated from the German (London and New York, 1867).

TAUNTON, a shire town of Bristol co., Mass., situated at the head of navigation on Taunton river, 24 m. from Narragansett bay, 17 m. E. by N. from Providence, R. I., 33 m. S. from Boston, and 26 m. W. from Plymouth; pop. in 1860, 15,880. The town is in shape

an irregular polygon, of which the extreme length from N. to S. is $12\frac{1}{2}$ m., and from E. to W. 11 m. The surface is generally level; half of the land is wooded with forests of pine, oak, beech, and cedar, and there are 5 ponds of considerable size. It is traversed by the Taunton river and two principal branches, the Caneoe and Rumford, the fall in which furnishes power for a large number of mills and factories. Three railroads pass through the town, and the navigation of the river is impeded by ice but a small part of the winter. There are 13 villages within the limits of the town, the largest of which has a population of about 8,000. The number of houses is 1,947. The assessed value of property of all kinds in 1861 was \$7,937,007, of which the real estate was valued at \$5,157,228, and the personal estate at \$2,779,784. The amount of grain annually brought into the town is about 500,000 bushels; and 21 sloops and schooners, of 50 to 250 tons (in the aggregate 2,770 tons), ply regularly between Taunton and the principal cities on the coast. There are in the town 5 cotton factories, a flannel factory, 2 locomotive factories, 3 machine shops, 3 tack factories, 8 foundries, an iron rolling mill, nail and shovel factory, 2 britannia and silver plating factories, a screw factory, a gas factory, a paper mill, 8 factories of oiled and enamelled cloth, a sewing machine factory, 2 box and cask factories, a crucible factory, 8 factories of fire brick and stove linings and one of stone ware, a marble and monument factory, and a company for manufacturing copper, belonging to which are two large rolling mills, a kettle mill, and a roller mill; the whole employing 8,600 persons, with an aggregate capital of \$2,500,000, and an annual product of \$5,500,000. The Taunton copper company, the oldest and largest in the United States, has been incorporated more than 80 years. Its products are copper, sheet zinc, and yellow metal sheathing, to the amount annually of 2,500 tons, of the value of \$1,250,000. Beside these larger establishments, there are numerous smaller tool shops, 7 saw mills, 5 grist mills, and 12 brick yards. Taunton has from the beginning been noted for its manufacture of brick and iron, large quantities of which are annually exported. Taunton and Taunton river are also proverbial for their herring fisheries, the privileges of which are still annually sold, though few of the inhabitants at present pursue this branch of industry. Large quantities of shad and alewives are taken from the river in April and May.—There are in Taunton 16 church buildings (4 of them of stone, and 3 of Gothic architecture), and 19 religious societies, viz.: 2 Baptist, 1 Christian, 5 Congregationalist (one of them Unitarian), 1 Episcopal, 2 Freewill Baptist, 3 Methodist, 2 Roman Catholic, 1 Spiritualist, 1 Swedenborgian, and 1 Universalist. The number of school houses is 23, in which 66 teachers are employed, and 3,000 children are instructed. The state hospital for the insane occupies a conspicuous site,

with grounds of more than 140 acres, and accommodates over 400 patients. There are also in the town an academy, incorporated in 1792; 2 social libraries, with nearly 6,000 volumes; a spacious court house, with fire-proof building attached; a jail; 5 halls for public purposes; 4 hotels, one of them remarkable for its architectural elegance; 3 printing offices, publishing 1 daily and 2 weekly newspapers; 3 banks of circulation, with an aggregate capital of \$1,050,000; an institution for savings; and 2 insurance offices. The streets of the central village are well laid out, lighted by gas, and adorned by shade trees of various kinds. There are many elegant private residences, some of great cost, to which are attached gardens and conservatories. Among the objects of curious interest are a grove of oaks more than 800 years old, and the singular phenomenon of an elm tree 70 feet in height growing in the centre of an aged apple tree, the trunk of which completely clasps it, both trees being in a flourishing condition.—Taunton was settled in 1638 by a company from Taunton in England, from whom a large proportion of the present natives of the town are descended. Its first minister was William Hooke, who afterward was noted in the English civil war, and was chaplain to Oliver Cromwell. In the Indian war of the sachem Philip, the town was protected from harm by the friendship of that chief for Thomas Leonard. Philip's favorite hunting ground was within the limits of the town.

TAUNTON, a town of Somersetshire, England, situated on the Tona, 46 m. S. W. from Bath and 141 m. W. S. W. from London; pop. in 1861, 14,660. It stands in a fertile valley, and is surrounded by gardens, orchards, and rich meadows. It has manufactures of silk, lace, crapes, mixed and woollen goods; and the ale of its breweries is celebrated. The trade is principally in agricultural produce, live stock, and coal, and weekly and monthly markets are held. The Taunton and Bridgewater canal and the Bristol and Exeter railway afford means of communication with other parts of the country.—Taunton is a place of great antiquity, and is supposed to have been a Roman station. In 1685 the duke of Monmouth was proclaimed king at Taunton, and the inhabitants afterward suffered from the cruelties of Jeffreys, who held his "bloody assizes" there. The town has returned 2 members to parliament since 1265.

TAUNUS MOUNTAINS. See WESTERWALD.

TAURIDA, a S. government of European Russia, lying on the Black sea and the sea of Azof; area, 24,140 sq. m.; pop. in 1858, 687,843. The government is composed of the Crimea or Tauric peninsula (anc. *Chersonesus Taurica* or *Soythica*; see CRIMEA) and the Nogai steppe. The latter, including all the territory lying N. of the Crimea to the river Dnieper and the boundary line of the government of Ekaterinoslav, is a dry elevated country, with a sandy soil impregnated with salt,

and without trees, but with some rich valleys that produce luxuriant herbage. There are a few small streams which flow into the sea of Azof, but the only rivers of importance are the Dnieper on the N. W. frontier, the Konakaia on the N., and the Berda on the E. There are several lakes of considerable size, one of which covers an area of 108 sq. m., and is only separated from the sea of Azof by a sandy spit. Numerous tongues of land formed by alluvial deposits project from the S. coast, the most extensive of which lies S. of the estuary of the Dnieper, and was anciently called Achilleos Dromos, or Racecourse of Achilles. The climate is much the same as that of the Orimea. Salt, saltpetre, and naphtha are abundant. The greater part of the inhabitants are Tartars. The capital of Taurida is Simferopol, and the principal seaport and naval station is Sebastopol.

TAUROMENIUM, an ancient Greek city on the E. coast of Sicily, about half way between Messina and Catana, founded on the hill of Taurus, overlooking the sea, after the destruction of Naxos, 8 m. to the N., by Dionysius the Elder of Syracuse in 408 B. C. In 394 Dionysius unsuccessfully besieged it for a long time, but it fell into his hands in 392. In 358 Andromachus, the father of the historian Timæus, is said to have collected together all the exiled Naxians, and established them at Tauromenium. In 845 Timoleon landed here, but left Andromachus in possession of power, which he exercised mildly. Subsequently it fell into the hands of Hiero, king of Syracuse. Under the Romans it enjoyed great privileges; but during the servile war in Sicily (134-132) it was occupied and desperately defended by the insurgent slaves. By Augustus it was made a colony, and from its strong position was one of the last places taken from the Greek emperors; but in A. D. 906 it was captured by the Saracens, who destroyed it totally. The modern Taormina, a village of about 8,500 inhabitants, occupies the site of the ancient city, vestiges of which still remain.

TAURUS, a range of mountains in Asia Minor, forming the watershed between the waters flowing into the Mediterranean and those into the Black sea. It consists of two principal chains, Taurus, the higher and longer, on the S., and Anti-Taurus on the N., and with its ramifications forms on 3 sides of the peninsula, and particularly on the N. and S., a series of terraces, rising in the portion lying between Taurus and Anti-Taurus into a broad plateau abounding in salt lakes, and identical in character with the steppes of central Asia. The commencement of the chain on the W. is a disputed point, some alleging that it begins with Samsum-Dagh (anc. *Mycale*) opposite the island of Samos, while others regard it as beginning at Cape Khelidonia, near the gulf of Adalia. It follows and repeats the sinuosities of the coast, and in crossing the ancient province of Pamphylia takes the name of Takhtali-Dagh, attaining an elevation of nearly 7,000 feet; in

the ancient Pisidia and Isauria it is called Gok-Dagh; in the ancient Lycaonia and Cilicia, where it rises to the height of 10,000 feet, it is called Ara-Dagh, Bulghur-Dagh, and Ala-Dagh; toward the source of the Jyhoon (anc. *Pyramus*), it throws off a spur toward the S. under the name of Giaur-Dagh, which, meeting further E. the Akma-Dagh, forms the celebrated defile anciently known as the Amanian gates; the main chain, trending N. E. under the name of Akar-Dagh, crosses the Euphrates, separates its E. branch from the sources of the Tigris, and joins near Bayazid the Armenian system of mountains. Anti-Taurus, separating from the Taurine plateau at the N. of Cilicia, rises in the lofty peak of Mt. Arjish (anc. *Argæus*) to the height of 13,000 feet; it then divides into two branches, one extending eastward across the Euphrates to the Caucasian mountains; the other turns westward, and, under the name of Hassan-Dagh, Sultan-Dagh, or Nurad-Dagh, terminates near Broussa, in the ancient Olympus, about 5,200 feet in height. Numerous geographers, however, apply the name Anti-Taurus to the eastern branch alone. A branch of this chain follows the S. coast of the Black sea as far as Trebizond, and forms the N. boundary of the great triangular plateau of upper Asia Minor. Strabo, Eratosthenes, Dicaearchus, and other ancient geographers applied the name Taurus to a continuation of this range eastward across the Asiatic continent, which they erroneously believed to follow the same parallel to the E. shores of China.

TAUTOG. See **BLACKFISH.**

TAVERNIER, JEAN BAPTISTE, a French traveller and merchant, born in Paris in 1605, died in Moscow in July, 1689. His father was a map engraver from Antwerp, and the son learned the jeweller's trade, and before his 22d year had traversed France, England, the Low Countries, Germany, Switzerland, Poland, Hungary, and Italy, serving at different times as page or general attendant in noble families and as a soldier. In 1680 he accompanied two young French noblemen to Palestine, and thence extended his travels to Ispahan, and returned in 1683 to France, where he was appointed comptroller of the household of the duke of Orleans. In 1688 he started again for the East, and between 1680 and 1679 made 6 journeys into Asia, traversing Turkey in Europe and Asia, Persia, Independent Tartary, Cabool, India, Further India, Malacca, Sumatra, and most of the Dutch East India possessions, and penetrating to the confines of China. On his return from his 6th journey, enriched by his traffic in diamonds and other rare oriental products, he was ennobled by Louis XIV., purchased the estate of Aubonne upon the shores of Lake Geneva, assumed the title of Baron d'Aubonne, and lived in princely style, employing a writer named Chappuzeau to prepare a narrative of his travels. The frauds of his nephew, who had the management of his affairs, obliging him to sell his estate, he remov-

ed to Berlin, and was nominated by the elector of Brandenburg director of a new East India company. In 1688 he set out for the East Indies by way of Russia, but was seized with fatal illness at Moscow. The accounts of his travels are contained in *Nouvelle relation de l'intérieur du sérail* (4to., 1675), and *Les six voyages de Jean Baptiste Tavernier, écuyer, baron d'Aubonne, en Turquie, en Perse et aux Indes* (8 vols. 4to., 1676-'9). They were translated into English (fol., London, 1677).

TAXES (Lat. *taxo*, to rate or value; Gr. *taxeo*, to arrange), the contributions paid by the inhabitants of a country for the use of the government. In a free government taxes are laid by the representatives of the people, and of course with the consent of those who are to pay them; in despotic governments they are levied at the will of the ruling power. Taxes are usually divided into direct and indirect; the former include all assessments made upon the real or personal estate of the taxpayer, upon his income, or upon his head; the latter comprise duties upon imports and exports, excises, licenses, stamp duties, and the like. Taxation in some form is of very ancient origin. Among the Hebrews, in the time of the theocracy, there was a capitation tax of a half shekel (about 80 cts.) payable by every male in the nation; a tribute of the first fruits, and of the first born of their domestic animals, which might however be commuted for money at a fixed rate; a redemption tax for the first born male of the family; and a first and second tithe for the support of the Levites and of the service of the tabernacle, and every third year a third tithe for the benefit of the poor, and so in some sense a poor rate. After they adopted the regal form of government, the taxes were greatly increased. In addition to the exaction of a tithe of all the property, not of the income alone, the kings exacted a tithe of personal service of both sexes, or its equivalent in money, and occasionally, in addition to this, a heavy capitation tax (2 Kings xv. 20), or a special assessment. There were also, at least in the later periods of Jewish history, taxes levied upon houses, and transit taxes and tariffs on the introduction of foreign merchandise. Presents also formed with the Jewish, as with most oriental monarchs, a species of voluntary contribution of considerable amount. Solomon was successful in collecting a large revenue; and the stoning to death of Adoram, "who was over the tribute," and the secession of the 10 tribes at the commencement of the reign of his son and successor, indicate how oppressive had been the taxation which caused such an alienation of feeling from the popular dynasty of David.—In the Athenian republic there were no direct taxes, either on personal or real estate; the sources of revenue were the lands of the republic, fines and confiscations, the royalty of $\frac{1}{4}$ of the products of the mines, a capitation tax on freedmen and foreigners resident in the republic, customs duties on foreign commodities

and merchandise, on which a tariff of 2 per cent. was levied, some excise duties, licenses of markets and houses of prostitution, and tribute paid by other cities and islands subjected to their sway. The imposts, licenses, &c., were generally farmed to companies, which gave security for their prompt payment. In times of war, extraordinary contributions were levied on wealthy citizens, or an appeal was made to their patriotism. The common people, so far from paying any tax, except the duty on the goods they purchased, received from the state large appropriations for public games and spectacles. In Rome, under the republic, the spoils of conquered nations and the annual tribute exacted from them defrayed the greater part of the expenses of the state; but under the empire it was found necessary to resort to numerous devices of taxation to replenish the often exhausted treasury of the emperors; portions of the territorial revenues were sequestered, capitation taxes levied, tolls, taxes on corn, and legacy and hereditary duties collected, heavy sums exacted for the privilege of Roman citizenship, &c. During the middle ages, under the feudal system, there was no system of taxation. The kings were maintained by the products of their land, and in case of war their vassals, the barons and knights, were under obligation to furnish their quota of men-at-arms equipped and provisioned without expense to the monarch; and this military service was performed by their tenants by way of rental for the lands they cultivated. The first approach to modern systems of taxation was made during the middle ages by the republic of Venice, which, being largely engaged in commerce and holding colonial possessions in Greece and elsewhere, was obliged to maintain a large army and navy, to defend its fleets and colonies from the Turks, and to maintain its aristocracy. To meet these expenses, a direct and an indirect tax were levied, the former on the lands of the republic, the latter in the form of duties on the goods manufactured and the merchandise imported; these duties, which brought in a large revenue, were imposed on the necessaries as well as the luxuries of life; salt, flour, oil, spices, food of all sorts, wine, soap, silks, jewelry, were all taxed heavily. In France, prior to the revolution, though Sully and Colbert were both eminent as financiers, and did much to put the finances of the kingdom in a prosperous condition, there was a serious obstacle to any equitable system of taxation in the fact that the nobility and clergy, the privileged classes as they were termed, were exempted from its burdens, which rested necessarily with crushing weight on the *bourgeois* and *ouvriers*; and to add to their distress, most of the taxes were farmed, often to men who exacted much more than the legal amount. In England the finances for centuries were badly managed; there was little encouragement to industry, and the taxes, whether direct or indirect, were insufficient for the ex-

penses of the government. The privileged classes were exempted as in France. Resort was often had to the sale of monopolies, and to forced loans, contributions, and confiscations, to procure the means of gratifying the monarch's extravagance, or the revenue necessary for conducting wars. In most of the other countries of Europe there were no taxes levied on the clergy or the nobles. In the countries of western Asia, the government with the right of taxation of provinces was bestowed on favorites, or sold to the man who would pay highest for it; and as the duration of the government of these rulers was short, they practised the most cruel extortion upon their unfortunate subjects, completely annihilating industry, and often transforming countries once prosperous and populous into desert wastes, by their oppressions.—It is only within the last 100 years that the best methods of taxation have come to be understood, and the possibility of collecting such sums as are necessary for the maintenance even of a costly government, without impairing the prosperity of the people who are taxed, comprehended. Sir Robert Walpole was one of the earliest statesmen to perceive the advantages of the excise tax over direct taxation on land or polls; but the violent opposition which his "excise scheme" elicited compelled its postponement. Adam Smith laid down the maxims of taxation, as follows: "1. The subjects of every state ought to contribute toward the support of the government, as nearly as possible, in proportion to their respective abilities; that is, in proportion to the revenue which they respectively enjoy under the protection of the state. 2. The tax which each individual is bound to pay ought to be certain, and not arbitrary; the time of payment, the manner of payment, and the quantity to be paid, ought all to be clear and plain to the contributor and to every other person. 3. Every tax ought to be levied at the time, and in the manner, in which it is most likely to be convenient for the contributor to pay it. 4. Every tax ought to be so contrived as both to take out and keep out of the pockets of the people as little as possible over and above what it brings into the public treasury of the state." The taxes of most of the nations of Europe prior to the present century were so levied as to violate nearly all of these maxims. In 1598, according to Sully, out of 150,000,000 livres drawn from the people of France by taxation, only 80,000,000 found its way into the public treasury. As late as the administration of M. Necker, the cost of collecting the taxes was 10½ per cent. In 1857 the tax of the United Kingdom, amounting to about £80,000,000, was collected at a cost of 4 per cent., and of this the collection in Ireland was the larger part. The farming of taxes, once very generally practised, is now for the most part relinquished, but in Turkey a part of them are still farmed. The necessities of Great Britain and France, growing out of their protracted wars and large debts, have compelled a

resort to heavy taxation, and the exercise of great financial skill in so distributing the taxes as to make their burden tolerable. In Great Britain a heavy tariff is laid upon those foreign goods which compete with British manufactures, and a moderate but productive one on imported articles of general necessity like tea and coffee, foreign paper, &c., while wine and tobacco are heavily assessed. Excise duties are laid on distilled and malt liquors of British manufacture, as well as on domestic produce. Licenses are required for the sale of spirituous liquors, and the keeping of inns, post horses, hackney carriages, stage coaches, railways, &c. Newspapers were subjected to a compulsory stamp duty till 1855; it is now optional, and if paid exempts the paper from postage. All official and legal documents must be executed on stamped paper; duties are also collected on bills of exchange and bankers' notes; the probate of wills and taking out of letters of administration are charged with duties proportional to the amount of personal property, from 2½ to 3 per cent. being charged the heirs when there is a will, and from 3½ to 4½ per cent. where letters of administration are issued. Lands, houses, servants, horses, carriages, dogs, watches, and jewels are taxed; and there are beside taxes on income, and revenues from the post office, crown lands, timber, &c. The customs and excise duties ordinarily constitute about ¼ of the entire revenue, and the income tax nearly ½ and stamps ½ of the national tax, which usually amounts to about £72,000,000; and the local taxes, tithes, poor rates, &c., amount to £20,000,000 more. The total budget of France for the present year (1862) is 1,974,070,028 francs, of which nearly ½ is the product of direct taxes, ½ customs and salt duties, ¼ excise and other indirect taxes, while the capitation tax, stamp duties, crown lands, and assessments on forests and fisheries, amount to about ¼ of the whole. Of the revenues of Great Britain £28,000,000 is paid annually as interest on the national debt, and of those of France in 1862, 602,215,602 francs.—In the United States, the national government has levied a direct tax only in 8 instances, and never for a sum exceeding \$6,000,000, until 1861; the customs and occasionally excise revenues and the receipts for the public lands having been sufficient to defray the expenses of the government, and to liquidate a portion of the debt. The enormous expenditures of the existing civil war (1861-2), and the reduced receipts from customs, have compelled the levying of a direct tax intended to be sufficient to pay the interest of the debt, and to furnish a sinking fund to extinguish the principal. At the extra session of congress on Aug. 6, 1861, a bill was passed levying a direct tax of \$20,000,000, partly on lands and partly on incomes; the duties on imports from foreign countries were also increased. The direct tax, which was to be assessed in the spring of 1862, has been generally assumed by the states themselves. During the

present session (1861-'2) of congress, the necessity of raising a large revenue has led to the consideration of various plans of taxation. An elaborate bill, providing for excise duties on all kinds of manufactures, tolls on all passenger travel, duties on plate, watches, &c., licenses from all classes of dealers, a tax on incomes over \$600, legacy and succession duties, and stamps on all kinds of legal and commercial papers, patent medicines, telegrams, &c., passed the house of representatives by a large majority, and is now (May, 1862) under consideration in the senate, where it has been materially modified. Other plans, embracing entirely different principles, are also maturing, and may be substituted for that now pending. The several states, being debarred by the constitution from collecting duties on imports, have raised the revenues necessary for their state expenditures by direct taxes on lands, houses, and personal property; specific taxes on banking and insurance capital, railroads, and turnpikes; bonuses from banks, &c.; licenses on auctions, peddlers, public houses, the retailing of spirituous liquors, gunpowder, &c.; and in most of the states by capitation taxes. A part of the state taxes are still payable in labor in some of the states, though the amount thus paid is now mostly confined to highway taxes, and to the frontier states, where money is less abundant than labor. No state has hitherto levied a general income tax, though in some cases particular professions have been assessed, nor any except Virginia and Pennsylvania an inheritance tax. Maryland and New Jersey collect a transit tax from the railroad companies for all passengers over certain roads. The following table gives the direct and indirect tax of each state government in the United States for state purposes, together with the state valuations, in most cases for 1860:

TAXES AND VALUATIONS OF THE STATES, 1860.

States.	Federal population.	Valuation.	Tax.
Maine.....	623,276	\$190,211,600	\$336,899

Beside the state taxes, there are also in all the states county, town, and road taxes, and in most of them school and municipal taxes, the whole amount of which it is impossible to ascertain. In the states which include large cities they are often of great amount. In New York the local taxes in 1860 were \$12,840,814, of which \$9,863,002 was in the county of New York. In Ohio in 1859 the local taxation was \$6,618,848. It would not probably be far from the truth to estimate it at 8 times the amount of the state taxes. It is almost an invariable provision of the state constitutions that no taxes can be levied on any pretence without the consent of the people or their representatives; that they shall be levied and collected only for public purposes; and that all revenue bills shall originate in the lower house of the legislature. Further safeguards are raised against the power of taxation by provisions that no money shall be drawn from the treasury except in compliance with appropriations made by law, and that there shall be an annual report of income and expenditure. In all the states the property of the federal government is by law specially exempted from taxation, as are also usually churches, benevolent institutions, colleges, academies, school houses, and the funds of charitable and scientific societies, and places and rights of burial. The only exemption of classes from taxation are clergymen to a certain limit in some of the states, paupers in all, and Indians and negroes in those northern states in which they have no vote. In the New England states, aliens who are likely to become chargeable to the town, or whose families are in danger of becoming paupers, are not suffered to acquire a residence, and thereby a right to public relief, their taxes being remitted by the town authorities to prevent it. The assessors in the several jurisdictions of the states are generally required to prepare assessment rolls, in which shall be set forth the names of all taxable inhabitants, the quantity and value of land or the house or houses taxed to each person, and the value of all personal property. Usually farming lands and dwellings are set in the assessment rolls at less than their value, as yielding a smaller percentage of income than most descriptions of personal property. These assessment rolls, when delivered to the collector, constitute his authority for the collection of the taxes.—The following are a few of the points relative to taxation which have been settled by our highest courts. The tax must be levied in all cases by the tribunal or body of persons to whom the power is delegated.

The levy of a tax by a town meeting, not called according to the prescribed form, is illegal and void. When a statute requires a list to be delivered to the collector on or before a given day, a delivery either before or after that day confers no authority on him to collect the tax. As a tax for an illegal purpose is void, the object of each assessment ought to be so designated that a citizen may resist payment of any one which is illegal; thus state, county, and town taxes should be separately designated, since one may be lawfully levied and another not so. In all respects the requirement and direction of statutes concerning taxes must be carefully observed. The policy of the law is to throw around the property of the citizen the most complete possible protection, and the tax must not only be right and just in itself, but it must be levied in all respects in conformity to law, or the taxpayer is justified in resisting its collection. The measures to compel the collection of taxes properly levied are generally similar in the several states. The tax if paid at an early date is reduced by a small percentage for prompt payment; if not paid by a certain time, it is increased by the interest; after a further period, interest is reckoned at 12 per cent. or more; after another delay, if real estate, it is sold for the taxes, though an opportunity of redemption is given for 2 or 8 years; if personal estate, a distress of personal property is made, and fines and costs added; and in some states imprisonment is added to the penalties.

TAXIDERMY (Gr. *ταξις*, arrangement, and *δερμα*, skin), a term originally used to designate the methods of preserving skins, so as to retain their natural appearance; but it is now applied to the art of preserving the whole animal body for collections of natural history. The art has been recently brought to a high state of perfection. By the methods now in use small animals are immersed in alcohol, the strength of which should be adapted to the particular object to be preserved, as very strong alcohol may destroy the colors, and injuriously harden the integuments. Tartar emetic or corrosive sublimate added to it increases its preserving quality and prevents its use for other purposes. A special preparation known as Goadby's aluminous solution is sometimes employed, composed of rock salt 4 oz., alum 2 oz., corrosive sublimate 4 gr., boiling water 2 quarts; and another known as his saline solution is composed of rock salt 8 oz., corrosive sublimate 2 gr., boiling water 1 quart. A solution of corrosive sublimate may be employed, or of common salt, and even oil may be resorted to, when more suitable materials are wanting. The object to be preserved should be suspended in the liquid, without contact with the sides or bottom of the vessel; and after remaining for some time the liquid should be changed, but that used first may be kept to be again employed in the same way. It is recommended to employ, instead of glass jars, square

copper cans or wooden kegs made with a large mouth, with a cap or bung fitting air-tight, and to put the smaller specimens in porous bags before introducing them into the liquid. It is well also to wrap each one of them in cotton; and the vessel must in all cases be completely filled to prevent injury by motion. Specimens of considerable size should have incisions in the abdomen, that the alcohol may more readily reach the internal parts, and injections of alcohol may also be made. This method of preservation is applicable to all the small quadrupeds, reptiles, crustacea, fishes, most of the insects (excepting the lepidoptera), the skins of the larger animals, &c. Insects are often preserved by fastening them down with pins thrust through their bodies into a lining of cork or soft wood forming the bottom of paper boxes. They may, as collected, be put into small vials with wide mouths, containing a little camphor, or, still better, a sponge soaked in ether, which soon kills them. The larger animals are skinned, and the skins are put into alcohol, or coated on the inside with arsenic and then dried; but if arsenic cannot be had, salt may be used, and immersion in a strong brine of alum and salt is very efficacious. Insects are kept from the skins by sprinkling in the hair powdered green or blue vitriol. The skins are taken off with especial care to retain the form, leaving the bones of the toes, and also the skulls of the smaller animals. The skeletons may be separately prepared and preserved, to be afterward set up in their natural position with wires. All parts liable to decompose are carefully removed, and arsenic or arsenical soap is applied wherever decomposition may be feared. The arsenic may be applied either in a state of dry powder to the moist skin, or mixed with alcohol and water to the consistency of molasses and put on with a brush. The preparation of the skins of birds is a matter of much delicacy. When the bird is killed with shot, the holes should be immediately stopped with cotton, as also the mouth and nostrils; and if the bird is small it should be thrust head foremost into a cone of paper prepared for the purpose, the open end of which should be folded down. If any of the feathers have been crumpled or bent, they may be partially restored by dipping them into hot water. Before removing the skin, the principal dimensions of the bird are to be carefully noted, so that they may be retained. The skinning, which proceeds from an incision extending back from the lower end of the breast bone, is made with especial care to avoid soiling the feathers. As the skin is loosened cotton is inserted to prevent its adhering to the body; and the legs are in succession stripped of their covering through the single incision made, and are cut off with the scissors or a knife at one of the lower joints, leaving the feet attached to the skin. The tail is in like manner separated by cutting through the last joint of the vertebrae. The body is then suspended by a hook introduced

into the lower part of the back or rump, and the skin is inverted and carefully loosened. Before reaching the wings, they are somewhat softened by stretching and pulling, and when the skin is loosened around the first bone, this is cut through the middle, or, if sufficiently exposed, at the elbow joint. When the skull is exposed, much care is required to remove the delicate membrane of the ear without tearing it; and similar care is required not to cut through the membrane that covers the eye. The eyes themselves are removed from their sockets and the brain from the skull, several cuts being made through the latter near the base of the lower jaw and through the roof of the mouth, &c. Every particle of muscle and fat being removed from the head and neck, the preservative is abundantly applied in and about the skull and also to the inside of the skin, and the parts are then restored to their natural position. The muscle and fat are also removed from about the wings, legs, and tail, and if necessary an incision is made along the forearm so as to expose the two joints for this purpose. The remaining bones of the two wings should then be tied together inside of the skin by strings drawn up till the wings are brought to the same distance apart as when attached to the body. Skins may be transported in this condition, or be immediately stuffed. This operation is performed by introducing cotton through the mouth into the orbits and upper part of the throat until these acquire their natural shape. A roll of cotton is then put into the skin and pushed firmly up the neck to the base of the skull. The body is then filled, not quite to its original dimensions, and the incision in the skin is sewed up. The bird may be kept in a cylinder of paper into which it is thrust, the legs and mandibles being first tied together and the feathers carefully adjusted. If the specimens are to be set up in natural positions, wires are introduced in the course of the stuffing and secured in the wings, neck, and feet, coming out through the latter. Glass eyes are manufactured and sold to be introduced in the orbits in imitation of the natural ones. In skinning birds with large heads and long necks, it is sometimes necessary after reaching the base of the skull to cut off the neck, and then drawing back the head make an incision on the outside down the back of the skull in order to skin the head. The process of skinning is variously modified according to the different characters of the animals. To protect hair or fur against moths and other destructive insects, the skins should be soaked in a solution of corrosive sublimate in alcohol or whiskey for a day to several weeks according to the size; they must then be thoroughly washed or rinsed in clean water. Finely powdered green vitriol sprinkled in feathers is an excellent protection against moths.—The larger fishes are also skinned and stuffed; but in many cases it is sufficient to preserve only one half the fish, and the method then pursued is as fol-

lows. The fish is laid on a table with the left side up, the fins are spread out, and a piece of paper is laid under each one that is to be preserved. When the fins are dried, the fish is turned over and a cut is made through the skin from the upper and posterior part of the head along the back to the tail, across the base of the caudal fin down, and thence along the belly to the lower part of the head again, cutting below the articulations of the dorsal, caudal, and anal fins. The body is then separated from the left side of the skin, commencing at the tail, and is cut off near the head. The inside of the head is then cleaned out and the eye is removed, leaving only the cornea and pupil, which are covered with a piece of black paper of the size of the orbit. The preservative is then applied, and the head and section of the body are filled with cotton, when the skin is turned over, pinned down upon a board at the base of the fins, and left to dry.—Detailed directions for preserving objects of natural history are given by Prof. S. F. Baird, in the "Report of the Smithsonian Institution" for 1856. See also Swainson's "Taxidermy," forming a volume of Lardner's "Cabinet Cyclopædia."

TAY, a river and loch of Perthshire, Scotland. The river rises in a small loch on the border of Argyleshire, and is called the Fillan until it passes through Loch Dochart, 8 or 9 m., and thence to Loch Tay, 10 m. further, it is generally known as the Dochart. Near Loch Tay it receives the Lochie, and below that loch the river Lyon and numerous other tributaries. Its whole length is nearly 120 m., and its course describes almost a semicircle from N. E. to S., until it reaches Perth, whence it flows nearly E. through the frith of Tay into the North sea. It has tide water to Perth, and is navigable that distance for vessels drawing 9 feet. From this point it flows through the finest valley of Scotland, and discharges a larger volume of water than any other river of the British islands. Its salmon fisheries are celebrated. Loch Tay is a romantic lake about 14 m. long and 1 m. wide, with steep, precipitous banks, and is said to have been sounded to a depth of 600 feet. The mountain Ben Lawers, on its N. W. shore, rises to a height of 3,945 feet.

TAYGETUS. See LACONIA.

TAYLOR, the name of counties in 6 of the United States. I. A N. W. co. of Va., intersected by the Tygart's Valley river; area, 130 sq. m.; pop. in 1860, 7,468, of whom 112 were slaves. The surface is very hilly, and the soil in some parts fertile. The productions in 1850 were 101,118 bushels of Indian corn, 28,995 of wheat, 41,499 of oats, 4,051 tons of hay, and 87,110 lbs. of butter. There were 11 churches, and 703 pupils attending the public schools. Iron ore and bituminous coal are abundant. The value of real estate in 1856 was \$1,226,984, being an increase of 10 per cent. since 1850. Capital, Williamsport. II. A W. co. of Ga., formed since the census of 1850, bounded E. by

Flint river and drained by White Water and other creeks; area, about 400 sq. m.; pop. in 1860, 6,000, of whom 2,397 were slaves. The surface is undulating and the soil generally fertile. It is intersected by the Muscogee railroad. Capital, Butler. III. A new co. of Fla., bounded S. W. by Appalachee bay and W. by the Aucilla river, and drained by the Fenaholloway; area, over 1,000 sq. m.; pop. in 1860, 1,384, of whom 125 were slaves. IV. A W. co. of Texas, drained by affluents of the Brazos and Colorado rivers; area, 625 sq. m. It was still unorganized when the census of 1860 was taken. Capital, Taylor. V. A central co. of Ky., drained by Green river and its affluents; area, about 275 sq. m.; pop. in 1860, 7,481, of whom 1,597 were slaves. The surface is hilly and the soil fertile. The productions in 1850 were 365,085 bushels of Indian corn, 91,639 of oats, 10,087 of wheat, and 592,106 lbs. of tobacco. There were 17 churches, and 461 pupils attending public schools. The proposed route of the Danville and Nashville railroad passes through this county. Capital, Campbellsville. VI. A S. W. co. of Iowa, bordering on Mo., and drained by East Nodaway, One Hundred and Two, and Platte rivers; area, 560 sq. m.; pop. in 1860, 3,589. The surface is generally level and the soil fertile. The productions in 1859 were 137,162 bushels of Indian corn, 5,604 of wheat, 4,163 lbs. of wool, 54,009 of butter, and 2,007 gallons of sorghum molasses. It is on the line of the projected southern railroad. Capital, Bedford.

TAYLOR, BAYARD, an American author and traveller, born in Kennett Square, Chester co., Penn., Jan. 11, 1825. At 17 years of age he became an apprentice in a printing office in West Chester, and at the same time a contributor of verses to the periodical press. In 1844 he published a volume of poems under the title of "Ximena," and having collected a small sum of money, the fruits of his past and prospective literary labors, he departed on a European tour, principally pedestrian, of which he published an account on his return to America in 1846, entitled "Views a-Foot, or Europe seen with Knapsack and Staff." After editing for a year a newspaper in Phoenixville, Penn., he removed to New York, and wrote for the "Literary World," and subsequently for the "New York Tribune," of which journal he became in 1849 a part proprietor and associate editor. Soon afterward he commenced the first of a series of extensive foreign tours, which have since occupied the greater portion of his time, and the narratives of which have regularly appeared in the columns of the "Tribune" in the form of epistolary correspondence, and subsequently been gathered into volumes of travels. Visiting California in 1849, then the focus of attraction to adventurous spirits on account of the recent discovery of its gold fields, he returned home by way of Mexico, and published in 1850 "El Dorado, or Adventures in the Path of Empire." In the summer of 1851 he set out on a pro-

tracted tour in the East, in the course of which he ascended the Nile to lat. 12° 30' N., and afterward traversed large portions of Asia Minor, Syria, and Europe; and in the latter part of 1852 he made a new departure from England, crossing Asia to Calcutta, and thence proceeding to China, where he was enabled to join the expedition of Commodore Perry to Japan. Returning to New York in Dec. 1853, he published in the succeeding year his "Journey to Central Africa" and "Lands of the Saracen," followed by "Visit to India, China, Loo-Choo, and Japan in 1853." His subsequent travels are indicated by the titles of the volumes recording them: "Northern Travel; Summer and Winter Pictures of Sweden, Denmark, and Lapland" (London and New York, 1857), and "Travels in Greece and Russia, with an Excursion to Crete." Mr. Taylor's first considerable volume of poems was entitled "Rhymes of Travel, Ballads, and other Poems" (1848), and was followed by a "Book of Romances, Lyrics, and Songs" (1851); "Poems of the Orient" (1854); and "Poems of Home and Travel" (1855), the last named volume, according to the author's statement in the preface, comprising such pieces only as he desired to acknowledge. In connection with his travels he has also produced "At Home and Abroad; a Sketch Book of Life, Scenery, and Men" (1859; 2d series, 1862); and he has edited a "Cyclopædia of Modern Travel" (8vo., Cincinnati, 1856). A volume of poems, entitled "The Poet's Journal," and a novel of American life, are announced to appear in the course of 1862. Mr. Taylor's poem of "The American Legend" was originally delivered before the Phi Beta Kappa society of Harvard university in 1850.

TAYLOR, BROOK, an English mathematician, born at Edmonton, Aug. 28, 1685, died at his estate of Bifrons in Kent, Dec. 29, 1731. In 1701 he entered St. John's college, Cambridge, where he soon distinguished himself as a mathematician, in 1708 wrote his treatise on the "Centre of Oscillation," which was not published till some years later, in 1709 took the degree of LL.B., and in 1712 was chosen a fellow of the royal society. He had already solved Kepler's problem, and was corresponding with Dr. Keill on the most abstruse mathematical topics. From 1714 to 1718 he was secretary of the royal society, to which he contributed papers of great ability on magnetism and mathematical subjects. His *Methodus Incrementorum* (1715) is the first treatise in which the calculus of finite differences is proposed for consideration. In 1715 he conducted a controversial correspondence with Count Raymond de Montmort on the tenets of Malebranche, and in 1719 he published his "New Principles of Linear Perspective." Among his manuscripts are a "Treatise on Jewish Sacrifices," and a dissertation on the "Lawfulness of Eating Blood." He also prepared a "Treatise on Logarithms," which was not printed. In the

last year of his life he sank into a condition of partial imbecility.

TAYLOR, GEORGE, one of the signers of the declaration of independence, born in Ireland in 1716, died in Easton, Penn., Feb. 23, 1781. He received a good education, but disliking the medical profession, for which he was destined, came to America as a "redemptioner," and on his arrival bound himself for a term of years to an iron manufacturer at Durham, Penn., and was at first employed in menial occupations. His education and intelligence being discovered, his employer made him his clerk, and after his death Taylor married his widow and became master of the establishment. He was elected to the provincial assembly in 1764, and was one of the committee to call a general congress and to instruct the delegates. He continued a member of the provincial assembly till 1770, when he was made a judge of the county court and colonel of militia. In Oct. 1775, he was again elected to the provincial assembly, and was active in the promotion of revolutionary measures. The action of some of the members of the continental congress in the summer of the next year, in refusing their assent to the declaration of independence, led to the election of new members on July 20, 1776, of whom Mr. Taylor was one. He signed the declaration on Aug. 2, subsequently negotiated a treaty with several of the Indian tribes on behalf of the United States, and in March, 1777, retired from congress, and did not again return to public life.

TAYLOR, HENRY, an English author, born in the early part of the 19th century. In 1824 he entered the colonial office, where he is now the second senior clerk. His writings, produced principally between 1827 and 1850, comprise dramas, poems, and essays. He is chiefly known by two dramas in blank verse, "Philip van Artevalde" (1834) and "Edwin the Fair," which have been aptly described as illustrations of the form "we might expect the written drama naturally to assume, if it were to revive in the 19th century, and maintain itself as a branch of literature apart from the stage." His remaining works include "The Eve of the Conquest, and other Poems" (1847); "Notes from Life, in Six Essays" (1848); "Notes from Books, in Four Essays" (1849); and "The Virgin Widow" (1850), a play in 5 acts, chiefly in verse. In 1836 he published "The Statesman," embodying much of his experience of public life.

TAYLOR, ISAAC, an English author, born at Lavenham, Suffolk, Aug. 17, 1787. His father, Isaac Taylor, originally a line engraver in London, became minister of dissenting congregations in Colchester and Ongar, and wrote several popular books for children. His mother, Ann Taylor, also wrote "Maternal Solitude" and other educational works. He was privately and carefully educated, with reference in turn to the dissenting pulpit, the bar, and to art as a profession, but was led by his tastes to the pursuits of literature and scholarship. He has lived in studious retirement at Stanford Rivers,

Essex, devoting himself to the education of his children at home and to the composition of important works on philosophical and religious questions. Although a layman, he occasionally preaches on Sunday. His first publications were: "Elements of Thought" (1822), in which he showed himself a disciple of the Scotch metaphysical school; "History of the Transmission of Ancient Books to Modern Times" (1827), an account particularly of the means by which the authenticity of the Holy Scriptures is ascertained; and "The Process of Historical Proof" (1828), also written in defence of the genuineness of the documentary evidence of Christianity. In 1829 appeared anonymously the "Natural History of Enthusiasm," his most popular work, which pictures in glowing language and with unsectarian zeal an era of revived faith and ecclesiastical union, and which, notwithstanding its elaborately grandiloquent style, was received with special favor by the religious public at the time when the excitement connected with Edward Irving was at its height. It was the first of a series of essays which he meditated on fanaticism, superstition, credulity, the corruption of morals, and scepticism, in which all the principal phases of abnormal religious development should be treated. Of these only the essay on "Fanaticism" (1843) was written, the author having been diverted from his plan by the appearance of the Oxford "Tracts for the Times." He published a series of tracts in reply to those of Dr. Pusey and his associates, which were collected under the title of "Ancient Christianity" (2 vols., 1839-'43). He wrote with similar intent a work on "Spiritual Despotism" (1835), characterized by Sir James Stephen as "the most original, comprehensive, and profound contribution which any living writer in England has made to the science of ecclesiastical polity." His "Physical Theory of Another Life" (1836), in form a speculative treatise, is substantially a narrative of the scenes and incidents of immortality, illustrated from both sacred and profane writers. His most important later publications are: "Loyola and Jesuitism" (1849), and "Wesley and Methodism" (1851), in which he reviews two of the principal modern movements in the Roman Catholic and Protestant churches; "The Restoration of Belief" (1853), an examination of recent sceptical tendencies and results; "The World of Mind" (1857), the aim of which was to set forth "first, what is common to all orders of living beings, and then what is peculiar to the human mind, and which is the ground of its immeasurable superiority;" and "The Spirit of the Hebrew Poetry" (1861), in which he argues that David and Isaiah are the indispensable guides of theistic thought, and that all departure from the theological phraseology of the Hebrew poets is almost always a step toward atheism. He is also the author of several less speculative didactic and devotional volumes, entitled "Home Education" (1838), "Lectures on Spiritual Christianity" (1841), and "Saturday Even-

ing" (1842), and has contributed many essays to reviews.—His sisters, ANN TAYLOR (Mrs. Gilbert) and JANE TAYLOR (1788–1824), wrote jointly several juvenile books which had remarkable success, as "Hymns for Infant Minds" and "Original Poems." The latter also wrote "Essays in Rhyme," a tale entitled "Display," and "Contributions of Q. Q."

TAYLOR, ISIDORE SÉVERIN JUSTIN, baron, a French traveller and author, born in Brussels, Aug. 15, 1789. He studied design under the painter Suvé, and had commenced the life of a *littérateur* and artist when he was enrolled in the French conscription of 1811, but obtained his discharge and made a tour of artistic exploration in Flanders, Germany, and Italy. Returning to France in the last days of the empire, he served several years in the army, rising to the position of major and aide-de-camp of Gen. Dorsey. He then resigned and made excursions to Italy, Greece, European Turkey, Asia Minor, Syria, Egypt, and the African coasts, bringing thence rich collections in archaeology or objects of curiosity, which he placed in the galleries of Versailles, the Louvre, and the various museums of Paris. He exerted himself also to procure from the French chambers the restoration of the principal monuments of the middle ages in France; in 1824 was made royal commissary of the *comédie Française*, and introduced great improvements in scenery and in the character of the operas performed; and at the direction of the government twice visited Egypt, and negotiated the transfer to France of the obelisks of Luxor and the other rare Egyptian antiquities of the Louvre museum. Louis Philippe after his accession confided to him several important artistic missions. Baron Taylor has been very active also in the organization of societies for the benefit of artists and men of letters, of several of which he is perpetual president. In connection with C. Nodier and De Oaillien, he edited *Voyages pittoresques et romantiques dans l'ancienne France* (fol., 1820–'54), a work still incomplete, in the illustration of which several of the most eminent artists in France have assisted; *Voyage pittoresque en Espagne, en Portugal et sur la côte d'Afrique de Tanger à Tétouan* (4to., 1826 et seq.); *La Syrie, l'Égypte, la Palestine et la Judée* (4to., 1837 et seq.); *Pèlerinage à Jérusalem* (1841); and *Voyage en Suisse, en Italie, en Sicile, en Angleterre, en Écosse, en Allemagne, en Grèce, &c.* (1848). While in the army he also published 5 dramas (1815–'22).

TAYLOR, JEREMY, D.D., an English theologian, born in Cambridge in 1618, died at Lisburn, Ireland, Aug. 13, 1687. His father was a barber and surgeon. The son was educated at the grammar school in Cambridge, and at the age of 18 entered Caius college as a sizar, or poor scholar. In 1638 he received the degree of M.A., having distinguished himself by his proficiency in theological studies. Having attracted the attention of Archbishop Laud, he received through his aid a fellowship in All

Souls' college in Oxford, and the rectory of Uppingham in Rutland. His marriage in May, 1639, compelled him to relinquish his fellowship, and he remained in the quiet discharge of his pastoral duties until the troubles in the state drew him prominently into notice. In these political difficulties he took sides with the royalists, became a favorite with Charles I., and secured the degree of D.D. by a defence of episcopacy which he wrote at the king's request. For a time, as chaplain to the king, Taylor followed the fortunes of his master, losing by his devotion his living in the church, suffering imprisonment, and compelled at last to seek refuge in the parish of Llanfihangel, Caermarthenshire. Here, with William Nicholson, afterward bishop of Gloucester, and William Wyatt, afterward prebendary of Lincoln, Taylor for some time taught school. During his residence in Wales a large part of his sermons were composed, and several of his most elaborate works, among others his "Discourse on the Liberty of Prophesying," on "Holy Living and Dying," and the "Life of Christ." In these compositions his mild and tolerant spirit appears, as well as his aversion to controversy. In 1654, however, he ventured into the field of debate, as the opponent of transubstantiation and as the advocate of episcopacy. A double imprisonment was the result of this polemic zeal, and the loss of much of his second wife's fortune. Added to these troubles was the annoying suspicion of heresy concerning original sin, which was excited by his work on "Repentance." In 1658 he was confined in the tower of London, through the act of his publisher in prefixing to the "Collection of Offices" an engraving of a kneeling Christ. After his release he obtained the place of lecturer at Lisburn in Ireland, where he was removed in some degree from the enmity of the Puritan party. Yet even here he was closely watched, and was more than once in danger of arrest as an enemy to the state. After the death of Cromwell, Taylor returned to London, where he was received with honor as the defender of monarchy and the church, and was soon appointed by Charles II., to whom he had dedicated his "Ductor Dubitantium," to the bishopric of Down and Connor in Ireland, to which that of Dromore was soon added, and a member of the Irish privy council; and he was also elected vice-chancellor of the Dublin university. In the administration of his episcopal duties Taylor found great difficulty, from the confusion which the civil wars had wrought in the social condition and the religious life of the Irish people; and though he labored with unwearied fidelity, as pastor, as bishop, and as privy councillor, his episcopal life cannot be called successful.—As a writer of sermons, Jeremy Taylor has by general consent the highest rank among the writers of the English church. The characteristics of his style are: exuberant beauty of diction, both in the choice of words and the flow of the sentences; redundant

illustration from natural scenery, from the customs of life, from science, from history, and from Scripture; great fondness for metaphor; accuracy of method in statement and in division; prolixity, running into almost endless digressions and reveries; with a prevailing moderation, dignity, and majesty of tone. His doctrines were those of moderate orthodoxy. He is the advocate of toleration, of freedom of thought, of charity, and of practical religion as of more worth than dogmatic strictness. His private life was free from any blemish, and even his foes honored his virtue. The works of Taylor have been published in many forms, sometimes separately, and sometimes in complete editions, as in that of Bishop Heber (15 vols., 1823). The most important are the "Holy Living and Dying," a very minute and practical treatise concerning all the routine of the Christian life; the "Life and Death of Jesus Christ," a treatise curious for its quaint and endless erudition, which is still very popular; the "Ductor Dubitantium," which deals with difficult points and cases of conscience; the "Liberty of Prophecy," which is the broadest and most catholic of all his treatises; and the "Dissuasive from Popery," an effort to convert the Irish people to the church of England. The life of Taylor has been written best by Bishop Heber, as the preface to his edition of Taylor's works, and by Willmot (London, 1846).

TAYLOR, JOHN, an English author, called "the water poet," born in Gloucester in 1580, died in London in 1654. He was educated at the free school of Gloucester, and subsequently was apprenticed to a London waterman, an occupation which he followed during the greater part of his life. He also held some position at the tower of London, and kept a public house in Phoenix lane, Long Acre. His publications, in prose and in verse, amounting to upward of 80, have little literary merit, but are of value as illustrations of opinions and manners during the first half of the 17th century. Two of the most curious of his prose works are devoted to descriptions of a journey on foot to Scotland in 1618, and of another, made principally in a boat, from London to Hereford in 1641. He was a staunch loyalist, and when Charles I. was beheaded hung up over his hostel the sign of the "Mourning Crown." His title of "water poet" was self-conferred.

TAYLOR, JOHN, D.D., an English dissenting minister, born near Lancaster in 1674, died at Warrington, March 5, 1761. He was educated at Whitehaven, and settled for 18 years at Kirkstead in Lincolnshire, where he taught a grammar school beside supplying the small congregation there. In 1738 he was chosen pastor of a Presbyterian congregation at Norwich, where he preached for 24 years, and avowed anti-Trinitarian sentiments. In 1757 he became principal of the dissenting academy at Warrington, but met with much opposition. His principal published works are: "An He-

brew English Concordance" (2 vols. fol.); "A Paraphrase on the Epistle to the Romans;" "The Scripture Doctrine of Original Sin;" "The Scripture Doctrine of the Atonement;" "A Sketch of Moral Philosophy;" and "A Scheme of Scripture Divinity," published after his death by his son.

TAYLOR, JOHN, an English author and classical scholar, born in Shrewsbury in 1703, died in Cambridge, April 4, 1766. He was educated at Shrewsbury grammar school and at St. John's college, Cambridge, of which he became a fellow in 1730. Subsequently he became university librarian and registrar at Cambridge, where the greater part of his life was passed. His first publication of importance was an edition of the orations and fragments of Lysias (4to., London, 1739), evincing a remarkably intimate knowledge of the Attic law. In 1741 he was admitted an advocate in doctors' commons, although it does not appear that he ever practised as a civilian; and in 1743 he produced a dissertation in Latin on the Sandwich marble and an edition of two orations by Demosthenes and Lysurgus. Several years later he took orders, and in 1757 was appointed canon residentiary of St. Paul's. In 1755 appeared his most important work, "Elements of Civil Law," of which a 2d edition was published in 1769, and an abridgment in 1798 under the title of "A Summary of the Roman Law." During the latter part of his life he was engaged upon an edition of the Greek orators, to comprise 5 volumes, of which the 3d, containing the 10 orations of Demosthenes, appeared in 1748, and the 2d, containing the controversial orations of Demosthenes and Æschines, together with the epistles ascribed to the latter, in 1757. The remainder of the work was left incomplete at his death.

TAYLOR, NATHANIEL WILLIAM, D.D., an American clergyman, born in New Milford, Conn., June 23, 1786, died in New Haven, March 10, 1858. He was graduated at Yale college in 1807, and then devoted 5 years to the study of theology, mainly under the guidance of President Dwight, in whose family he resided for two years as the president's amanuensis. In 1812 he was ordained pastor of the first church (Congregational) in New Haven, as the successor of Moses Stuart. As a preacher Dr. Taylor soon gained a wide reputation, both for the clearness and force of his reasoning in doctrinal discussions, and for the fervor and pathos of his practical appeals. When his mind was wrought up to its highest tone, his sermons were characterized as "logic on fire." In 1822 he was called to the Dwight professorship of didactic theology, then just established in Yale college. In this office he continued until his death, a period of 36 years, giving instruction to nearly 700 students in course of preparation for the ministry. While yet a pastor, Dr. Taylor had shown his aptitude for theological discussion, in a series of articles upon the Unitarian controversy, which he contributed to the

"Monthly Christian Spectator." He had also in his sermons laid out the groundwork of that theodicy which, in his course of lectures on "The Moral Government of God," became afterward the great thought and labor of his life. The struggles of his own mind with philosophical doubts upon the truths of revealed religion, led him to give special attention to the study of natural theology, and of mental and moral science, as preparatory to the investigation of the Bible as a revelation. In such studies he exhibited an ardor in the pursuit of truth, an honesty of conviction, an independence in thinking, and a courage and candor in argument, which commanded respect and admiration, even where his conclusions provoked dissent. These qualities gave him a rare magnetic power over the minds of young men. In theology, Dr. Taylor was in the main a disciple of Edwards and Dwight, adopting the Calvinistic theory as modified by the Edwardean school. In 1828 he preached at New Haven the *concio ad clerum*, in which he set forth views upon human depravity and other related doctrines which provoked much controversy in New England, and caused him to be widely denounced for heresy. For several years he maintained a vigorous discussion of these and similar topics, through the quarterly "Christian Spectator," sometimes writing with a marked individuality of style, sometimes anonymously reviewing both himself and his opponents. Dr. Taylor insisted much upon the freedom of the will and the responsibility of the individual man; he held that, while depravity is universal in the race, it is not to be ascribed to any property, propensity, or disposition of the soul prior to actual transgression, as sinful in itself, or as the necessary cause of sin, nor to a sinful nature corrupted in or derived from Adam. He traced sin to the constitutional propensity of man for natural good, as perverted by his own moral agency; thus he maintained moral obligation unimpaired. At the same time, by harmonizing certainty with freedom, in the sphere of moral action, he also maintained the supremacy of the divine government in the spiritual as in the natural world. Though his views may have hereafter less prominence as a system than when they were urged and defended by his own resolute will, his earnest logic, and his fervid eloquence, yet they have separately incorporated themselves so widely with the preaching of recent times, that they have silently modified, and, as it is claimed, in the true sense rationalized the Calvinistic theology, without appearing to revolutionize it. Dr. Taylor was always averse to publication; and with the exception of a few occasional sermons, and the controversial articles above referred to, he committed nothing to the press during his long life. Since his death 4 8vo. volumes of his works have been published: one a volume of practical sermons, another a volume of essays and discourses upon the more perplexing and controverted topics

of revealed theology, and the remaining two his argument upon the moral government of God. The system of mental philosophy which he so carefully elaborated, and which was his special delight, has not yet been published.

TAYLOR, RICHARD, an English printer and naturalist, born in Norwich, May 18, 1781, died in Richmond, Dec. 1, 1858. While serving an apprenticeship to a printer in London, he studied the classics and the mediæval Latin and Italian authors, and also the Flemish, Anglo-Saxon, and several of the kindred Teutonic dialects. In 1803 he established himself in business with his father as a printer, and his press soon became the medium through which nearly all the more important works in scientific natural history were published. The beautiful editions of the classics which also issued from it were long celebrated in England. In 1807 he became a fellow of the Linnæan society, and in 1810 was elected its under secretary, an office which he held nearly half a century. He also attached himself from the commencement to the "British Association for the Advancement of Science." In 1822 he became a joint editor of the "Philosophical Magazine," with which he was connected until his death, and in 1838 he established the "Annals of Natural History." His own literary labors, which were principally in the field of biblical and philological research, comprise an edition of Tooke's "Diversions of Purley" (London, 1829 and 1840), enriched with notes; Warton's "History of English Poetry" (London, 1840), in the reediting of which he took the chief part; "Taylor's Scientific Memoirs," a series of papers chiefly translated, &c. He warmly promoted the establishment of University college and the university of London.

TAYLOR, RICHARD COWLING, an English geologist, born in Hinton, Suffolk, Jan. 18, 1789, died in Philadelphia, Penn., Oct. 26, 1851. He was educated as a mining engineer and geologist, partly under the auspices of William Smith, the "father of British geology," and in the early part of his career was employed on the ordnance survey of England. Subsequently he was engaged for many years in investigating and reporting upon mining properties in various parts of England, including that of the British iron company in Wales, his plaster model of which received the gold Isis medal of the society of arts. In 1830 he removed to the United States, and, after surveying the Blossburg coal region in Pennsylvania, devoted 3 years to the exploration of the coal and iron veins of Dauphin co. in the same state, on which he published an elaborate report with maps. For a number of years he was occupied with similar undertakings in the United States, and also made surveys of mining lands in Cuba and the British provinces. In the course of his labors he made careful notes of the chief facts connected with general geology and paleontology, the results of which were published in the "Transactions" of the principal scientific

bodies of England and America. The work, however, on which his reputation rests is his "Statistics of Coal" (8vo., Philadelphia, 1848), which had engaged him for many years, and which was regarded as the standard authority on the distribution, production, and consumption of fossil fuel. Beside his proficiency in economic geology, in which he stood preëminent, he was well informed in theoretic geology, and was the first to refer the old red sandstone underlying the Pennsylvania coal fields to its true position, corresponding with its place in the series of European rocks. During his residence in England he gave much attention to archaeology, and published in 1831 an "Index Monasticus, in the Ancient Kingdom of Anglia" (fol.), followed by a very complete "General Index to Dugdale's Monasticon Anglicanum" (fol., 1830).

TAYLOR, STEPHEN WILLIAM, LL.D., an American educator, born in Adams, Berkshire co., Mass., Oct. 23, 1791, died at Hamilton, Madison co., N. Y., Jan. 7, 1856. He was graduated at Hamilton college, N. Y., in 1817, and took charge of the Black river academy at Lowville, Lewis co., where he remained for 14 years. In 1831 he resigned and became the teacher of a family school, and in 1834 was invited to take charge of the preparatory department of the "Hamilton Institution," now Madison university. In 1838 he was elected to the chair of mathematics and natural philosophy, which he resigned in 1845, and in the following winter removed into Pennsylvania and aided in the establishment of the university at Lewisburg, of which he was chosen the first president. At the end of 5 years (1851), the institution being placed in a flourishing condition, he resigned, and in the same year was offered the presidency of Madison university, then in a state of great depression from the efforts to transfer the collegiate department to Rochester, and the removal of a majority of its faculty and board to that city, although the supreme court had decided that Madison university must remain at Hamilton. He entered upon his duties in the autumn of 1851, and within 3 years the university was stronger in resources and the number of its students than at any previous time. A historical sketch of Madison university, several inaugural and baccalaureate discourses, and a series of essays on the theory of education published in the "Christian Chronicle," Philadelphia, are all that remain of his published works. He had partially completed at the time of his death an elaborate work on education.

TAYLOR, THOMAS, an English scholar and translator, surnamed the "Platonist," born in London, May 15, 1758, died at Walworth, Nov. 1, 1835. He studied the classics, mathematics, and chemistry, but was obliged to relinquish his design of entering a university, and became a clerk in a banking house. Having been appointed assistant secretary of the society for the encouragement of arts, manufactures, and

commerce, he resolved to attempt an English version of all the works of Aristotle and Plato and those of the Neo-Platonists. The duke of Norfolk and others defrayed the expense of the publication of many of these, but Mr. Taylor received little or no profit from them. In this way he issued, in the course of 40 years, translations of part or the whole of Ocellus, the hymns of Orpheus, the complete works of Plato in 5 vols. 4to., Proclus, the emperor Julian, Pausanias, Plotinus, Apuleius, Aristotle, Maximus Tyrius, Demophilus, Iamblichus, Hierocles, Porphyry, Celsus, Olympiodorus, and the "Chaldean Oracles." Beside these he published works on geometry and arithmetic, on the Eleusinian and Bacchic mysteries, on "The Rights of Brutes" (in ridicule of Paine's "Rights of Man"), "Miscellanies in Prose and Verse," &c. His works amounted to 55 vols. 8vo. or 4to.

TAYLOR, TOM, an English author, born in Sunderland, Durham, in 1817. He was educated at the Grange school of his native town, passed some time at the university of Glasgow, and was graduated at Trinity college, Cambridge, of which he became a fellow. After filling for a few years the chair of English literature in University college, London, he was in 1845 called to the bar, and went the northern circuit, until his appointment in 1850 as assistant secretary to the board of health, of which in 1854 he became secretary. Since 1858 he has held the position of secretary to the local government act office. He was a frequent contributor to the early volumes of "Punch," and is favorably known as the author of numerous dramatic pieces, among the most successful of which have been "Still Waters Run Deep," "The Unequal Match," and "The Overland Route." Of more pretension and value than these are his biography of Benjamin Robert Haydon, prepared from the journals of the artist, and his editorial preface and continuation to the "Autobiography of Charles Robert Leslie." His contributions to the periodical press have been numerous.

TAYLOR, WILLIAM, an English author and translator, born in Norwich in 1765, died there in March, 1836. He completed his education in France, Italy, and Germany, returned to Norwich in 1788, and soon began to write for periodicals and translate from German writers. In 1802 he became editor of the "Norwich Iris," a weekly journal, which he continued for two years. Among his publications are translations of Bürger's "Lenore" and Lessing's "Nathan the Wise," a collection of essays on English synonyms, and critical essays on the German poets, with translations, entitled "Survey of German Poetry" (1830). His "Life and Writings," including his correspondence with Southey, was published in 1848, with a memoir by J. W. Robberds (2 vols. 8vo.).

TAYLOR, WILLIAM COOKE, LL.D., an Irish author, born in Youghal, April 16, 1800, died in Dublin, Sept. 12, 1849. He was educated at the university of Dublin, and commenced con-

tributing to the periodical press at an early age. He went to London about 1828, and till his death was constantly engaged in literary labor. His chief works are: "Historical Miscellany" (1829); "History of France and Normandy" (1830); manuals of ancient and modern history; "Natural History of Society" (2 vols.); "History of Mohammedanism;" "History of Christianity;" "History of the Civil Wars in Ireland;" "History of British India;" "Life and Times of Sir Robert Peel" (8 vols.); "Revolutions and Remarkable Conspiracies in Europe" (8 vols.); "Romantic Biography;" "The Bible Illustrated from Egyptian Monuments;" "History of Popery;" and the "History of the House of Orleans," which was his last work. In 1846 he was employed by the British government to inquire into the system of education on the continent, and at the time of his death was about to be appointed superintendent of national education in Ireland.

TAYLOR, ZACHARY, the 12th president of the United States, born in Orange co., Va., Nov. 24, 1784, died in Washington, D. C., July 9, 1850. His father, Col. Richard Taylor, was a Virginian of a distinguished family, who served with zeal and courage throughout the revolutionary war, and subsequently removed to Kentucky, where he was one of the first settlers of Louisville, in the neighborhood of which city he had an extensive plantation. Zachary was but a few months old at the time of his father's emigration from Virginia; and as Kentucky during his infancy and early boyhood was thinly peopled and greatly harassed by the Indians, his means of education were very limited, and were confined to the simplest rudiments of learning. Until his 24th year he was engaged in the labors of the plantation; but his brother Hancock, a lieutenant in the U. S. army, having died in 1808, through the influence of Madison, then secretary of state, who was a relative of the Taylor family, the vacant commission was assigned to Zachary, and he became first lieutenant in the 7th regiment of infantry. He was made a captain in Nov. 1810, and two years later, after the declaration of war against Great Britain, was placed in command of Fort Harrison, a blockhouse and stockade on the Wabash river, about 50 miles above Vincennes. This place was one of the most advanced posts of the United States on the Indian frontier, and was the first object of attack by the tribes whom Tecumseh had stirred up to war against the Americans. Early in September it was invested by a large force of Indians, who, after a futile attempt to outwit the young captain by professions of peace, made a furious night assault, and succeeded in setting fire to the lower buildings of the fort. Taylor had but 60 men, of whom two thirds were ill with fever. He maintained the defence, however, with skill and steadiness, and after a sharp conflict of several hours extinguished the flames and repulsed the savage assailants with such severe loss that at daybreak

they abandoned the siege. For his conduct on this occasion he received from the president the rank of major by brevet, the first instance in the service of this species of promotion. A few months later he took part in a successful expedition led by Gen. Hopkins against the Indian villages, and from that time to the close of the war was actively engaged in service on the N. W. frontier. In 1814 he attained the full rank of major, and commanded an expedition against the British and Indians on Rock river, during which he fought an indecisive action with a superior force of the enemy strongly posted at the mouth of the river. On the restoration of peace in 1815, congress reduced the army and annulled many of the promotions made during the war. By this means Taylor was reduced to the rank of captain, and in consequence resigned his commission and retired to his plantation near Louisville. The influence of his friends, however, soon procured his reinstatement as major, and he was employed for several years alternately on the N. W. frontier and in the south, where in 1822 he built Fort Jesup. In 1826 he was a member of a board of officers convened by the secretary of war to consider and prepare a system for the organization and improvement of the militia of the United States. A report drawn by Gen. Scott was adopted on Taylor's motion, and was approved in congress, but never carried into effect. In 1819 Taylor had received a commission as lieutenant-colonel, and in 1832 he was promoted to the rank of colonel. In the latter year he was engaged in the Black Hawk war, and Black Hawk after his capture was placed in his charge to be conveyed a prisoner to Jefferson barracks. After the war Taylor was ordered to Prairie du Chien, where he took command of Fort Crawford, a work which had been erected under his superintendence. In 1836 he was ordered to Florida, where the war with the Seminoles was then going on without much prospect of a speedy termination. On Dec. 25, 1837, he defeated the Indians in the battle of Okechobee, one of the most desperate and hotly contested in the annals of our warfare with the red men, and which had a decisive effect upon the duration of the struggle, the Seminoles never again rallying in sufficient force to be formidable to the whites. Taylor was rewarded for this affair by promotion to the rank of brigadier-general by brevet, and in April, 1838, he was made commander-in-chief in Florida in place of Gen. Jesup. This post he held till 1840, when he was relieved from it at his own request, and was immediately appointed to the command of the first department of the army in the south-west, comprehending the states of Alabama, Mississippi, Arkansas, and Louisiana. He purchased at this time an estate at Baton Rouge on the banks of the Mississippi, to which he removed his family from Kentucky. On March 1, 1845, congress passed the joint resolution annexing Texas, and on May 28 Mr. Marcy, the secretary

of war, sent a confidential letter to Gen. Taylor, instructing him to hold the troops under his command in readiness to defend Texas in case of an invasion from Mexico. He demanded more explicit instructions, and in reply was directed generally to be governed by circumstances, to avoid all aggressive measures, and to hold his army ready to protect the Texan territory "to the extent that it had been occupied by the people of Texas." The Rio Grande was indicated by the secretary as the boundary of Texas, though the Mexicans maintained that Texas never extended west of the Nueces. Corpus Christi, on Aransas bay, near the mouth of the Nueces, was pointed out as the best point for concentrating the U. S. forces; and accordingly in July, 1845, Taylor embarked at New Orleans with 1,500 troops, and in the beginning of August encamped with them at Corpus Christi, where he was followed by reinforcements, so that in November his forces amounted to about 4,000 men. He remained for several months, during which his conduct under the most embarrassing circumstances was marked by great prudence and discretion. The administration desired to bring the Mexican question to a crisis, without, if possible, incurring the responsibility of beginning a war. Indirectly, therefore, it endeavored to induce Gen. Taylor to advance his forces into the disputed territory; but the wary old soldier disregarded all hints to that effect, and would not move till explicitly ordered to do so by the president. Positive instructions were at length sent, and on March 8, 1846, the army began its march toward the Rio Grande, and on the 28th reached the banks of that river opposite Matamoras. Here it encamped and erected Fort Brown, which commanded Matamoras, where the Mexicans were also throwing up batteries and redoubts. On April 12 Gen. Ampudia, the Mexican commander, addressed a note to Gen. Taylor requiring him within 24 hours to break up his camp and retire beyond the Nueces, "while our governments are regulating the pending question in relation to Texas," and informing him that his non-compliance would be regarded by the Mexicans as equivalent to a declaration of war. Gen. Taylor replied that he was acting under instructions which did not permit him to return to the Nueces, and that if the Mexicans saw fit to commence hostilities he should not avoid the conflict. Ampudia was soon after superseded as Mexican commander-in-chief by Arista, who early in May crossed the Rio Grande with a force of 6,000 men, and on the 8th of that month attacked and was defeated by Gen. Taylor with 2,300 men at Palo Alto, a few miles from Matamoras. (See PALO ALTO.) The Mexicans retreated to Resaca de la Palma, where they took up a strong position, and on the following day again gave battle to the Americans, who after a severe contest routed them with great loss and drove them across the Rio Grande. The total loss of the Mexi-

cans in these battles amounted to about 1,000 men. In his report to the government Gen. Taylor said: "Our victory has been decisive. A small force has overcome immense odds of the best troops that Mexico can furnish—veteran regiments, perfectly equipped and appointed. Eight pieces of artillery, several colors and standards, a great number of prisoners, including 14 officers, and a large amount of baggage and public property, have fallen into our hands." The first intelligence of the outbreak of hostilities on the Rio Grande called forth a special message from the president (May 11), in which he declared that the Mexican government had "at last invaded our territory, and shed the blood of our fellow citizens on our own soil." Two days later congress declared that "by the act of the republic of Mexico war exists between that government and the United States," and at the same time authorized the president to accept the services of 50,000 volunteers. Meanwhile Taylor, who had been promoted to the rank of major-general as a reward for his victories, took possession of Matamoras on May 18 without opposition, and remained there awaiting reinforcements and organizing his forces till September, when he marched against Monterey, which he reached Sept. 9 with a force of 6,625 men, mostly volunteers. The place was defended by Gen. Ampudia with about 10,000 regular troops. On the 19th Gen. Taylor ordered an assault, and after 8 days' desperate fighting Gen. Ampudia capitulated on the 24th. (See MONTEREY.) Taylor made Monterey his headquarters, but occupied with a strong detachment the city of Saltillo, the capital of the state of Coahuila. He was diligently making preparations for an advance with an adequate army upon San Luis Potosi, an important city 300 miles south of Saltillo, when he received in December a letter from Gen. Scott, the commander-in-chief, who was then at New York, informing him that, as he was about to lead an expedition against Vera Cruz, "I shall be obliged to take from you most of the gallant officers and men, regulars and volunteers, whom you have so long and so nobly commanded." His troops were accordingly taken from him, as some of his friends alleged, from motives of jealousy on the part of the democratic leaders who controlled the administration, it being well understood that he was a whig in politics; and he was left to stand on the defensive with only 5,000 men, of whom but 500 were regulars, the rest being volunteers who had never seen a battle. He received intelligence that Santa Anna, the ablest of the Mexican generals, had concentrated at San Luis Potosi the flower of the Mexican army to the number of 21,000 veteran troops, and was moving rapidly to attack him in the valley of the Rio Grande. After carefully examining the ground, Taylor on Feb. 21, 1847, took a position at Buena Vista, a mountain pass 9 miles from Saltillo, and awaited the approach of the Mexicans,

who made their appearance on the following day, and notwithstanding their immense superiority of numbers were signally defeated. (See *Buena Vista*.) Santa Anna retreated with his disheartened followers to San Luis Potosi, and during the rest of the war the frontier of the Rio Grande and the valley of that river remained in quiet possession of the Americans. For a period of several days before and after the battle all communication between the United States and Gen. Taylor's army had been cut off by detachments of Mexican cavalry, and great anxiety prevailed throughout the country as to the result of the encounter between forces so unequal. Rumors came from the Rio Grande that Taylor had been overpowered by the Mexicans and all his troops killed or captured. In consequence of this painful suspense the true tidings of the achievement of a splendid and decisive victory over very superior numbers were received with enthusiastic satisfaction, and the reputation and popularity of Gen. Taylor, already very great, attained the highest pitch. The modest and dignified tone of the despatches in which he announced to the government his victories largely contributed to heighten the public esteem for his character, and on his return home in Nov. 1847, "Old Rough and Ready," as his soldiers familiarly called him, was greeted everywhere by the warmest demonstrations of popular applause. This popularity naturally led to propositions to nominate him as a candidate for the presidency at the approaching election of 1848; and indeed, immediately after the reception of the news of the battles of Palo Alto and Resaca de la Palma, he had been so nominated by popular assemblages at Trenton, N. J., and in the city of New York. These hasty nominations, however, were made by persons of little consideration, and attracted but a small share of the public regard. In March, 1847, overtures were made to Gen. Taylor by some of the leaders of the native American party, to which he replied, April 28, that while the country was involved in war and he was engaged in operations against the enemy he could not acknowledge any ambition beyond that of bestowing all his best exertions toward obtaining an adjustment of our difficulties with Mexico. After his return home, however, he wrote and authorized the publication of several brief letters in which he defined his political position, and from which it appeared that he was, as he himself expressed it, "a whig, but not an ultra whig." In a letter to Peter Sken Smith, Jan. 30, 1848, he said: "I have neither the power nor the desire to dictate to the American people the exact manner in which they should proceed to nominate for the presidency of the United States. If they desire such a result, they must adopt the means best suited, in their opinion, to the consummation of the purpose; and if they think fit to bring me before them for this office, through their legislatures, mass meetings, or

conventions, I cannot object to their designating these bodies as whig, democrat, or native. But in being thus nominated, I must insist on the condition—and my position on this point is immutable—that I shall not be brought forward by them as the candidate of their party, or considered as the exponent of their party doctrines." In a letter to Capt. J. S. Allison, April 23, 1848, he said: "I have consented to the use of my name as a candidate for the presidency. I have frankly avowed my own distrust of my fitness for this high station; but having, at the solicitation of many of my countrymen, taken my position as a candidate, I do not feel at liberty to surrender that position until my friends manifest a wish that I should retire from it. I will then most gladly do so. I have no private purposes to accomplish, no party projects to build up, no enemies to punish—nothing to serve but my country. . . . I am a whig. If elected, I would not be the mere president of a party. I would endeavor to act independently of party domination. I should feel bound to administer the government untrammelled by party schemes. . . . I shall engage in no schemes, no combinations, no intrigues. If the American people have not confidence in me, they ought not to give me their suffrages. If they do not, you know me well enough to believe me when I declare I shall be content. I am too old a soldier to murmur against such high authority." These declarations were satisfactory to a great portion of the people, especially of the whig party; and when the whig national convention met at Philadelphia, June 1, 1848, a considerable number of the delegates were pledged to the support of Gen. Taylor. Strong opposition, however, existed to him on various grounds. The friends of Daniel Webster and of Henry Clay insisted upon the claims of those eminent statesmen upon the whig party, and portrayed the injustice of setting them aside in deference to the mushroom popularity of a mere military chieftain, "an ignorant frontier colonel," as Mr. Webster called him, who had neither experience nor knowledge of civil affairs, and as he himself admitted had paid so little attention to politics as not to have voted for 40 years. It was also alleged that Gen. Taylor could hardly be considered a whig, and was of doubtful orthodoxy on many essential points of the whig political creed. The free-soil whigs further objected that Gen. Taylor was a slaveholder, and was not pledged against the extension of slavery, a question then predominant in American politics. Amid these conflicting views the convention began to ballot for a candidate. The whole number of votes was 280, and 141 were necessary to a choice. On the first ballot Taylor received 111 votes, Clay 97, Scott 43, Webster 22, all others 6; second ballot, Taylor 118, Clay 86, Scott 49, Webster 22; third ballot, Taylor 133, Clay 74, Scott 54, Webster 17; fourth ballot Taylor 171, Clay 35, Scott 60, Webster 14, and Taylor

was declared the candidate. Henry Wilson of Massachusetts and a few other delegates, on this result being announced, withdrew from the convention, and subsequently formed the free-soil party on the basis of opposition to the extension of slavery. They justified their secession from the convention and from the whig party, not only by the fact that Gen. Taylor was a slaveholder and not opposed to the extension of slavery, but also by maintaining that he was not really a whig, and especially that he was so unqualified by natural talent or acquired experience for the office of president, that his nomination was one "not fit to be made," as was subsequently said in a public speech by Mr. Webster, who for a time refused to acquiesce in the action of the convention. After the nomination of Gen. Taylor the whig convention proceeded to ballot for a candidate for the vice-presidency, and on the second ballot Millard Fillmore of New York was nominated. The democratic national convention had already nominated at Baltimore, May 22, 1848, Lewis Cass for the presidency; but a powerful section of the New York democracy, familiarly known as barnburners, refused their support to Mr. Cass, partly because of his pro-slavery position, and partly to punish him and his southern partisans for preventing the nomination of Martin Van Buren by the democratic national convention of 1844, when Mr. Van Buren was set aside for a comparatively obscure politician, Mr. Polk. On Aug. 9, 1848, these free-soil democrats assembled in a great mass and delegate convention at Buffalo, N. Y., together with the free-soil whigs who had rejected the nomination of Gen. Taylor, and the liberty party men who had previously supported James G. Birney as the distinctive anti-slavery candidate for the presidency. A fusion of these parties was effected on the basis of a platform of which opposition to the extension of slavery was the leading principle, and Martin Van Buren was nominated for president and Charles Francis Adams of Massachusetts for vice-president. The election took place in November, and for Taylor and Fillmore 168 electors were chosen to 127 for Cass and Butler, the democratic candidates. The Van Buren and Adams party did not succeed in carrying a single elector, their popular vote being 291,678, while that for Gen. Taylor was 1,362,081, and that for Cass 1,222,455. Gen. Taylor was inaugurated president on Monday, March 5, 1849, and on the following day appointed as his cabinet John M. Clayton of Delaware, secretary of state; William M. Meredith of Pennsylvania, secretary of the treasury; George W. Crawford of Georgia, secretary of war; William B. Preston of Virginia, secretary of the navy; Thomas Ewing of Ohio, secretary of the interior; Jacob Col-lamer of Vermont, postmaster-general; and Beverly Johnson of Maryland, attorney-general. During the summer the president made a tour through the middle states as far as Lake Erie, and was everywhere received with mani-

festations of popular enthusiasm. Notwithstanding, however, his great personal popularity, the numerical preponderance of the democratic party in the country enabled it to elect a sufficient number of members of congress to give the opposition a decided majority not only in the senate but in the house of representatives. In the latter body a few free-soil members elected by the anti-slavery party held the balance of power between the whigs and democrats. On the opening of the 31st congress, Dec. 8, 1849, the house proved to be divided as follows: democrats, 112; whigs, 105; free-soilers, 18. Under these circumstances it was found impracticable to elect a speaker till Dec. 22, when the plurality rule was adopted, and on the 68d ballot Howell Cobb of Georgia, a democrat, was elected. Immediately afterward a vehement struggle commenced with regard to the organization of the new territories, the admission of California as a state, and the question of the boundary between Texas and New Mexico, all of these subjects being connected with the great and absorbing question of the extension of slavery. California had applied for admission into the Union with a constitution excluding slavery, which had been framed by a convention of the people without the usual preliminary authorization from congress. There being at this time an equal number of free and slave states in the Union, the proposition to admit California and thus give the free states a preponderance in the senate excited throughout the South the most violent opposition. At the same time New Mexico and Utah, or Deseret, as it was called by the Mormons who occupied it, were without governments, while the boundary question between New Mexico and Texas was creating great agitation in the southwest, the people of Texas threatening to take possession of the disputed territory by force. President Taylor in his messages to congress recommended, as the easiest way of settling the dispute, that California should be admitted, and that the other territories should form state constitutions to suit themselves, and should be admitted into the Union with or without slavery as their constitutions might prescribe. These recommendations were not acceptable to the slaveholding leaders, many of whom made open threats of secession in case of the admission of California. Scenes of violence occurred in the senate, and great excitement and agitation existed at Washington and throughout the country. Henry Clay in the senate, to settle the controversy, introduced propositions for "an amicable arrangement of all questions in controversy between the free and the slave states growing out of the subject of slavery." These propositions provided for the admission of California as a state; the formation of territorial governments in all the rest of the territory recently acquired from Mexico, without any restriction as to slavery; the determination of the boundary of Texas; the payment of the debt of Texas; declaring against the abolition

of slavery in the district of Columbia; declaring that the slave trade in the district ought to be abolished, but that congress has no right to prohibit or obstruct the slave trade between the states; and lastly that a more stringent fugitive slave law should be passed. (See CLAY, HENRY, vol. v. p. 322.) Mr. Clay's propositions were still the subject in one form or another of exciting debates in congress and of earnest discussion among the people, when on the 4th of July, 1850, Gen. Taylor was seized with bilious fever, of which he died on the 9th at the presidential mansion.—In person Gen. Taylor was of middle stature and stout form, with dark complexion, high forehead, and keen penetrating eyes, with a face more remarkable for intelligence than for elegance, and an expression of much kindness and good nature. His manners and appearance were very plain and simple. As president he fully maintained the popularity which had led to his election, and was personally one of the most esteemed of those who have filled the chief executive office of the country. His administration will be ever memorable as the period in which the antagonism between the free states and the slave states reached a crisis that seriously threatened the Union—a crisis then avoided, however, by a compromise. It was during this administration that the secession party in the South first manifested itself in considerable force outside of the state of South Carolina. To the schemes of this party Gen. Taylor was sternly opposed, and in reply to a delegation of its congressional leaders, who waited upon him with threats of disunion and civil war, he said that if the standard of revolt were raised, he would himself take the field to suppress it at the head of an army of volunteers, and should not for that purpose deem it necessary to call upon a single soldier from the North.

TAZEWELL. I. A S. W. co. of Va., bordering on Ky., drained by the head streams of Clinch and Sandy rivers; area, 1,800 sq. m.; pop. in 1860, 9,920, of whom 1,202 were slaves. Clinch mountain and other ranges traverse the county. The soil of the valleys is very fertile. The productions in 1850 were 285,126 bushels of Indian corn, 125,214 of oats, 21,327 of wheat; and 185,910 lbs. of butter. There were 6 tanneries, 15 churches, a bank, and 654 pupils attending public schools. Capital, Jeffersonville. II. A central co. of Illinois, bounded N. W. by the Illinois river and intersected by the Mackinaw; area, 550 sq. m.; pop. in 1860, 21,471. The surface is level, consisting mostly of prairies, and the soil highly fertile. The productions in 1850 were 1,114,640 bushels of Indian corn, 144,241 of wheat, 146,992 of oats, 9,986 tons of hay, and 186,350 lbs. of butter. There were 8 grist mills, 11 saw mills, 17 churches, 2 newspaper offices, and 2,941 pupils attending public schools. Capital, Tremont.

TOHAD, or TEAD, a lake of Soodan, in central Africa, lying between lat. 12° 30' and 14° 30' N. and long. 18° and 15° E. It is about

150 m. long from N. to S. and 125 wide from E. to W., and has a probable area of 15,000 sq. m., varying greatly however in the dry and the rainy season. Its depth rarely exceeds 15 feet, and many portions of it during the dry season are rather a reedy swamp than a lake; the *inkibul* or open water in the dry season occupies only the central and S. W. part; its elevation above the sea level is 850 feet. The water is fresh and sweet, though that in the marshy pits along the shores is brackish in the dry season from the presence of natron. It has two considerable tributaries, the Komadugu and the Shary, the former flowing from the W., and the latter from the S., but no outlet. The shores abound with rushes and reeds, and the lagoons and shallower portions of the lake are covered with aquatic plants, among which the most conspicuous are the lotus (*Nymphaea lotus*) and a floating plant called by the natives *fanna bellabago* or homeless fanna. A species of antelope, which Barth supposes to be the *antilope Arabica*, feed in large herds on the shores of the lake, and the native cattle thrive on its rich pasturage. The hippopotamus and crocodile wallow in great numbers in the shallow lagoons, and turtles and fish are abundant. The southern banks of the Tchad are flat and low, and are extensively inundated; but the northern are high and woody, and here elephants are found in vast herds. Water fowl are also numerous, principally of the duck tribe. There are extensive islands in the lake, which are densely inhabited by a pagan race called Biddoomahs, distinct from the surrounding Mohammedan tribes. (See BIDDOOMAHS.) The existence of this lake was known to Leo Africanus in the 16th century, but the first Europeans who visited it in more modern times were Denham and Clapperton in 1823, and Barth, Overweg, and Vogel in 1851-'6. Dr. Overweg died on its banks, Sept. 27, 1853.

TOHERNIGOV, a S. W. government of European Russia, province of Ukraine, bounded by Smolensk, Orel, Koorsk, Pultowa, Kiev, Minak, and Mohilev; area, 21,250 sq. m.; pop. in 1856, 1,401,879. The surface, with the exception of the western portion, is flat, and the soil is particularly fertile. It is well watered by numerous streams, the most important of which are the Dnieper, which flows on the W. boundary, and its affluent the Desna, which intersects the government. Horses, horned cattle, and sheep are abundant, and the breeds of the two first are particularly good. Much honey and wax are obtained from bees; and locusts are often very destructive. The manufactures are confined chiefly to articles for domestic use. A large quantity of brandy is distilled. The largest place in the government is Nieshin, a manufacturing town.—TOHERNIGOV, the capital, on the Desna, 60 m. N. N. E. from Kiev, is one of the oldest towns in the Ukraine, and has a large trade; pop. 12,000. It was formerly held by the Tartars and Poles.

TOHIHATCHEF, PETER, a Russian geologist and naturalist, born at Gatchina, near St. Petersburg, in 1812. Early in life he was employed in the Russian bureau of foreign affairs, and between 1841 and 1844 was attached to the embassy at Constantinople. In the latter year he quitted the public service in order to devote himself exclusively to scientific pursuits, and soon after was commissioned by the government to explore the Altai mountains, of which he published an account under the title of *Voyage scientifique dans l'Altai et dans les contrées adjacentes* (4to., Paris, 1846). His next undertaking was the scientific exploration of Asia Minor, which was accomplished, amid great perils and difficulties, in the space of 6 years. His time has since been mainly devoted to the preparation of his elaborate work, *L'Asie Mineure; description physique, statistique et archéologique de cette contrée*, of which only the first two parts, relating to the physical geography, climatology, and botany of the subject, have as yet appeared (2 vols. 8vo., Paris, 1858-'6, with atlas and plates). The remaining portion, treating of geology, statistics, and archæology, are in preparation. The author has also published in the transactions of scientific bodies many minor papers on subjects connected with his studies. He resides in Paris.

TEA (Chinese, *tsa, cha, or tha*), the dried leaves of several plants of the genus *thea*, belonging to the natural order *Ternströmiaceæ*. The plants are evergreen shrubs belonging to the same family as the camellias, and the two principal species of Linnaeus, also recognized by Lindley, *T. bohea* and *T. viridis*, have also been called *camellia bohea* and *C. viridis*. They are now however only regarded as varieties of the *T. sinensis*. The plants are bushy, with numerous leafy branches, and grow to the height of from 3 to 5 feet, and sometimes much higher. The leaves are 2 or 3 inches long and half an inch to an inch broad, of elliptical oblong shape, serrated except at the base, marked with transverse veins, of shining green color, and are supported alternately on short channelled foot-stalks. The flowers are white, of considerable size, and resemble those of the myrtle; they are either solitary, or 2 or 3 together on separate pedicels, at the axils of the leaves; calyx short, green, divided into 5 segments; corolla with 5 to 9 petals cohering at the base; stamens numerous, with yellow anthers; pistil with a 3-parted style; capsules 8-celled and 3-seeded. The two species are distinguished by botanists chiefly by the shape of the leaves. De Candolle admits but one species, with two varieties, viz.: the *viridis*, with "lanceolate flat leaves, 3 times as long as they are broad," and the *bohea*, with "elliptical, oblong, subrugose leaves, twice as long as broad." These specific names have no relation to the kinds of tea known as green and bohea, as both are produced from either one of the plants, as will be explained below. The plants are indigenous in China and Japan, and are said by the

Chinese writers to have been first discovered in the hills of the central provinces, where they are still abundant. No certain allusion to tea is traced back further than the 9th century. Two Arabian travellers, as translated in the work of Renaudot, *Anciennes relations des Indes et de la Chine*, describe it as being in use as a beverage by the Chinese in the latter half of the 9th century. The Japanese, to whom the tea plant is almost as valuable as it is to the Chinese, affirm that the latter obtained it about the year 828 from Corea; but this is not credited. Tea was first made known in Europe by the Portuguese, who imported it early in the 16th century; and in 1589 a notice of it was published in the *Historia Indica* of Giovanni Pietro Maffei, and also by Giovanni Botero. Travellers in China and other eastern countries, in the early part of the 17th century, gave most extravagant accounts of the virtues of tea, which appears to have been in very general use at that time throughout a large portion of Asia. The Persians are described by Adam Olearius (1687) as boiling the leaves till the water acquires a bitterish taste and a blackish color, when they add to it fennel, anise seed, cloves, and sugar; the Hindoos, he adds, put it into seething water. About the same time the peculiar method of preparing it by the Japanese, which is still in practice, was described by Mandelslo of the Danish embassy; this consists in reducing the leaf to powder, and putting this into porcelain cups full of boiling water. The Dutch East India company introduced tea into Europe in the first half of the 17th century, and it was known several years previous to 1657 in England as a choice and very rare article in occasional great entertainments. It had long been the custom in European countries to make use of hot infusions of leaves as beverages, and in England those of the sage were much employed, and are even said to have been carried to China by the Dutch to be there exchanged for the Chinese tea leaf. Tea at that early period was valued at £6 to £10 a pound weight. It was offered for sale in 1657 by Thomas Garway, the founder of the London coffee house, still known as "Garraway's," at prices varying from 15 to 50 shillings a pound. He also sold it, in the infusion, "made according to the directions of the most knowing merchants and travellers into those eastern countries." This appeared in a printed sheet by Garway, entitled "An exact Description of the Growth, Quality, and Virtues of the Tea Leaf." In 1660, by act of parliament, tea, with chocolate and sherbet, was made subject to a tax of 8d. on every gallon made and sold. The article still continued very rare, as in 1664 a present of 2 lbs. 2 oz., costing 40s. a pound, was made to the king by the East India company; and two years afterward another present, also obtained from the continent, was made of 22½ lbs., for which the directors paid 50s. a pound. In 1677 the East India company took the first step toward im-

porting teas, in an order to their agents for teas of the best kind "to the amount of £100." There was received the next year 4,718 lbs., which seems to have glutted the market. The recorded import by the company for 6 years afterward was only 410 lbs.; but some tea appears to have been introduced through other means. About the close of the century the average importation amounted to about 20,000 lbs. a year; in 1708 to over 100,000 lbs., at an average value of about 16s.; and in 1721 it reached 1,000,000 lbs. Thus the tea trade rapidly grew to great importance, and the article being regarded as one of luxury rather than of necessity, it was made the subject of enormous duties, which, while they added largely in the 18th century to the revenues of the kingdom, led to an extensive system of smuggling, and also to adulteration of genuine and fabrication of counterfeit teas. The East India company had the monopoly of the trade until it was thrown open on April 22, 1834, with low duties, ranging from 1s. 6d. to 8s. a pound. The importations of 1833 amounted to 32,057,852 lbs., and those of 1835 to 44,360,550 lbs. In 1859 the receipts were 88,500,000 lbs., which, at the present duty of 1s. 5d. per pound, yielded a revenue of £5,914,000. The extent of the trade in the United States will be noticed at the close of this article.—The range and cultivation of the tea plant is over a large portion of China between lat. 20° and 40° N., extending east over the Japan islands, and stretching west about the 30th parallel to Nepal and the Himalaya. The most important district in China is near the coast from about lat. 25° to 32°, or to Shanghai. The productive districts in China are Fo-kien and Canton for black tea, and Kiang-nan, Kiang-si, and Che-kiang for green. The most important of these are Fo-kien and Kiang-nan. Robert Fortune, the botanical collector to the horticultural society of London, observed that both the black and green teas of the northern districts are obtained from the *T. viridis*, while those of both sorts shipped from Canton are produced from the *T. bohea*. Tea is also an important product in Japan, Tonquin, and Cochin China. The plant is also cultivated in the mountainous parts of Ava. In the mountains which separate China from the Burmese territories the tea plant is indigenous, and abounds especially in Upper Assam, bordering on the province of Turman. Its culture has been encouraged by the government of British India in the N. W. provinces and the Punjab. In Nepal, lat. 27° 43' N., the plant is cultivated at an elevation of 4,784 feet above the bay of Bengal. The tea from these districts sometimes brings in India from \$1.50 to \$1.75 per pound. The Dutch have introduced the culture with considerable success upon the hills of the island of Java. The plant has been introduced into Brazil, and, with the assistance of Chinese laborers, some tea has been produced near Rio Janeiro. The cultivation of tea in the United

States was attempted at Greenville, in the mountainous parts of South Carolina, by the late Dr. Junius Smith, from 1848 to 1852. He imported plants of 5 to 7 years' growth from China, and stocked a small plantation with them in that region, where they were exposed without injury to severe frosts during the winters, and to snow which covered the ground 8 or 9 inches deep. From his experiments it would appear that the climate and soil are very well adapted to the cultivation of the plant; but the want of experienced labor, and the abundance of other more profitable employments, will probably long prevent the culture from attaining any importance in this country. It may perhaps soonest succeed in California, where Chinese laborers can conduct the manipulations, and the processes may be simplified and economized by the introduction of improved apparatus and machinery. But although the high cost of transportation from the interior districts of China to the coast, and the long sea voyage to the United States, are important points in favor of introducing the culture into the United States, there are on the other hand to be considered the extremely low cost of labor in China, which is worth only from \$3 to \$4 per month, and that this is the chief item of expense in the production of tea. Ordinary congou tea in the tea-producing districts is rated at from 6 to 8 taels per picul, or from 8 to 9 cts. per pound. The packing and transportation add to this about 3 cts., and the export duties and charges about 3 cts. more, making the cost to the shippers about 15 cts. So it appears that even with a high protective duty there is little probability that the culture could be made profitable. The districts of southern China are mostly of a mountainous character, and too rocky to be much cultivated. It is not until passing the sterile granitic regions that the more fertile districts devoted to the tea culture are met with further north, near the river Min, in the provinces of Fo-kien and Che-kiang. The lands here spread out into broad plains, some of which are at a lower level than the surface of the rivers and canals which pass through them, but the soil of these is usually a stiff clay, more unproductive than the soil of plains elevated a few feet above the level of the rivers and canals, as is the case with much of the cultivated lands of Shanghai. The tea carefully cultivated upon these plains is known as "garden tea," while that grown upon the more elevated lands is called "hill tea." In several of the provinces very good tea is produced upon hills where the soil is rich. The geological formations in some of the districts are granitic, and in some they consist of silurian slates with red calcareous sandstone, and in the bohea tea lands of Woo-e-shan of clay slate, associated with beds of quartz cut through by dikes and veins of black granite, and overlaid by sandstones and conglomerates composed of quartzose grains and pebbles held together by a calcareous paste. The hillsides in

this region often present nothing green excepting the tea shrubs.—The soil best adapted for the growth of the tea plant is a light loam more or less stony, containing considerable vegetable matter, and which, while retentive of moisture, is at the same time well drained, and sufficiently porous to be permeable to the delicate fibres of the roots. The seeds, gathered in October, are kept in sand till the next spring, when they are sown either in the rows in which they are to grow, or in a bed from which they are afterward transplanted to the tea fields. The seeds are planted 6 or 8 together in holes ranged in rows about 4 feet apart, and as the plants germinate, if the season is dry, they are watered with water in which rice has been washed, and sometimes treated with liquid manure or the dung of silkworms. Water lodging about the roots is apt to destroy the plants, and manure is thought to impair the flavor of the tea. In the winters, if the cold is severe, the young tender shrubs are often protected by a wrapping of straw around them. The first gathering of the leaves does not take place until the second or third year. The young leaf buds are sometimes gathered early in April, for the kind of tea known as pekoe, which is the choicest of black teas. The plants might be seriously injured by the loss of the young buds, but for the copious rains which fall about this season. New leaves soon appear, and these, gathered the last of April or early in May, constitute the most important crop. The third gathering, early in July, furnishes leaves of inferior quality. In some parts of the country a fourth crop is gathered in August or September, of large and old leaves of little value. The duration of the plants is 10 or 12 years, when they are dug up, and replaced by seedlings. The leaves are stripped off rapidly without much care, into baskets of split bamboo, and are carried to the building where, after being sorted, they are subjected to the drying process. The buildings used for this purpose appear to be low sheds more or less open at the sides, and furnished within with rows of pans in stacks of brickwork. The drying is variously conducted according to the quality of the tea, some kinds being exposed to the open air in shallow pans, some being tossed up in the air, and some, too choice for handling, are whirled round in sieves. They are then exposed in the pans to sufficient heat to dispel their moisture without impairing the aroma of the tea, and this is effected by a person tending each pan and keeping the leaves constantly in motion with his hands. A brisk fire of dry wood is kept up under the pans during this roasting process. In a few minutes the leaves become soft and pliable and moist upon the surface. They are then thrown upon a table of split bamboo, and a number of workmen around take them up in their hands and roll them, by which they acquire the curled form common to the commercial tea. As soon as this is done, the leaves are exposed upon a

bamboo screen to the action of the air, when they are again roasted with less heat over a charcoal instead of a wood fire. They are again rolled, and sometimes the processes are again repeated. The final drying is commonly in the pans, of the finest sorts at a very gentle heat over a charcoal fire. The difference between green and black teas is owing to the longer exposure of the latter to the air before the drying, and during the different stages of the drying process. Instead of the leaves being taken directly to the drying pans, they are left, if intended for black tea, spread out sometimes a whole night on bamboo mats, and are afterward tossed about and exposed to the air. The heating and rolling processes may also be repeated as many as 4 times; and the final drying is slowly conducted, a workman opening and stirring the leaves with his hands to afford free passage to the vapors. The effect of this is to induce a partial fermentation and oxidation of the leaves, accompanied with a change of color to black. By rapid drying, with the least exposure to the air, the leaves not only remain green, but they retain more of the active properties of the plant, as appears from the greater effect of green teas upon the nervous system. It is also stated that the difference between green and black teas is owing in part at least to difference of soil, climate, and age of the leaves, the plants furnishing the black teas being grown in hilly and mountainous places, and the green tea shrubs being cultivated on level lands, in soils enriched with manure. Some of the varieties of green tea are produced by sorting a single kind by sifting through sieves of different sizes, and the finer kinds thus separated are sometimes roasted after this 3 or 4 times. Since the great demand for green teas for the United States in 1832 and 1833, the Chinese have been in the habit of artificially coloring inferior or damaged black teas, so as to make them pass for the higher priced green teas, and by similar methods of improving the color of the poorer sorts of green tea. As witnessed by Sir John Davis, the method of coloring consists in first stirring among the leaves, while heated in the pans, a little pulverized yellow turmeric, and then adding a mixture of finely pulverized Prussian blue and gypsum. Indigo and porcelain clay are also used for this purpose. To such an extent is this adopted, that it is believed that all green teas exported from China are glazed or colored; and according to Dr. Hassall, when they are not colored there is little to distinguish green from black tea, the chief difference in color being that the former is sometimes inclined to olive. Some varieties of black teas, as the scented caper or black gunpowder and orange pekoe, are also made to present a peculiarly smooth and glossy appearance by rolling the leaves with pulverized graphite or black lead. None of these fine varieties are ever found in England otherwise than adulterated, but the souchong and congous are generally free from this deception.

The Chinese also employ other methods of adulteration, as intermixing other kinds of leaves with those of the tea plant, such as leaves of the ash, plum, &c. This too is practised chiefly with the green teas; and they even manufacture a spurious article, which they call themselves lie tea, and so brand the chest containing it, made up of the dust of tea and other leaves, and sand, which by means of starch or gum they cause to cohere in little masses; these they paint and color with great skill to imitate either black or green gunpowder tea. Lie tea is also mixed with other teas of low quality, the proportion being certified to by the Chinese merchant who disposes of them. It may be detected by the leaves not unfolding when steeped in boiling water. It was stated in evidence before the parliamentary committee in 1856, that the importations of lie tea into England amounted to £400,000 or £500,000. From other evidence presented to this committee, it would appear that the English vie with the Chinese in the variety and ingenuity of their adulterations of tea. They employ a greater number of foreign leaves and of coloring matters, some of which are much more dangerous from their poisonous qualities than those used by the Chinese. Some of these falsifications may be readily detected by washing away the soluble matters from a sample of the tea exposed to a gentle stream of cold water, and also by burning another sample and comparing the weight of its ash with that of teas of undoubted character. While the ash of genuine teas amounts to from 5 to 6 per cent., that of adulterated teas has been found of various weights up to 45.5 per cent. Another fraudulent practice is to cause teas which have been once used and exhausted of their virtue, to assume again the appearance of fresh tea. This has been carried on in England by collecting the exhausted leaves from hotels and coffee houses, and redrying them, treated with gum water, in establishments devoted to this business. The leaves are then sold to be intermixed with genuine teas, or they are artificially colored and glazed to be sold as green tea. In order to communicate an agreeable scent to tea, the Chinese mix with some kinds the leaves of sweet-scented flowers, such as *chloranthus inconspicuus*, *olea fragrans*, and others. The flowers are dried, powdered, and sprinkled over the tea, or the fresh flowers are arranged in alternate layers with the tea leaves, when both are roasted till the flowers become crisp. In either case they are finally removed by sifting. The tea farms in China seldom produce more than 600 chests of tea each. The crops are bought up by tea merchants, who collect together from different farms enough for 620 or 630 chests, which they mix together, roast again, and then pack in chests for transportation. The next merchant who buys the tea puts upon the chests some mark that is in good repute, and sends them forward to the shipping ports, toward which the transportation through some of the

districts is by men who carry the chests slung one at each end of a bamboo, which rests across the shoulder. But if the tea is of superior quality, a single chest is fastened at the ends of two bamboos, and is thus carried upon the back of a man; the other ends of the bamboos project in front, and are tied together. By placing these ends upon the ground and raising them to a perpendicular position, the cooly is relieved of the weight of the chest as he stops to rest in ascending the steep mountain passes; and wherever he stops he sets the chest in this manner against the wall, never allowing it to be defaced nor the tea injured by the chest touching the ground. From the bohea countries to Canton the transportation is effected by a number of portages alternating with shipments in boats, occupying altogether from 6 weeks to 3 months. From the same region to Shanghai by similar means the distance of 620 miles is accomplished in about 28 days.—The soluble constituents of tea contained in its infusion consist of gum, grape sugar, a large proportion of tannin, a volatile oil, and a peculiar nitrogenized principle called theine, which is the same as that found in coffee and in the Paraguay tea or maté, or holly, of which an account has been given in the article *CAFFEINE*. The theine forms but a very small proportion of its substance, the largest quantity that has been separated not exceeding 6 per cent. Stenhouse rated its proportion in the teas of commerce at about 2 per cent. In the analyses of G. J. Mulder its proportion is doubtless underrated; these are as follows:

Constituents.	Chinese.		Japanese.

The aroma and flavor and some of the effects of tea upon the nervous system are mainly due to the volatile oil. This is developed in the roasting and drying, and its effects are most strongly exhibited in new teas. Those persons whose business it is to inspect teas, which they do by tasting, and are known as tea tasters, are subject to frequent attacks of headache and giddiness, and paralysis is a common complaint with those employed in packing and unpacking chests of tea. Theine is regarded as lessening the waste of tissue, and consequently taking the place of other food. Tannin imparts to the tea its astringent taste and property, and causes it to exert a slightly constipating effect upon the bowels. When fully

extracted by long continued steeping, it is then very perceptible by the bitter taste which it imparts to the tea. The glutinous matters are lost with the leaves unless these are consumed with the infusion after the practice of the Japanese, who reduce the leaves to powder. An addition of soda would cause more gluten to appear in the infusion.—The virtues of tea have been highly extolled from the time of its earliest use as a beverage. Lo Yu, a learned Chinese who lived in the dynasty of Tang, A. D. 618 to 906, says of it: "It tempers the spirits and harmonizes the mind; dispels lassitude and relieves fatigue; awakens thought and prevents drowsiness; lightens or refreshes the body, and clears the perceptive faculties." These effects are true of tea taken in moderate quantity, and its soothing influence is such that it is frequently beneficial in inflammatory diseases, and a strong infusion of tea relieves nervous headache. But when taken in excess it acts as a narcotic upon some constitutions, producing nervous tremblings; and in inferior animals it has been known to produce paralysis. Green tea is much more objectionable in this respect than black.—The principal black teas imported into the United States during the last 10 years, in the order of their relative quantities, are oolong and ningyong, souchong and congou, pouchong, orange pekoe, and pekoe. The green are young hyson, gunpowder, imperial, hyson, twankey, and hyson skin. The average net weight of a chest of tea is about 64 lbs., which is the weight of congou tea; pekoe and hyson weigh usually 49 lbs., and bohea 188 lbs. The twankey, which is of the lowest quality, is largely used for mixing with better teas, and is said to constitute $\frac{1}{4}$ of all the green teas imported into Great Britain. Hyson skin is the refuse of the finer hyson, and is largely purchased by American merchants. Gunpowder is so named from the granular appearance of the leaves, which are rolled with particular care; the Chinese name for it means pearl tea. Young hyson is so named from the early season in which its leaves are gathered; as very inferior teas have been passed off for this, its reputation is

now lost.—The exportation of tea from China is from 8 ports only, Shanghai, Foochow, and Canton; and the principal portion of the exports to the United States is from the first named, the most northern of the 8 places. The countries which take nearly the whole of this product are Great Britain, the United States, Russia, and Holland. In 1853 the exportations were as follows: Great Britain, 65,187,200 lbs.; the United States, 84,834,000; Australia, 8,829,000; Holland, 8,000,000; India, 800,000; other places, 2,200,000. It is supposed that from 14,000,000 to 15,000,000 lbs. are annually sent overland to Russia. The trade with the United States first attained any importance in 1790, and up to the close of the year 1800 the imports averaged 2,500,000 lbs. per annum; for the next 12 years 8,850,000 lbs.; and to the end of 1820 there was but little variation from this. From that time to the end of 1833 the consumption, ascertained by deducting the exports from the imports, averaged about 7,000,000 lbs.; from that time to the close of 1841 the average annual consumption was 12,752,168 lbs. The consumption has been chiefly in the N. E. portion of the United States, tea being used exclusively in some of the most northern portions, the use of coffee gradually increasing toward the south, till in some parts of the southern states tea is entirely unknown. At the west also tea is less used than coffee. The following table presents the exports from China to the United States for the years named, as prepared by United States merchants in China, reckoning to July 1 of each year:

Years.	Green tea, lbs.	Black tea, lbs.	Total, lbs.
1854-'55.....	21,669,509	8,572,900	30,242,400
1855-'56.....	24,314,500	15,219,200	39,533,700
1856-'57.....	17,408,300	7,868,900	25,277,200
1857-'58.....	17,523,400	11,736,900	29,260,300
1858-'59.....	18,000,800	12,172,500	30,173,300
1859-'60.....	18,284,900	18,423,200	36,708,100
1860-'61.....	2,251,200	12,328,100	14,579,300

The imports, deliveries, and exports of tea in and from the United Kingdom were as follows for the years named:

Years.	Imports.	
	Green, lbs.	Black, lbs.
1849.....	9,166,000	43,234,000
1850.....	8,437,000	40,873,000
1851.....	9,268,000	39,314,000
1852.....	9,814,000	55,386,000
1853.....	11,349,000	58,451,000
1854.....	8,601,000	70,089,000
1855.....	13,080,000	70,970,000
1856.....	10,594,000	77,147,000
1857.....	12,713,000	51,780,000
1858.....	8,334,000	63,066,000
1859.....	8,043,000	62,457,000

Ball (8vo., London, 1848); "Three Years' Wanderings in the Northern Provinces of China," by Robert Fortune, botanical collector to the horticultural society of

London (1847); "Two Visits to the Tea Countries of China and the British Tea Plantations in the Himalaya," by the same (1853); "The Middle Kingdom," by Dr. S. Wells Williams (3 vols. 8vo., 4th ed., 1857); "Report on the Government Tea Plantations in Kumaon and Gurwhal," by William Jameson, superintendent of

botanical gardens, N. W. Provinces, India, in the "Journal of the Agricultural and Horticultural Society of India" (vol. vi., Calcutta, 1848).

TEA, PARAGUAY. See HOLLY.

TEACHERS' INSTITUTE, in the United States, an assemblage of the teachers of the public schools of a county or part of a county, for a period of from 2 to 4 weeks, usually in the spring or autumn, for the purpose of receiving instruction in the art and methods of teaching, by lectures, conferences, and class drills, from experienced practical teachers. The instruction is free, and the families of the town or village where the institute is held usually receive those who attend as guests during its session. The first teachers' institute was organized by the Boston academy of music, in Aug. 1834, for "instruction in the methods of teaching music." The first application of it to the instruction of teachers of public schools was made by Mr. Henry Barnard at Hartford, Conn., where in the autumn of 1839 a class of 26 young men, and in the spring of 1840 a class of 16 young women, were taught. Institutes have assembled in New York since 1842 or 1843, and an appropriation was made for their support from the state treasury in 1847; in Massachusetts, Rhode Island, and Ohio since 1845; in Pennsylvania since 1851; and they were commenced about the same time in Indiana, New Hampshire, and New Jersey, and the other northern states, where legislative provision is generally made for defraying their expenses. The instruction in these temporary training schools is necessarily almost wholly oral; and as there is neither time nor occasion for lessons in the studies to be taught in the public schools, it is confined to an explanation and illustration of the best methods of teaching and governing schools. Those who conduct the institutes have usually had large experience in teaching, being often the principals or professors in the normal schools. The lectures are practical, and usually on some particular educational topic, such as physiology, grammar, physical geography, modes of discipline, &c. Conferences are held, in which the teachers relate their own experience of particular methods of instruction and discipline.

TEAK WOOD, a variety of timber much used in ship building and house carpentry in the East. It is the product of the *tectona grandis* and other species of large forest trees of the mountainous districts of the Malabar coast, of Burmah, and of various islands in the Indian seas. The tree of the common species grows to an immense size, the leaves from 12 to 24 inches long and from 8 to 16 inches broad, and furnishes single sticks of timber sometimes 50 feet long and 2 feet square. Of all the timber obtained in the East, this is esteemed most valuable. The wood is of light brown color, and works easily, although, containing much silicious matter, it is somewhat destructive to tools. Its weight to the cubic foot, when moderately seasoned, is from 45 to

52 lbs., as obtained from Malabar; but some inferior sorts from other places weigh only about 42 lbs. While the timber possesses the strength of oak, it is much more durable. It seasons quickly, shrinking very little, and is not liable to dry or wet rot, even if used directly from the forest. It contains a resinous oil, which protects it alike from decay and from the attacks of insects. The Burmans extract this oil by tapping the trees, and use it chiefly for protecting their pagodas from the weather; but the timber thus exhausted of its oil is injured as respects its durability. Teak is largely exported to Calcutta and Madras from Malabar, obtained from the extensive forests in its vicinity, and much is consumed in ship building in that locality. The teak of Malabar, which is esteemed the best, is extensively used in the ship yards at Bombay. At the great exhibition of 1851 in London, the naval department of the East India company contributed specimens of more than 70 species of teak.—The timber known as African teak, brought from the W. coast of Africa, belongs to an entirely different genus of trees, and is greatly inferior to the East Indian teak. It has been supposed to be a *vitez*, and by some to belong to the *euphorbiaceae*.

TEAL, the common name of the small river ducks of the genera *nettion* (Kaup) and *querquedula* (Stephens), called *sarcelles* by the French. In the genus *nettion* the bill is as long as the head, straight, unusually narrow, with sides parallel, high as broad at the base, the depressed tip with a very narrow nail; wings moderate and pointed, 2d quill the longest, and the secondaries lengthened and pointed; tail moderate and wedge-shaped; toes united by a full web, the hind one short and slightly lobed. There are about 20 species, distributed all over the globe, though most numerous in the northern hemisphere; they are migratory, commencing their rapid flights in small flocks soon after sunset, resting by day on the surface of fresh water or the reedy shores of rivers and lakes, and feeding principally at night on aquatic insects and worm-seeds, and grains; the nest is made of a large mass of decayed vegetable matter lined with down, and the eggs are 8 to 10; they are highly esteemed as game. The European teal was domesticated by the Romans, and might be by the moderns with proper attention to its food and habits, making a very handsome and profitable addition to the poultry yard. The green-winged teal (*N. Carolinensis*, Baird) is 14 inches long, 22 to 24 in alar extent, and the bill 1½; the head and neck are chestnut, the chin black, and the forehead dusky; around the eyes and on the sides of the head is a broad rich green stripe, passing into a bluish black patch on the nape; below white, with rounded black spots on throat; lower neck, sides, and scapulars finely banded with black and grayish white; speculum on wings broad and rich green; a white crescent in front of bend of wings; under

tail coverts black, with a patch of buff white on each side; wing coverts plain olive gray; in the female the under parts are white, and the upper dark brown with gray edgings. It occurs over the whole of North America, and accidentally in Europe; it migrates principally over the land, breeding from the great lakes to the fur countries; it runs well, is a good swimmer and diver, and a very rapid and graceful flier; having a comparatively long neck, it feeds while swimming, and, being choice in its selection of food, affords a delicious flesh, much superior, according to Audubon, to that of the canvas-back; it is not very shy; the eggs are $1\frac{1}{4}$ by $1\frac{1}{4}$ inches, much rounded, dull yellowish with indistinct deeper tints. The English teal (*N. crecca*, Kaup) differs from the above in having no white crescent in front of the bend of the wings; the elongated scapulars are velvet black externally and creamy white internally; this has occasionally been observed on the E. coast of the United States.—In the genus *querquedula* the bill widens a little to the end, which is obtusely rounded, is higher than broad at base, has a wider nail and the lamellae visible on the sides. There are about half a dozen species in North America, Europe, and Asia, with habits similar to those of the other genus. The blue-winged teal (*Q. discors*, Steph.) is 16 inches long, 24 or 25 in alar extent, with a bill of $1\frac{1}{2}$; the head and neck above are plumbeous gray; top of head black; white crescent in front of eyes; under parts purplish gray, each feather spotted with black; fore part of back brownish with 2 narrow bands of purplish gray; back behind and tail greenish brown; under tail coverts black; outer webs of some of the scapulars and the wing coverts bright blue; greater coverts tipped with white, with grass-green speculum below them; bill black; in the female the top of the head is brown, chin and throat yellowish white, back brown with paler edgings, under parts whitish with obscure brown spots, and the same blue and white in the wings as in the male. It is found throughout eastern North America to the Rocky mountains, but not in Europe; it is very abundant about the mouths of the Mississippi in winter, and is less hardy than the green-winged species; the flocks pass and re-pass many times over a place before alighting, and the glistening of their wings in the sun is like that of polished steel; it is easily kept in captivity, thriving on coarse corn meal, and could be domesticated with a little care. This species is replaced west of the Rocky mountains and on the Pacific coast by the red-breasted teal (*Q. cyanoptera*, Baird), a larger bird, of a general purplish chestnut color, without white on the head or tail; the feathers of the flanks are uniform chestnut.

TEARS, the limpid, colorless, slightly saline secretion of the lachrymal glands, continually poured out in quantity sufficient to bathe the surface of the eyes, to secure the easy and free motion of the lids, and to wash off any irritat-

ing particles from their sensitive membrane. The lachrymal belong to the aggregated glands, or those in which the vesicles or *acini* are arranged in lobules; there is one situated at the upper, external, and anterior part of each orbit, in a depression of the frontal bone, in relation with the external rectus muscle, resting behind on a fatty areolar tissue; each gland is of the size of a small almond, of reddish white color and flattened form, enveloped in a fibro-cellular capsule, and receiving an artery, vein, and nerve of the same name; the secretion is poured out by 6 or 7 trunks opening within the upper lid. At the inner angle of the eyes, in both lids, are 2 very narrow, always open apertures, the lachrymal *puncta*, situated in the middle of a slightly prominent tubercle, about $1\frac{1}{4}$ lines from the inner junction of the lids; they are opposite each other, the lower turned up and the upper down, and both outward and backward. Through these openings the tears are conveyed by the short lachrymal ducts in each lid to the lachrymal sac, situated at the inner angle of each eye, in the bony groove between the lachrymal bone and the ascending process of the superior maxillary; it is a small membranous sac, opening below into the nasal duct, which conveys the tears into the nose beneath the inferior turbinated bone, explaining why after a copious secretion of tears it becomes necessary to blow the nose. At the inner angle of the lids, in front of the globe and behind the lachrymal points, is a small reddish tubercle, pyramidal with the summit turned forward and outward; this is the lachrymal caruncle, and consists of a mass of small mucous follicles, covered by the conjunctiva, which forms in front and to the outside a semilunar fold, called the nictitating membrane; this is rudimentary in man, but remarkably developed in birds. The act of crying, generally accompanying an increased secretion of tears, as far as the movements of respiration are concerned, is very nearly the same as that of laughing, though occasioned by a contrary emotion; the expiratory muscles are in more or less violent convulsive movement, sending out the breath in a series of jerks, accompanied by well known sounds; in children the act is sometimes continued almost to the complete emptying of the chest of air, to the great dismay of parents, but the *besoin de respirer* is always stronger than the convulsive muscular movements. Moderate excitement, whether of joy, tenderness, or grief, increases greatly the quantity of the tears, though the secretion is checked by violent emotions; in intense grief the tears do not flow, the restoration of the secretion being a sign of moderated sorrow, and itself affording relief by the resumption of nervous action previously held in abeyance by great mental depression. Considering their size, there are no other glands which ordinarily can so increase the amount of their secretion as the lachrymal; the quantity is sometimes very great, and very easily stimulated; the shedding of tears is also

decidedly contagious, and it is for most persons difficult to see any one weeping without feeling their own eyes fill with tears.—The lachrymal gland is rarely diseased, though it is subject to inflammation, and to morbid growths, for which it has been extirpated. *Xerophthalmia* is a disease in which the eyes are dry from deficiency of the tears or of the mucous secretion; the best remedy is bathing the organs by means of the eye cup with tepid water. In *epiphora* the tears are secreted so abundantly that they run over the cheeks, the lachrymal ducts not being able to convey them off fast enough; it is not uncommon in scrofulous persons with very irritable eyes, and is best treated by alteratives and tonics, with soothing and gently astringent applications; this symptom is sometimes caused by foreign bodies or inverted lashes. The lachrymal puncta may be closed, causing the tears to flow over the cheeks, for which the remedy is dilatation by fine probes. When the nasal duct is obstructed, the eye is watery and the corresponding nostril dry, the sac forming a small tumor at the side of the nose; the sac also may be inflamed, with pain, tenderness, swelling, and feverish symptoms; this may end in suppuration and an external opening, constituting lachrymal fistula, requiring the restoration of the obliterated duct by styles of different materials, as described in surgical works.

TEASEL (*dipsacus fullonum*), a European plant, greatly improved by cultivation, used for dressing cloths. It has a fleshy root which branches and tapers; an erect, furrowed, prickly stem, branching near the top, 5 or 6 feet high; sessile, entire leaves, spiny on the margins and surfaces, those of the stem opposite and joined at base, and generally filled with water, whence its generic name *dipsacus* (Gr. *διψακος*, thirsty). The disposition of the flowers reminds one of the composite order, being numerous and collected upon a cylindrical head; but from certain structural peculiarities the teasels and the scabiouses form a distinct natural order termed *dipsacaceae*. The corolla is monopetalous, tubular, 5-lobed, of a whitish color, the stamens having pale purple anthers. Rigid, spiny scales, recurved at the apex, surround each floret; and when the flowers have faded, the dried and ripened receptacles are gathered and selected with great care, being assorted according as they are terminal, lateral, or secondary growth, the first being the best for use. The head forms a sort of brush which is found to be better adapted for raising the nap on woollen fabrics than any artificial substitute that has been contrived. The teasels are attached when in use to the periphery of a large, broad wheel, which is made to revolve so as to bring them in contact with the surface of the cloth. The profits from teasel culture are very uncertain, much depending upon the weather and on the condition of the soil.—The wild teasel (*D. sylvestris*, Miller), supposed to be the original of the cultivated kind, is a common plant by road-

sides and near hedges, and is sometimes found in similar spots in the United States, being however adventitious.

TECUMSEH, a North American Indian, chief of a tribe of the Shawnees, born on the banks of the Scioto river, near Chillicothe, O., about 1770, killed in the battle of the Thames, O. W., Oct. 5, 1818. He was one of 8 brothers brought forth at the same birth. The others were Kumshaka, who probably died young, and Elakwatawa, better known as the prophet. An engagement with Kentucky troops which took place on Mad river, when he was perhaps not more than 20, is the first fight with white men at which Tecumseh is known to have been present, and it was reported by some of his tribe that he then ran at the first fire; yet in the war that ended with the treaty of Greenville in 1795, he became celebrated as one of the boldest and most active of the Indian warriors. About 1804 he formed, in conjunction with his brother the prophet, a project to unite all the western Indians in a defensive alliance against the whites. Tecumseh visited all the tribes on the W. bank of the Mississippi, and upon Lakes Superior, Huron, and Michigan, and the prophet pretended to be commissioned to the Indians from the Great Spirit and began to preach against the influence of the white men. Both had considerable success, and in 1811 the prophet had finally gathered around him at Tippecanoe on the Wabash a force of several hundred warriors. Governor Harrison's investigations in relation to this force brought on the battle of Tippecanoe, Nov. 7, 1811, in which the Indians were defeated. Tecumseh's plan was not yet mature, and this battle ruined it. His next endeavor was in the alliance with the English. He received the rank of brigadier-general, commanded all the Indians who co-operated with the English in the campaigns of 1812-'13, was present at every important action previous to that on the Thames, and took a conspicuous part in the skirmishes that preceded Hull's surrender of Detroit. In the battle on the Thames, near the Moravian town, he commanded the Indian and English right wing, and was posted in the only part of it that was engaged with the U. S. troops. The Indians were driven back, but Tecumseh rushed forward where the American fire was thickest and fell. He was generally said to have been shot by Col. R. M. Johnson, afterward vice-president of the United States; but there was never any foundation for the statement, and it is now no longer credited.

TEETH, the organs in vertebrates for the seizure and mastication of food, placed at or near the entrance to the alimentary canal. In adult man there are 32, 16 in each jaw, implanted in sockets, and of an irregular conoid form; in the child there are only 20. For their development see DENTITION. Their number increases in the lower animals, being greatest in the cetaceans and marsupials among mammals, and also considerable in many rep-

tiles and fishes. The portion of a tooth above the socket is called the crown, the concealed part the root or fang, between these being a more or less well marked constriction or neck. Vertebrate teeth, like bones, have for their earthy basis phosphate of lime, the enamel also containing fluato of lime; the teeth of invertebrates consist essentially of carbonate of lime. The body of a tooth is composed of a tissue called dentine, the outer crust of the cement or *crusta petrosa*, with generally a thin covering of enamel on the grinding surface. Dentine is disposed in the form of very minute cells and tubes of an animal gelatinous basis, containing the earthy matter, some of its varieties closely resembling bone; the cement corresponds in texture with the osseous tissue of the animal, forming nearly $\frac{1}{3}$ of the mass of the elephant's molars, and wearing away sooner than the dentine; the enamel is the hardest constituent of the tooth, and the hardest of the animal tissues, consisting of the earthy matter contained in the canals of an animal matrix.—There are 8 kinds of teeth distinguishable in mammals, viz., incisors, canines, and molars. The incisors are situated in the front and median portion of the jaws, and have a simple flattened root and a thin cutting edge, suitable for dividing and collecting food, as in the jaws of the beaver and squirrel and in the lower jaw of the ox. The canines, 4 in number, are next to the incisors, separated from them by an interval, except in man; the crown is conical, and the root long and simple; they are the so called eye and stomach teeth in man, and form a striking character and very formidable weapons in the carnivora; they are best adapted for securing and tearing a living prey. The molar teeth are the most posterior, and have flattened and tuberculous crowns suited for grinding down vegetable food; they are most developed in herbivorous animals; the roots in man are often much bifurcated, rendering extraction difficult.—Teeth are so intimately related to the food and habits of animals, so easily examined from their situation, and of such indestructible materials, that they are of the first importance in the classification of animals, both living and fossil. The importance of the teeth in preparing food for the digestive process has been noticed under DEXTERION; in man they are also subservient to beauty and to speech; when fully formed they are subject to decay, but have no inherent power of reparation; they may increase by abnormal growth of the cement, their most highly organized constituent. For the diseases and the mode of treatment of the teeth, see DENTISTRY.—In fishes the teeth vary from none in the sturgeon and lophobranchs to countless numbers in the pike and the silurids; they are usually conical, but sometimes flattened or pavement-like, villiform, serrated, and cutting; they may be situated on any of the bones of the oral cavity, on the tongue, and in the pharynx; in most cases they are firmly united to the jaws by continu-

ous ossification, but in some are movable; they are composed of dentine and its modifications, enamel occurring in only a few cases, like the parrot fish (*scarus*); and they are frequently shed and renewed, the germs being developed from the free surface of the buccal membrane. Among reptiles, the whole order of chelonians (tortoises and turtles), and also the toad family among batrachians, are without teeth; in the others these organs are usually simple, and adapted for seizing and holding but not chewing their food; the number is never so small nor so large^{as} in fishes, and is rarely characteristic of species; they are generally conical, sharp, and smooth, and may be placed on any of the bones entering into the structure of the mouth; the base never branches into diverging fangs, and in most is ankylosed in various ways to the bone which bears them, as noticed under the different families; dentine and cement are always present, and sometimes enamel, as in the saurian crown. Among mammals, some of the edentates, as ant-eaters and pangolins, have no teeth; in the others they are implanted in sockets, and the molars have 2 or more roots when they have a limited growth; they are confined to the superior, inferior, and intermaxillary bones, a single row in each. Mammals have been divided by Owen into monophodonts, or those which generate a single set of teeth, and diphyodonts, or those which generate 2 sets of teeth; the former include the monotremes, edentates, and carnivorous cetaceans, and the latter all the other orders. The teeth of mammals and their dental formulas have been sufficiently described in their respective divisions.—For full details on this subject the reader is referred to the following writings of Prof. Richard Owen: "Odontography" (London, 1840-'45); article "Teeth" in vol. iv. of the "Cyclopædia of Anatomy and Physiology" (1852); and "The Principal Forms of the Skeleton and Teeth," in vol. i. of Orr's "Circle of Sciences" (London; reprinted in Philadelphia, 1854).

TEETH, MINERAL. See DENTISTRY, vol. vi. p. 396.

TEFFT, BENJAMIN FRANKLIN, D.D., LL.D., an American clergyman, born in Oneida co., N. Y., in 1818. He commenced a course of classics and mathematics at an early age, and at 15 entered upon the study of law, but subsequently, after receiving a collegiate education with a view to the ministry, applied himself for 4 years to legal, metaphysical, and historical studies. He then became pastor of a Methodist Episcopal church at Bangor, Me., and two years later president of a classical seminary at Providence, R. I., where he remained one year; and after residing for a year in Boston, he was called to the professorship of Greek and Hebrew in the Indiana Asbury university, where he remained 3 years. He has since been general editor of the books and magazine of the Methodist book concern at Cincinnati, and still later president of Gene-

see collage. He has published "The Shoulder Knot, or Sketches of the Threefold Life of Man" (New York, 1850); "Hungary and Kossuth, or an American Exposition of the late Hungarian Revolution" (Boston, 1852); and "Methodism Successful, and the Internal Causes of its Success" (New York, 1859).

TEFLIS. See TIFLIS.

TEGEA, an ancient and powerful city of Greece, situated in the S. E. part of Arcadia. Its territory was called Tegeatis. It is mentioned in the Iliad. Its early history was marked by a constant war between it and the Spartans, who for a long time unsuccessfully attempted to bring about its subjection. Charilaus, a Spartan king, invaded at one time the land of the Tegeans, but was defeated and made prisoner. Two centuries later Leon and Agesicles were unsuccessful in another invasion; but about 560 B. C. the city fell into the hands of the Spartans, and though retaining its independence was bound to furnish a military force when required. In the Persian war 500 Tegeans fought at Thermopylae, and at Platæa 8,000. Subsequently they were again at war with Sparta, and were defeated; but during the entire Peloponnesian war they adhered constantly to the side of the Spartans, as they did also in the Corinthian war which followed. After the battle of Leuctra in 371, the Spartan party having been expelled, Tegea became a member of the Arcadian confederacy, and its citizens in 362 fought under Epaminondas at Mantinea. Subsequently it joined the Ætolian league, and in the wars between Sparta and the Achæan league was alternately in the hands of the contending parties. After the Roman conquest of Greece, it continued to be a place of considerable importance, but toward the close of the 4th century of the Christian era was taken and totally destroyed by Alaric.

TEGNÉR, ESAIAS, a Swedish poet, born at Kirkerud, Wermland, Nov. 13, 1782, died in Wexiö, Nov. 2, 1846. He was graduated at the university of Lund in 1803, and made professor of Greek literature there in 1812, having in the interval been an under professor. A patriotic poem entitled *Svea* (Sweden) was his first production, and obtained for the author the prize of the Swedish academy. In 1824 he was made bishop of Wexiö, and from that period devoted himself to his episcopal duties. The most admirable of Tegnér's poems is *Frithiofs Saga* ("The Legend of Frithiof"), which first appeared in 1825. It consists of 24 cantos, of different metres, each according to the style of the subject, and in imitation of the old Icelandic sagas. The most striking passages have been admirably set to music by Crusell, a Swede, and are constantly sung in family circles throughout the country. Among the works of Tegnér may be cited also the "First Communion," "Axel," the story of a lifeguardman of Charles XII.; the "Song of the Sun," a fine bacchanalian; the "Hero," a sketch of Napoleon; the "Sage," a didactic poem; and

Nattwardsbarnen ("The Children of the Lord's Supper"). His writings were collected and edited by his son-in-law Prof. Bottiger (6 vols. Stockholm, 1848). The best translations of Tegnér's poems, according to his own opinion, are those of Longfellow.

TEHAMA, a N. co. of California, drained by the Sacramento river; area, about 1,000 sq. m.; pop. in 1860, 4,044. The surface is hilly, and the soil fertile and well adapted to grazing. The productions in 1858 were 188,450 bushels of wheat, 232,000 of barley, and 18,886 lbs. of wool. A large amount of timber is exported. There are two Indian reservations in the county, on which 8,000 Indians are settled. Capital, Red Bluffs.

TEHERAN, or TEHRAN, the capital of the kingdom of Persia, and of the province of Irak-Ajemi, 70 m. S. from the Caspian sea and 210 m. N. from Ispahan, in lat. 35° 41' N., long. 51° 28' E.; pop. in winter about 80,000. The town stands in a sandy plain, with mountains to the N. and E., and a fertile, well cultivated country to the W. It is of a square form, surrounded by thick walls about 4 m. in extent, and is entered by 4 gates ornamented with the figures of different kinds of animals. Inside there are many vacant spaces and gardens and extensive ruins; but the streets are narrow, irregular, unpaved, and exceedingly filthy. The houses are badly built and mean in appearance. The royal palace consists of a great number of buildings and gardens, and covers nearly $\frac{1}{4}$ of the area enclosed within the walls. It is fortified, and has a seraglio surrounded by lofty walls and guarded with great care. The bazaars are extensive, but are wretchedly kept and very dirty. There is a royal foundry, where guns of large caliber are made. One of the mosques is roofed with plates of gold. In summer the climate is unhealthy, and the monarch and about $\frac{1}{10}$ of the inhabitants leave the city and encamp on the plains of Sultanieh. On a hill in the neighborhood the king has a palace and beautiful gardens.—Under the Saffavian dynasty Teheran was not a place of importance. It was almost destroyed by the Afghans after the battle of Salman-abad; but it was afterward rebuilt, and has since received frequent additions to its fortifications. It was made the capital of Persia in the early part of the 18th century.

TEHUANTEPEC, a territory of Mexico, organized about 1850, and comprising the isthmus of the same name, bounded N. by the gulf of Campeachy, E. by the states of Tabasco and Chiapas, S. by the gulf of Tehuantepec, and W. by Vera Cruz and Oajaca; area, about 16,000 sq. m.; pop. in 1854, 82,895. Its width from gulf to gulf is 180 m. It is drained by the Coatzacoalcos river, which flows northward, discharging into the gulf of Campeachy, and extending about $\frac{1}{4}$ of the width of the territory; and by the Tehuantepec river, flowing into the gulf of the same name. There are several lakes and lagoons in the territory.

Capital, Minatitlan.—At one time it was proposed to construct a ship canal across the isthmus, improving the navigation of the Coatzacoalcos for a part of the distance, and using some small lakes as reservoirs at the height of land for the canal; but a subsequent project was the connection of the gulf and ocean by a railway which should form a part of the route from New Orleans to San Francisco, the isthmus being S. S. W. of New Orleans, and the route shorter by several hundred miles than any other proposed ocean route. Measures were taken to secure the grant of the route from the Mexican government, and it was provisionally opened by the despatch of vessels to the ports on either side, and the transportation of passengers by stage across the isthmus. The want of any good harbor on either side of the isthmus, and the immense expense which would be incurred in the erection of breakwaters adapted to produce even a partial shelter, as well as the shallowness of the harbors, have caused the project to be relinquished.—TEHUANTEPEC, a town of the above territory, is situated on Tehuantepec river, about 10 m. above its mouth, and 150 m. E. S. E. from Oajaca; pop. 14,000. It has salt works and cotton factories, and a considerable pearl fishery in which many of the inhabitants are engaged. Indigo is raised in the vicinity, and a purple dye is procured from a shell fish abundant there. The harbor is shallow and exposed to the hurricanes from the N. W.

TEIGNMOUTH, JOHN SHORE, an English statesman, born in Devonshire, Oct. 8, 1751, died Feb. 14, 1834. He entered the civil service of the East India company as a cadet in 1769, and by successive promotions reached in 1793 the position of member of the supreme council under the governor-general, Lord Cornwallis, whom in 1798 he succeeded in office, and in 1794 he was made a baronet. The new settlement of landed property in the presidency of Bengal, and the new judicial system introduced under Lord Cornwallis, were mainly attributable to the efforts of Sir John Shore. He retired from office in the latter part of 1797, and was created Baron Teignmouth in the peerage of Ireland. Subsequently he was for many years a member of the board of control, and from 1804 until his death president of the British and foreign Bible society. He published in 1804 a memoir of Sir William Jones, whom he succeeded as president of the Asiatic society, and in 1807 he edited his works in 18 vols. 8vo. His "Life and Correspondence" was published by his son (2 vols., London, 1837).

TELEDU, or TELAGON, the name of the *mydas meliceps* (F. Ouv.), a carnivorous animal of the family *mustelina*, emitting a fetid odor like that of the skunk, inhabiting Java, and confined exclusively to mountains 7,000 feet at least above the level of the sea. It is about the size of a polecat, being 15 inches long with a tail of half an inch, but the body is much thicker, the neck and limbs short and stout, and the

feet plantigrade; the teeth are as in the skunk, the snout prolonged like that of a pig, the head badger-like, ears very small and concealed by the long hair, and the eyes very high in the head; the claws of the fore feet are long, compressed, nearly straight, and adapted for digging; the fetid secretion is poured out from 2 glands near the end of the rectum, opening about half an inch within the canal. It is a nocturnal animal, making a shallow burrow, and feeding on insects, larvæ, and worms. The color is blackish brown, with a narrow whitish stripe extending from the occiput to the tail. It is slow in its movements, trusting for safety to its fetid odor; the natives are fond of its flesh, which is almost always fat and tender; it sometimes does considerable mischief by destroying the roots of young plants in cultivated districts.

TELEGRAPH (Gr. *τῆλε*, afar, and *γραφω*, to write), an apparatus by which intelligence is communicated to a distance. It properly includes the various methods of signalling, of which some account has been given in the article SIGNALS. The most obvious form of these, and one which has been adopted by different nations from remote antiquity, is that of fires made upon commanding points, which were visible at great distances, by their smoke by day and their light by night. By preconcerted arrangements, these are made to designate such intelligence as it may be desirable to communicate, such as the warning of the approach of an enemy, and to call the people together for their protection. The Roman generals, as described by Julius Africanus, perfected this method of communicating intelligence, so as to spell words by means of fires of different substances. The North American aborigines made use of regular stations over the western country for these signals; and the Indians of the north-west territory in this way communicated intelligence of the approach of Fremont, as he passed through their regions. Polybius describes two methods of telegraphing by means of torches; and Bishop Wilkins, after giving an account of this in his book entitled "Mercury, or the Secret and Swift Messenger," describes a method of conversing at a distance with 8 lights or torches at night, which may be so used as to indicate the 24 necessary letters of the alphabet, these being divided into 8 classes of 8 letters each, which are severally designated by one, two, or three torches, and the number of the letter by the number of times the torches are elevated or displayed. Another method was also proposed by Bishop Wilkins, in which intelligible signals were conveyed by means of two lights attached to long poles; and for long distances he suggested the use of the then newly invented telescope, or, as he called it, "Gallileus his perspective." A variety of systems of telegraphic signals were brought into notice by different inventors in the 17th and 18th centuries, one of the earliest of which was that of Dr. Robert Hooke described in the "Philosophical Trans-

actions" for 1684. It consisted of 24 symbols formed of blocks of wood, representing alphabetic characters, and 6 more formed of curved lines to be used as arbitrary signals. These were to be exposed in succession in an elevated frame at some conspicuous point, and being observed at another station were to be there repeated and sent forward to the next, and so on. At night torches or other lights were to be substituted for the wooden figures. The first working telegraph of much importance was that known as Chappe's, which was brought into use during the wars of the French revolution. At the top of a tall post was attached a cross bar upon a pivot, so that it could be easily turned from a horizontal to an inclined position. Each end of this cross bar carried a short arm, which could also be turned upon its pivot so as to stand in any position in relation to the bar. The movements were made by means of ropes which passed through the bar and down the post. This apparatus admitted of 256 distinct signals; but M. Chappe limited its use in great part to 16 signals, each one of which represented a letter of the abbreviated alphabet he had constructed. The news of the recapture of Lille was conveyed in 1794 by this telegraph to Paris in an hour after the troops of the republic had entered the place. Mr. R. Lovell Edgeworth at about the same time brought before the public his plan of a telegraph, or as he called it telegraph or tellograph, by which the signals represented numbers, the meaning of which would be found in the dictionary prepared for this system. The signals were made by means of 4 pieces of wood, each one in the form of a long isosceles triangle, placed near together, each supported upon a pivot round which it could be turned in any direction. The movements of each were limited to 8 in number, and indicated the first 7 numerals and zero. The first triangle or pointer represented units, the 2d tens, the 3d hundreds, and the 4th thousands, so that any number might be expressed that did not contain the figure 8 or 9. The admiralty telegraph proposed by Lord G. Murray was used in England from 1795 to 1816, when it gave place to that known as the semaphore (Gr. *σημα*, a sign, and *φέρειν*, to carry), which the French had adopted in 1808. This consisted of 6 conspicuous boards or shutters set in a frame, each of which could be turned upon its axis so as to present either its edge or broad surface to the next station. The movements represented figures, and a series of numbers was indicated by their combinations. Some of these stood for the letters of the alphabet, and the others for arbitrary signals. The French semaphore (also known as signal posts) consisted of 8 or more arms attached by pivots to an upright post, admitting of motion in any direction, and indicating by their various positions either figures or letters. Many modifications of the apparatus were introduced into the English navy, as well as upon the land, by Sir Home Popham and Capt. O. W. Pasley,

the most used of which, until the introduction of the electric telegraph, was that adopted by the admiralty in 1816. It was formed with two arms only, one at the top of a hollow hexagonal mast, and the other at some distance lower down. Each of these arms admitted of 6 different positions, easily distinguished from each other, and the two together could afford 48 signals, which are sufficient to express the letters of the alphabet and the Arabic numerals, and leave 18 for other signs. The mast was made to turn upon its foot, so as to display the signals in any direction. For holding telegraphic communication at sea, flags of various colors have long been used. (See SIGNALS.) It has been proposed to employ a small helioscope or mirror for reflecting a ray of light from the sun as a means of communicating signals in clear weather. With a mirror so small that it may be carried in the waistcoat pocket, flashes of light may clearly be perceived for 12 miles or more, and the mirror being gently moved on some established system the appearance and disappearance of the flashes may indicate letters or words. Mr. Francis Galton, the African traveller, who proposed this at a meeting of the royal geographical society, described an optical arrangement he had devised by which the operator may know if the mirror is directed aright. Among the later publications upon the telegraphs adopted previous to the electric telegraph, are papers in the "Journal of the Society of Arts," vols. xxvi., xxxiv., xxxv., and xxxvi.; "A Treatise explanatory of a new System of Naval, Military, and Political Telegraphic Communications," &c., by John Macdonald (London, 1817); "Description of the Universal Telegraph for Day and Night Signals," by O. W. Pasley (London, 1823); and Edgeworth's "Essay on the Art of conveying Secret and Swift Intelligence," in the "Transactions of the Royal Irish Academy," vol. vi. —ELECTRIC TELEGRAPH. It would seem that the idea of employing electricity for telegraphing should soon have followed the discovery, made about the year 1729, that the shock could be transmitted long distances through conducting media with great rapidity. But the attention of the early experimenters was chiefly directed to some of the more obvious phenomena developed by the newly invented Leyden jar, such as communicating the electric shock to a large number of persons in a continuous chain; the firing of alcohol by an electric charge sent through wires under water, as performed by Franklin across the Schuylkill river in 1748; the establishment of the identity of lightning and electricity, also determined by him at about the same time, &c. The electricity then known, which was produced only by friction, disappearing with each discharge, was not at all adapted for communicating signals, which requires a continuous current. The various discoveries which gradually led to the perfection of this system, together with occasional experiments relating to it, may be noticed in their chrono-

logical order. The discovery by Dr. Watson in 1747, that the earth itself and intervening bodies of water might be made use of to complete the electric circuit, was one important step toward this application. He transmitted shocks across the Thames and the New river, in one instance at Shooter's Hill the circuit being composed of 10,500 feet or about 2 m. of wire, and 2 m. of the earth; and he supported his wires, as now practised on the telegraph lines, upon posts. Signals were communicated by means of the electric shock from one apartment to another by Lesage at Geneva in 1774, and by Lomond in France in 1787, probably by causing the divergence of pith balls on some concerted plan; and in 1794 Reizen of Germany employed the electric spark for telegraphing, making use of an ingenious arrangement of lines and interrupted spaces upon strips of tin foil, so arranged that when these spaces were illuminated by the spark the form of the letter or figure was exhibited. He employed 37 wires from one station to another, each one of them communicating with one of the letters or figures, and each one connecting with a return wire, thus making 72 in all. This plan is described in vol. ix. of "Voigt's Magazine." Cavallo in his "Treatise on Electricity" (1795) suggests the explosion of gunpowder to call attention, and then the transmitting of signals by succession of sparks at intervals and in numbers according to the system agreed upon. Don Francisco Salva of Madrid and Sr. Betancourt constructed similar telegraphs at Madrid in 1797 and 1798, one of them extending between Madrid and Aranjuez, a distance of about 36 m. This, too, is noticed in vol. xi. of the work just referred to. Salva communicated his plans to the royal academy of sciences at Barcelona, and according to the journals of 1797 they were highly approved by the minister of state. Salva appears to have had a clear idea of the practicability of this electric communication even beneath the sea, and in the last of his memoirs he proposed to substitute the voltaic pile for the electrical machine. Other attempts to employ machine or friction electricity were made by Francis Ronalds at Hammersmith, England, in 1816, on a line of 8 m.; and in 1827 by Harrison G. Dyar at the race course on Long island, N. Y., on a line of 2 m. in length. The latter made use of iron wire, glass insulators, and wooden posts for supporting the wire, and employed the chemical action of the electric current to change the color of litmus paper as his method of communicating. Ronalds introduced the plan of employing a clock at each of the two stations, both of them running together exactly, and each bringing into view one after the other the letters of the alphabet arranged upon a disk which revolved behind a screen with an opening for one letter. Each clock was provided with two pith balls connected with the electrical machine at the other station; and as the shock was passed the divergence of these called the

attention of the other operator to the letter then in view. As the letters appeared in succession they spelled out the message communicated. The clock movement is an important feature in most of the modern telegraph systems. The voltaic pile, discovered in 1800, furnished in its constant current a more promising agent for transmitting intelligence than the sudden and transient shock of the electrical machine; and electricians were not long in testing its capacity for this purpose. Sömmering commenced his experiments in 1809, and devised a plan of telegraphing which was as perfect as was practicable in the condition of the science at that time. He made use of 85 wires, each terminating in a gold point, and all the points were set up vertically on a horizontal line at the bottom of a glass reservoir of water. In the other direction these wires, brought together in a tube, extended to the other station, where they again diverged, each one terminating in a brass plate, and the plates attached along a horizontal wooden bar. The plates at one end and the points at the other were marked with corresponding letters, and the current from the battery was established whenever two of the brass plates were touched, one with the negative and one with the positive pole. Decomposition of the water immediately occurred in the reservoir on the two corresponding gold points, the one producing hydrogen and the other oxygen gas, and the letters thus designated were noted down as part of the message communicated. Sömmering found that the addition of 2,000 feet of wire produced little or no sensible additional resistance, and that the galvanic action was instantaneously developed at least for the distance of about 8,000 feet. The galvanic batteries then known were however inapplicable to the transmission of currents through great distances, both on account of not continuing long in action, and also for want of sufficient intensity without using an inconvenient number of pairs; and no further progress was made in perfecting the electric telegraph until the principles of electro-magnetism had been developed. (See ELECTRO-MAGNETISM.) The first discovery in this branch of science was that by Oersted of Copenhagen, in 1819, of the electric current as it passes through a wire causing a magnetic needle near by to place itself at right angles to the current, and that the direction of the movement may be changed by changing the connection of the wires with the two poles of the battery. Schweigger of Halle in 1820 discovered the method of increasing the deflection by placing the wire that carries the current around the needle, and this improvement is adopted in all the telegraphs of this character. The same year Ampère laid before the academy of sciences at Paris the plan of a telegraph based on the movement of magnetic needles thus induced. Each needle was to stand for a separate letter or figure, and consequently a great number was required. The early telegraphs of

Prof. Steinheil of Munich, and of Cooke and Wheatstone of England, constructed many years afterward, were based on this principle, and were finally perfected by reducing the number of wires. Ampère and Arago also discovered and put in practice the method of magnetizing needles by passing the electric current in successive coils nearly at right angles around them, which is still employed in making magnetic needles for compasses, &c. These discoveries, though preparing the way for the electric telegraph, were yet insufficient; and the opinion was even expressed in 1825 by Mr. Barlow, of the royal military academy of Woolwich, that in consequence of the diminishing power of the galvanic current with the increasing distance, estimating the power from his experiments as the square root of the length of the wire, the construction of the telegraph over long distances was impracticable. This checked further attempts for a time. The next discovery of importance was that of Mr. William Sturgeon of London in 1825. By coiling copper wire loosely around a piece of iron wire bent into horse-shoe form, with the turns of the copper wire quite separate from each other, and transmitting through this the galvanic current, he magnetized the iron, and thus produced the first electro-magnet of soft iron. This, however, was not applicable to telegraphic purposes, as from the open manner of coiling the naked wire to prevent the spires coming in contact, sufficient power could not be generated through a long conductor to develop the magnetic action necessary for closing the circuit, and thus producing a motion at will. Prof. Henry, in his experiments made in Albany, N. Y., in 1828-'30, first employed a covered wire, which could be wound in successive layers upon itself round the whole length of an iron bar, either straight or bent into a U; and he thus succeeded in so multiplying the magnetic force, that with the use of a small battery magnets were made of a power never before known, and the current was so increased in intensity, that the electric telegraph was at once made practicable for any distance. Upon all the telegraph lines except Bain's these electro-magnets are indispensable. The progress of discovery had now demonstrated the practicability of moving at will a magnetic needle in one or the other direction, or of causing the armature of a magnet to be attracted and then released, and of repeating and varying these movements rapidly for any number of times through wires extending any distance. The possibility of an electric telegraph based upon either one of these two movements was thus established, and was recognized by electricians; but to perfect it ingenuity of a high order was to be called into play, together with patient study and much perseverance. The first person to apply to this object the discoveries so far made was the baron Schilling of St. Petersburg. He devised in 1832 a telegraph on the principle of deflecting magnetic

needles, each of which corresponded to a letter or figure, and was provided with its own wire of platinum insulated by being covered with silk, which wire surrounded the needle on the principle of Schweigger's multiplier. The several wires beyond the multipliers were brought together into one cord, and thence passed to the next station. It appears that he succeeded in reducing the number of needles, and finally employed but one. He also introduced an alarm at the commencement of the passage of the current by causing a solid body to fall, on the same principle as had been already recommended by Prof. Henry in his lectures. These promising experiments were unfortunately interrupted by his death, and the steps made were lost, without even a very accurate account being preserved of the results attained. The next experiments of importance were those of Counsellor Gauss and Prof. Weber of Göttingen in 1833 and 1834. They employed first galvanic electricity excited by numerous pairs, and afterward a magneto-electric machine to transmit signals from 9,000 to 15,000 feet. They caused a magnetic bar to be deflected to one side or the other, and interpreted its repeated movements into the letters of the alphabet; but no practical results followed their experiments. In 1836 the first form of the constant battery was invented by Prof. Daniell, supplying the means of keeping up a continuous current. This principle is universally adopted upon all telegraph lines, except those using the inductive current of Prof. Faraday's discovery, in the form of the magneto-electric machine. The first telegraph actually established appears to have been that invented by Prof. C. A. Steinheil of Munich in 1836, and adopted the next year by the Bavarian government. It extended a distance of 12 miles, employed but a single wire, and made use of the earth to complete the circuit. The signals were sounds produced upon a series of bells of different tones, which soon became intelligible to a cultivated ear; and the same movements that caused the sounds were also made to trace lines and dots upon a ribbon of paper moved at a uniform rate, on the same principle with the method devised about the same time by Prof. S. F. B. Morse. The generator employed by Steinheil was a magneto-electric machine on the inductive principle discovered by Faraday, but with the magnets stationary and the multiplying coils revolving close to them. A current of more uniform flow was thus obtained than could be had with the voltaic pile.—In 1837 several telegraphs were brought before the public in different countries, the production of independent inventors. That of Prof. Morse of the United States, which has continued to be generally recognized in all parts of the world as the most efficient and simple, was first publicly exhibited in the university of New York in 1837, and had been gradually brought to a working condition by experiments and

contrivances devised by the inventor since 1832, with the assistance of Prof. L. D. Gale and Messrs. George and Alfred Vail. In Oct. 1837, Prof. Morse filed a caveat in the patent office to secure his invention; and he obtained the patent in 1840, covering the improvements he had in the mean time made in the apparatus. The telegraph was first brought into practical use, May 27, 1844, between Washington and Baltimore. An insulated wire was first tried buried in a lead pipe underground, and failing was replaced with one on posts. The power was derived from a galvanic battery, and an iron electro-magnet was employed at the receiving station for developing its effects. With the armature of the magnet was connected first a pen with ink or a pencil for producing lines and dots upon a moving slip of paper, as the armature was drawn down to the two poles of the magnet on each closing of the circuit at the other station; the continued action of the battery causing a line to be drawn as the paper moved along, and the immediate breaking of the circuit after closing admitting of merely a dot. The combination of dots and lines to represent letters and figures, and the simplicity and efficiency of the apparatus for producing these, are the features which distinguish this from other telegraphs, which employ the armature movement instead of the deflection of the needle, and have led to the preference generally accorded to it throughout the world; and Mr. Morse is entitled to great credit for conceiving this plan with the use of only one wire so early as 1832, and steadily adhering to it until he had brought it to perfection. The apparatus was improved by the substitution of a sharp point for the pen or pencil, which is attached to one end of a lever, at the other end of which is the movable armature. The circuit is closed by the operator who is sending a message pressing with his finger upon a single lever connected at its fulcrum with one of the wires of the battery, thus bringing it in contact with the other pole, and the connection is instantly broken for a dot, or allowed to continue a perceptible period of time for a line. The paper of the registering apparatus is moved regularly along by clockwork. The signs for the letters in use for the English alphabet (which are variously modified to adapt them to other alphabets), and for the numerals and punctuation marks, are as follows, those most used, as will be noticed, being the simplest:

LETTERS.

The slightness of the difference, which cannot be avoided, between some of the signs, as in the O and S, I and O, L and T, &c., exposes to mistakes, which in case of writing in cipher cannot be corrected, and not always when the message is perfectly understood by the operator who sends it. Thus a merchant telegraphed from New Orleans to his correspondent in New York, to protect a certain bill of exchange; the word "protect" was read as "protest," and involved serious consequences to the parties interested. In the offices in the United States, where the Morse telegraph is employed, the recording instrument is now generally abandoned except at local and interior stations, and the operator trusts entirely to the sound caused by the opening and breaking of the circuit. This saves the expense of an extra assistant for reading the despatch to the copyist, the operator now writing down the messages as he receives them by the ear. Experience has proved that a much smaller number of errors are made in receiving by sound than by the former method of reading from the strip of paper.—What is known as the English telegraph is the result of the investigations and inventions of Mr. William F. Cooke, whose attention was directed to this subject in March, 1836, when a student at Heidelberg, by witnessing an experiment performed by Prof. Möncke of causing the deflection of a magnetic needle by the electric current. Though unacquainted with the subject, he immediately set himself to work to apply the principle to the telegraph, and in July of that year he produced an experimental instrument, which he not long afterward took to England and sought to introduce on the Liverpool and Manchester railway. He there became associated with Prof. Wheatstone, and the two united their labors to perfect the instrument. The first patent for an electric telegraph was issued to them on June 12, 1837. They employed 5 magnetic needles and coils, and either 5 or 6 wires, with a peculiar key-board previously invented by Prof. Wheatstone, upon which were arranged the letters, and these were designated in turn as any two of the needles arranged across the centre of the board pointed to one and another of them. The apparatus underwent various modifications in the hands of its inventors, and was much simplified by the use of only two needles, and finally of only one, which may be but a wooden pointer. This is arranged upon the middle of a vertical tablet through which the axis it turns on passes to the electro-magnet that is secured on the back of the tablet, and within which is the real needle that causes the movement. Letters are designated by the deflection of the needle to the right or to the left one or more times in either or both directions for each letter. The swinging of the needles is checked by small pins fixed on the dial, so that their motions are rendered precise and clear.

The magnetic coil has its own pair of wires, one end running into the ground and the other extending to the other stations, and with these wires are also connected the batteries, by which communications are sent. In case of accident to the wire of one instrument, that of the other serves to keep up the communication. Handles placed in front under the dial furnish the means by which the attendant can immediately connect the poles of the battery with the wires in either way, so as to cause the needle to move to the right or to the left, and by partially turning them instantly reverse the poles and consequently the direction of the movement of the needle; or he can by the same apparatus interrupt the connection of his battery with the wires, in order to receive communications. With each apparatus was formerly connected an alarum bell, the clapper of which was moved by a weight or spring connected with clockwork, on this being set in action by the electric current attracting the armature of an electro-magnet, and thus moving a lever that held the apparatus in check. This is now generally abandoned, the sound made by the click of the needle against the ivory studs that prevent its vibration being found sufficient. Prof. Wheatstone introduced one very important feature in the electric telegraph, which is a second battery for working the alarum, and which has since been applied to other purposes also requiring more power than that furnished by the first battery. It is brought into action by the deflection of a magnetic needle, the ends of which are thus placed in contact with the two wires of the second battery, and so close its circuit. When the current of the first circuit is interrupted, the needle swings back, breaking the circuit of the second battery and throwing it out of action. This is the principle of the relays employed to renew the power upon telegraph lines of great length. The telegraphs which are used upon the railways of Great Britain and by the "Electric Telegraph Company" are generally double, each employing its own wires. One of the needles then indicates by its movements the letters of one portion of the alphabet, and the other the remaining letters. Two handles in the lower part of the dial, one under each needle, serve for sending the messages. The needles upon the dial are moved by the messages sent as well as by those received, so that each operator may see the signals he makes. It thus appears that by the English telegraph no record is made by the apparatus itself of the message; the operator observes the signs, and notes them upon paper as they succeed each other. It is thence sometimes distinguished as the indicator telegraph, while the others are called registering telegraphs. Morse's telegraph may be one or the other, as it is used to prick the signals upon paper, or as the operator interprets them by their sound. With the English double-needle telegraph, employing two wires and two batteries

and other apparatus at each station, an expert operator can send as many as 150 letters a minute; but this is more than can be correctly read, the limit of which is about 100 letters a minute, and in actual practice the number is somewhat less than this, or from 17 to 24 words a minute. Operators accustomed to the work do not require the lettered dial for reading the movements of the needle.—Of the numerous telegraphic inventions that soon succeeded those already named, Mr. Alexander Bain's are particularly worthy of notice. He was engaged in England as early as 1840 in the production of a printing telegraph, and in 1846 patented what is known as an electro-chemical telegraph, the principle of which was first applied to this purpose by Harrison Gray Dyer in 1827, and by Mr. Edward Davy in England in 1838. Mr. Bain brought his new telegraph to the United States in 1849, and, after overcoming the opposition made against it on the ground of its infringing the Morse patent, it was brought into active operation upon several of the most important lines in the country, and was the means of reducing the cost of telegraphing 40 per cent. The two interests were afterward consolidated, and the Morse patent was adopted upon all the lines excepting that from Boston to Montreal. The Bain telegraph is remarkable for its extreme simplicity. No electro-magnet is required, the galvanic current passing through the wire from a distant station being sufficient to produce a distinct mark upon the chemically prepared paper interposed between the point or index at the break in the circuit and the extension of the wire into the ground. As this involves no change in the direction of the current, the same pole always remains connected with the earth, and the other (which must be the positive pole in order to produce a colored mark upon the paper) is brought into connection with the line by closing the circuit with the key. The paper is brushed over with a solution of 6 parts of prussiate of potash in water, to which are added 3 parts of nitric acid and 2 of ammonia. Thus prepared, and while damp, it is made to pass over a metallic roller; a fine needle or style presses gently upon the surface; a simple machine moved by clockwork to carry the strip of paper is all that is required. The branch or local circuit of Morse can be applied as well to this system for drop copies, or resistance coils can be used to effect the same object, producing with each closing of the circuit a line or a dot, on the principle of the Morse and other similar systems. As it makes its marks instantaneously, however, without the intervening movement of an armature, it may be made to communicate messages with much greater rapidity than the Morse telegraph. It is observed of this system that it is not in danger of disturbance during heavy thunder storms, which occasionally do serious injury to the operators as well as to the apparatus employing the electro-magnet; and sufficient

electric force to accomplish its work may be transmitted through the wire for long distances (as has occurred between New York and Boston), with the wire actually lying upon the ground during a heavy rain storm. So little power is required to work it under ordinary circumstances, that 10 cups of the Grove battery have been found sufficient between Boston and New York. This telegraph, like most of the others excepting the Morse, requires an alarm bell to call the attention of the operator when a message is to be sent from another station, and for this an electro-magnet is employed distinct from the registering apparatus. Mr. Bain made many other inventions in the telegraph, several of which are too remarkable to be passed over. One of these, adapted for transmitting words at the extraordinary rate of 5,000 per hour, employed at the sending station narrow strips of paper perforated with holes and elongated slits, making the message in these regular characters of the system. These strips (prepared beforehand) were passed in succession over a cylinder of metal with a pin connected with the wire so placed as to press lightly upon the paper and enter each hole as it passed along and complete through it the circuit. At the other station similar strips of chemically prepared paper were passed at precisely the same rate under the same sort of style as that just described, and colored marks were thus produced exactly corresponding to the holes in the paper at the transmitting station. The advantage of this system is in the transmission of very long messages which may be prepared in separate parts by a number of operators; or, as is now done, by the use of a very ingenious machine which perforates the paper with great rapidity, as it is worked by striking keys like those of a piano. The difficulty in the practical application of this telegraph appears to be the want of some efficient means of exactly regulating the speed of the apparatus. The universal telegraph of Prof. Wheatstone, recently introduced in London, is based on this principle. Another of his inventions was a printing telegraph, in which types arranged around the periphery of a wheel were brought successively opposite the face of a cylinder covered with paper and instantly pressed against it, while the cylinder turned at a regulated speed around its axis, and at the same time was carried longitudinally along it so that the printed lines passed in spirals from one end of the cylinder to the other. The electric current caused the rotation of the wheel having the types, and also stopped or liberated the other movements which depended upon springs and clockwork. The machines at the different stations are precisely alike, and all their movements are perfectly synchronous. A printing telegraph of somewhat similar construction was invented in 1837 by Mr. Alfred Vail of New York; and others have been produced by M. Froment in France, Royal E. House of Vermont, David E. Hughes of Kentucky, and Jacob Brett in Great

Britain. Some of these will be noticed further on.—An electric copying telegraph was invented by Mr. F. O. Bakewell of England in 1850, designed for giving an exact copy of the message sent. This is written with a pen dipped in varnish upon a sheet of tin foil, which is then laid around a metallic cylinder, corresponding precisely in its size, rate of revolution, and longitudinal movement, with another cylinder at the receiving station, which is covered with chemically prepared paper and provided with an index like that of the Bain chemical telegraph. These cylinders being set in motion at the same instant, the index of the registering apparatus makes a continuous colored line, running round the cylinder in a close spiral so long as the metal style at the other station presses upon the tin foil; but as this passes over the lines of varnish a break in the circuit occurs, causing an interruption of the colored line at the other station. The blank spaces thus produced will be found when the lines have been drawn over the whole paper to be a facsimile of those written in varnish upon the tin foil. The lines, though drawn as spirals upon a cylinder, appear as parallels when the paper is taken off. About 10 revolutions of the cylinder, making as many parallel lines, are sufficient to complete one line of writing; a cylinder 6 inches in diameter affords sufficient length for about 100 letters of the alphabet in one line; and as the rate of revolution is not less than 80 in a minute, 800 letters or more may be transmitted in this period. A message in cipher can be sent by this method without risk of error, and even invisible messages written in colorless varnish may be received and impressed in invisible characters upon prepared paper, to be afterward brought out by chemical means; thus, if the paper be moistened with diluted acid alone, no visible mark is left upon it until it is brushed over with a solution of prussiate of potash, when the lines appear in their blue color.—The patent for the House printing telegraph was issued by the U. S. patent office in 1848, but bears date April 18, 1846, when it was first applied for. It was with this apparatus that the first printed despatch ever produced upon a telegraph line was sent, in the autumn of 1847, from Cincinnati to Jeffersonville, opposite Louisville, Ky., 150 m. The system is regarded as one of the most wonderful and complete of the extraordinary inventions developed by the telegraph. The necessity of avoiding the peculiar features upon which other telegraphic systems were established, in order to give to it a distinctive and patentable character, added greatly to the difficulties of the undertaking, which however were after nearly 6 years of labor overcome by the ingenuity and perseverance of Mr. House. The apparatus is too complicated for any description of it to be made intelligible without illustrations, and little more can be attempted than to state its great powers of execution and its perfect accuracy. The mechanical move-

ments of this machine are set in action by hand labor applied to a crank, which works an air pump for the purpose of supplying a current of condensed air, which under the control of the electric current carries forward the movements of the composing and printing apparatus, so that each letter may be printed at the exact instant that it is struck upon the key-board of the instrument. This key-board, which resembles that of a piano, is connected with the electric current, and as the keys are struck the circuit is opened and closed with the movements of a circuit wheel which controls the movements of the type wheel. A complete revolution of the circuit wheel, coming round again to the same letter, breaks and closes the circuit 28 times, and other letters a less number according to their arrangement on the type wheel. The printing apparatus is quite distinct from the circuit, but the composing apparatus forms a part of it. The impression of the letter is produced by a blackened ribbon being pressed against the paper by the type. From the galvanic battery of one station, the current passes along the wire to the next station, then through the coil of an axial magnet to the insulated iron frame of the composing machine, and thence to a circuit wheel revolving in this frame. Through a spring that rubs on the edge of this wheel it passes into the return wire, and through another battery back to the first station to pursue the same course through the composing machine and magnet there and all others upon the line. In sending a message, the operator sets his machine in motion and gives a signal by breaks of the circuit, repeated a different number of times for different offices on the same wire. As this is heard by the operator at the receiving station, he sets his machine in motion, and the type wheel at its starting point, and signals back that he is ready. No further attention is required on his part, while the machine goes on, printing in Roman capitals the communication upon the long strip of paper regularly supplied to the type wheel. Two hundred and fifty to 260 letters as a maximum can be accurately printed every minute, and over 3,000 words an hour of press news, partly abbreviated, have been sent over the wires with a single instrument.—The inventions of Mr. Hughes, patented May 20, 1856, showed that the field of discovery in telegraphing was far from being exhausted, by introducing apparatus even more wonderful in its operation than any which had yet preceded it. His was a printing telegraph, in which the feat of printing a letter with every impulse or wave of the electric current was accomplished. In the other telegraphs, as already described, several impulses produced by successive closings or breaks of the circuit are required to form a single letter; this in House's telegraph varies up to 14 breaks, the maximum required for repeating the same letter, and averages about 7 impulses; and in the Morse system the average is about $8\frac{1}{2}$ impulses, some of which making lines
